Case 7.—F. A., woman, aged 25, admitted, July 27, 1917, had had the forearm severely lacerated up to the elbow by getting it caught in a steam roller, six months previous to admission. At the time of admission the hand was bound down in flexion by tendon contracture. The metacarpal joint was in strong hyperextension. There was flexion of the middle and end phalanges and pronation. July 28, 1917, plastic lengthening of the flexor muscles of the wrist and fingers was performed. Complete extension of the wrist and complete extension of the fingers was obtained after this operation, but the hyperextension in the metacarpophalangeal joint was not improved. For the relief of the latter condition two further operations were performed, both intending to relieve the contraction of the finger extensors over the joint by tendon lengthening. But the extensor muscles of the fingers were found transformed into a mass of scar tissue in which the individual tendon could not be differentiated. Finally, as both attempts failed to release the contracted joint, the plan of Dr. R. Meisenbach for a similar condition in claw foot was adopted. A longitudinal incision was made over the dorsum of the first, second and third metacarpals, and an osteotomy was performed, about one-half inch proximal to the joint. The fingers were then bent down forcibly, allowing the fragments to kink. In this way a better closure of the fingers was obtained, although the metacarpophalangeal joints themselves remain unchanged. The result of this operation has been much more satisfactory.

PROBLEM 3. RECONSTRUCTION WORK OF THE THUMB

Reconstruction work of the thumb was carried out for the relief of (1) inability of opposition of the thumb, and (2) inability of extension of the thumb. In the first instance the gripping power of the hand is greatly impaired, as the thumb cannot be used to oppose the fingers, while in the second instance the gripping power of the hand is also impaired by the fact that in closing the hand the thumb is thrown under the fingers, preventing the hand from taking hold of any object (six cases).

CORRECTION OF INABILITY TO EXTEND THE THUMB

Case 10.—A. R., boy, aged 12, admitted, Jan. 18, 1917, had spastic paralysis. The hand was only slightly paralyzed, with the exception of the extensors of the thumb. The thumb was drawn under the fingers each time the patient closed his hand. Feb. 12, 1918, after the technic given by Biesalski and Mayer, an incision was made over the extensor indicis proprius of the right hand. The tendon was split at the metacarpophalangeal joint, brought out through a second incision over the long extensors of the thumb, and then fastened to the tendon of the long extensor of the thumb. After the operation the patient ceased to turn the thumb under in closing the hand, and opposition of the thumb and fingers was thereby secured.

PLASTIC SUBSTITUTION OF RUDIMENTARY THUMB

Plastic substitution of the missing thumb was carried out first by Nicoladoni, who reported two cases in 1900 and 1903. Later Schepelman, Horhammer and others reported on cases of this kind. Nicoladoni's autoplastic substitution was carried out in two step operations, the second toe of the same side being used for the substitution of the missing thumb.

Case 14.—R. G., boy admitted, Nov. 14, 1917, with a club hand deformity. Acording to the statement of the mother, there was an infection of the hand very early in life, followed by almost complete loss of the thumb and destruction of the distal end of the radius. On admission there was found on the radial side of the wrist a scar, to which a very rudimentary thumb, not more than one-half inch long, was drawn laterally and backward. The muscles of the thenar were preserved. The club hand deformity was corrected, Dec. 6, 1917, by resection of a piece of the ulna.

The first step of the plastic substitution of the thumb was carried out, March 5, 1918, as follows (Dr. Charles J. Rowan, assisting): A flap was prepared by a dorsal curved incision, from the dorsal surface of the thenar and the adjacent side of the wrist. Then the stump of the metacarpal bone was dissected, and the end refreshened and anchored by catgut sutures. A U shaped flap was then prepared over the seventh rib of the left side of the chest, with lateral base. Under this flap 1 inch of the rib was resected. As it was impossible to keep the rib in connection with the flap, it was removed and immediately fastened to the stump of the first metacarpal by heavy double catgut sutures. The thumb was then pulled over toward the chest, and the skin under the flap was drawn together and sewed. The flap of the chest was pulled over so as to cover the flap made from the dorsal surface of the thenar, with the implanted piece of the rib between the two flaps.

Twenty-three days later the second step of the operation was performed, by severing the flap from its base on the chest and trimming the tip of the new formed thumb.

The patient is now able to close his thumb against the tip of the fingers and to take hold of light objects.

MUSCLE EDUCATION

From the beginning of the work of reconstruction of the upper extremity, great stress was laid on the mechanical and muscle educational side of the aftertreatment. It is of considerable advantage in working on the upper extremity that there is no weight bearing and gravity to reckon with, and that the extremity can be readily protected against any undue influences of mechanical character. In every case the medicomechanical and later the reeducational treatment was added to the surgical corrective treatment, the work beginning from one to three weeks after operation.

Following the conclusion of medicomechanical treatment, the patient enters immediately on the muscle educational work. The nurse is instructed in regard to the needs of the individual case. The work is done in groups of five or six and sometimes more, but each patient does individual work and has individual attention. No special attention is paid to the product itself which is turned out by the individual child. The children are to be taught to use their hands in a certain way most favorable to the development of power and coordination of the muscles in question.

The work begins by molding in clay, for which common plasticine is used. This has proved especially useful for those patients who need thumb practice, as the molding requires quite a little muscular strength. I believe this to be by far the most useful part of muscle educational training because the movements required are simple and more or less elementary: kneading, twisting, pressing, etc. Children with more advanced functional ability of the hand are then given instruction in raffia work, which is especially beneficial for the more coordinate movements of the wrist and hand.

Weaving, even if the pattern is very simple, requires more skilful use of the hand, and naturally only a few of the children mentioned here are capable of carrying on this kind of work. Aside from these three essential instructions, the children are given all the encouragement in the use of such playthings as might help to develop the muscles of the hand, such as blocks and puzzle pictures.

All the patients mentioned have taken part in muscle educational work and have derived considerable benefit from it.

ABSTRACT OF DISCUSSION

Dr. John L. Porter, Chicago: Dr. Steindler's work is of inestimable value as illustrating what can be accomplished by a conjunction of correct mechanical principles and good surgery. I believe that we have been deterred from what, in the way of plastic surgery, might be very beneficial, because we have overestimated the anatomic difficulties and have decidedly underestimated the great many mechanical advantages to be secured. In one case I had great difficulty in preventing adhesions of the tendons, especially on the flexor surface of the wrist. I believe that adhesion occurred in this case because so many tendons are massed in so small an area, with very thin layers of tissue separating them. That is but one feature that prevents successful plastic work on flexor tendons. Our knowledge of this kind of surgery, and especially of the arm and wrist, will increase wonderfully from now on because the war is going to bring to our attention a lot more disabilities of the upper extremities from injury of nerves and muscles than we have seen before. Perhaps we have been deterred from doing what we could for paralytic conditions because they were paralytic; but when the cases are traumatic, we think that something must be done to insure return of the use of the hand, arm and wrist.

Dr. John P. Lord, Omaha: I believe that Dr. Whitman was entirely right in his conception of the principle of arthrodesis for stabilizing the ankle joint, and thus rendering more efficient any tendon transferences in cases of flail joint. It has seemed to me that this principle applied to the wrist would save us much of the more complicated and difficult part of this reconstruction of the structures about this joint. I have had considerable experience in resections of the wrist joint, and arthrodesis of that joint, done primarily to enable me to get better functional results after work on the tendons. It has also enabled me to lessen the spasms, which are attended with certain disadvantages. In Volkmann's ischemic paralysis I have on several occasions shortened the radius and ulna. I can testify to the efficiency of that method and its advantage. I can testify to the difficulties of plastic operations on tendons about the wrist, which cases furnish many complications. I think that if we would give more attention to the correct position, by operation on the bones and joints, and secure an arthrodesis in certain of these cases, we could then, by palliative methods, after a long period, secure results that might be superior to those obtained by the more extensive complicated operations on the tendons. It has been my experience that these operations about the thumb for the transference of tendon and muscle function have been very satisfactory. They lend themselves very well to the particular deformities of the thumb resulting from paralysis, more especially as it is sometimes necessary to rotate the bone after osteotomy. I found that I could get much better mechanical position by rotating the bone so that I could get a better application of muscle power.

Dr. Melvin S. Henderson, Rochester, Minn.: In wrist drop due to paralysis of the musculo-spiral nerve, nerve regeneration by operation has been attempted. I recently had an opportunity of visiting the Military Orthopaedic Hospital at Toronto, which harbors 750 patients, wounded Canadian soldiers. They told me that operations for severance of the musculo-spiral nerve were generally unsatisfactory. They are inclined to believe that better results will be obtained in these cases if tendon transference of the flexors to the extensors of the wrist is done instead of the nerve anastomosis, especially if there is a defect of any extent in the nerve. Recently I operated on a man with complete wrist drop, transferring the flexor carpi radialis and flexor carpi ulnaris to the extensor tendons of the wrist. The man can now extend the wrist and has good grasping power, whereas before he could not extend the wrist and could grasp objects only in a very awkward manner. I have seen quite a number of anastomoses for division of the musculo-spiral nerve, but have never seen a good result. Therefore, it would seem as though better results would be obtained in wrist drop by transferring the flexor tendons to the extensor tendons than would be obtained by any operation on the nerve.

Dr. Charles M. Jacobs, Chicago: A man, over 40 years of age, had a Dupuytren contraction involving the ring and little fingers. I made a careful dissection of the palmarfascia, but was unable to straighten out the little finger because of a shortened tendon; so I did a tendon lengthening. Following the operation a plaster cast was applied to hold the little finger in the extended position. The cast extended only up to the wrist. Several weeks later I noticed that the patient's hand dropped and that he was unable to extend it. The cast was taken off and I found that he had a flaccid paralysis, quite different from the ischemic paralysis which sometimes follows the application of a cast. I should like to ask whether Dr. Steindler applies casts following his operations and if he has had an experience similar to mine.

Dr. Arthur Steindler, Iowa City, Iowa: I appreciate Dr. Porter's difficulties regarding adhesion of the flexor tendons. Since I have been doing an arthrodesis I have had much less occasion for flexor transplantation. The flexor tendons are not as suitable for transplantation as the extensors. I have, however, united the tendon of the flexor carpo-ulnaris, leading it through the interosseus ligament to the extensors of the fingers after the stability of the wrist has been secured. Otherwise, I should not consider this a good procedure. While I have not had excellent extension, I obtained sufficient extension power in the first case so that the patient could freely open and close the hand. In reply to Dr. Lord, I would say that I have already stated what he did regarding stability of the wrist. I have no experience with rotating the bone; but in those cases in which the apposition of the thumb was missing on account of paralysis of the thenar muscles, I got good results so far with the plasty of the pollicis longus, which I have demonstrated. We had not only the wrist drop, but also the opposite deformity, in infantile paralysis.

VENEREAL DISEASE IN THE THIRTY-NINTH DIVISION *

LOYD THOMPSON, Ph.B., M.D.
HOT SPRINGS, ARK.
AND
J. R. BOLASNY, M.D.
DETROIT
Major and Captain, Respectively, M. C., U. S. Army

The problem of venereal disease in the Thirty-Ninth Division is similar to that in any other divisions in training at the various cantonments. The Thirty-Ninth Division is located at Camp Beauregard, which is situated about 5 miles from Alexandria, La., and is made up of the National Guard troops of Louisiana, Mississippi and Arkansas, augmented by draft troops from these states.

At first, as would be expected, by far the greater number of venereal cases were old ones brought in by the men from other cities. Later on, especially after the quarantine which existed between the camp and Alexandria on account of meningitis was lifted, the percentage of new cases began to rise.

PROGRAM OF ATTACK

In the handling of the venereal problem in the Army, a certain program of attack has been prepared in the Surgeon-General's Office and is being carried out. This consists of public as well as personal measures, and is briefly as follows:

Public Measures.—A. Social measures to diminish temptations: 1. The suppression of prostitution and the liquor traffic in the extracantonment zones. 2. The provision of proper social surroundings and recreation.

B. The education of soldiers and civilians: 1. The education of soldiers is accomplished by: (*a*) lectures, (*b*) pamphlets and (*c*) exhibits. 2. The education of civilians is accomplished by the same measures through such organizations as the Young Mens Christian Association, the Young Woman's Christian Association, the Women's Christian Temperance Union, and the General Federation of Women's Clubs.

Personal Measures.—A. Instruction in prophylaxis.

B. Prophylaxis stations: 1. Regimental infirmaries. 2. Civil centers.

C. Medical care.

WORKING OUT OF THE PROGRAM

In the handling of the venereal problem in the Thirty-Ninth Division, nearly all of these measures have been carried out to a greater or lesser extent. An officer of the Sanitary Corps has been detailed by the Surgeon-General's Office for work in the extracantonment zone. A certain amount of cooperation has been given by the city authorities in the matter of the suppression of prostitution. This has consisted mainly in the closing of most of the houses of prostitution in the so-called segregated district. We have been informed by the officer of the Sanitary Corps referred to above that this has been done in a half hearted manner, and that at least one notorious house has remained open. We have also been informed that while many women have been arrested for violation of moral ordinances, there have been no facilities at the city jail for housing them, so they have been allowed to go free with the promise that they leave town. We have also been informed that in the matter of regulating the illegal sale of liquor to soldiers there has been a great deal of laxity.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

It was hoped that a hospital for the treatment of prostitutes suffering with venereal diseases would be established, and the city authorities offered to furnish a building for this purpose if the parish authorities would maintain it. As yet this has not been done, and we have been informed that it probably will not be.

In the matter of providing proper social surroundings and recreation, the Army Y. M. C. A. has been of the utmost value in the camp itself, while the officer in charge of the work of the commission on Training Camp Activities has furnished more or less healthful recreation for the enlisted men, although the officers have had to shift for themselves to a greater or lesser extent. We wish to go on record in saying that the young unmarried officer needs healthful recreation as much as the enlisted man.

In the matter of the education of soldiers, lectures dealing especially with the methods of instructing men in venereal matters were delivered by the chief of the venereal service to all of the officers in camp. Illustrated lectures were also delivered to all of the men in the camp in regimental units, and these were supplemented by instruction by the company commanders. Small pamphlets dealing with venereal disease were also distributed to all men of the camp.

The education of the civilians in the extracantonment zone in venereal matters has been nil as far as we have been able to learn.

Of the personal measures of prophylaxis, as mentioned above, the soldiers all receive more or less instruction in prophylactic measures, and are warned that while the prophylactic measures protect the individual from venereal disease in the majority of cases, if taken in time, they are not absolute preventives.

Prophylactic stations have been established in all regimental and similar unit infirmaries where the prophylactic treatment can be obtained at any time day or night. The advisability of establishing a prophylactic station in Alexandria under military control has been recommended by us and is to be put into execution in the near future.

Army Regulations provide that a man who exposes himself to the danger of venereal disease, and who fails to take the prescribed prophylaxis, shall be tried by court martial.

MEDICAL TREATMENT

In the medical care of venereal disease, all cases are supposed to be first referred to the venereal service of the base hospital for diagnosis. Orders have been issued by the division surgeon that all men with urethral discharge be sent to the base hospital for microscopic examination of a smear, and all men with genital or other suspicious looking sores be sent without treatment for dark field examination. Before this order was issued, quite a large number of chancres were cauterized in the regimental infirmaries before the men were sent to the base hospital, rendering the finding of spirochetes impossible, and also a considerable number were so treated and syphilis not diagnosed until the secondary rash appeared.

Following the examination, men with acute gonorrhea enter the hospital and are treated there until the discharge diminishes, when they are returned to duty and their treatment continued in the regimental infirmaries under the direction of the chief of the venereal service. Chronic gonorrheal urethritis and complications of gonorrhea are treated either in the base hospital or the regimental infirmaries as the chief of the venereal service directs.

Cases of chancroid are treated in the base hospital until cured. Uncomplicated cases and complicated ones when the patients are convalescing are sent to the convalescent ward for housing and report to the venereal clinic for treatment at specified times.

All syphilitics are treated at the base hospital throughout the course of their treatment, although they are kept in the hospital only during the actively infective stage, that is, while they have open lesions. At other times they remain on duty and report for treatment at specified times.

One of us[1] has advocated a plan for the handling of venereal disease which we consider will very materially increase the efficiency of the venereal service. Briefly, this plan consists of establishing a venereal dispensary at a convenient location in the camp where all cases of venereal disease which do not need hospitalization can be treated. This plan with certain modifications has been adopted by the Surgeon-General's Office and is to be put into effect at Camp Beauregard.

In the treatment of gonorrhea, we have not departed strikingly from the classical methods. In all acute cases the men are placed in bed on liquid diet for twenty-four hours and then on light diet. The urethra is flushed once or twice daily, depending on the severity of the condition, after urination, the patient being put in a recumbent position, with a warm solution of potassium permanganate, 1:10,000. Then a 5 to 25 per cent. solution of silver "nucleinate" is instilled into the anterior urethra with an all glass syringe having a rubber tip. Rising from the table, the patient holds the solution in the urethra for from three to five minutes, when it is voided into a commode and the patient returned to bed.

In the more virulent infections the urethra is not irrigated at first, the penis being held in hot salt solution several times daily and a hot water bottle applied until the inflammation subsides, when the irrigations and the instillations are begun. Internally, sandalwood oil and large quantities of water are administered, and sedatives when required.

When the purulent discharge begins to disappear, the patient is sent to duty with the recommendation to his regimental surgeon that mild astringent solutions of zinc sulphate and lead subacetate be employed.

Recently we tried in selected cases a 1 to 5 per cent. solution of dichloramin-T in liquid petrolatum. The stronger solution proved too irritating to the urethra, but the 1 per cent. solution is giving rather encouraging results. In most of the acute cases and in some chronic ones the purulent discharge disappeared more promptly than with some other methods.

In acute posterior urethritis and acute prostatitis, the patient is put to bed, and heat is applied to the parts, with hot rectal irrigations and anodynes when needed.

Acute epididymitis is treated by placing patient in bed with the scrotum supported and an ice bag applied. In some cases the scrotum has been incised and the epididymis punctured with gratifying results.

---

[1] Thompson, Loyd: A Plan for the Better Handling of Venereal Disease in the Army, Mil. Surgeon, to be published.

Chronic gonorrheal infections of the urethra and prostate are treated in the usual manner with irrigations, instillations and prostatic massage.

In the treatment of chancroid we have found dichloramin-T in 5 per cent. solution applied as a wet dressing of considerable advantage in cases in which there is marked secondary infection. Other cases have been treated by simply cleaning them thoroughly, touching them with 10 per cent. silver nitrate and applying sterile petrolatum, while still others have been thoroughly cauterized with nitric acid, silver nitrate stick or the electric cautery.

In the treatment of chancroidal bubo, dichloramin-T has also been of distinct advantage.

Two plans for the treatment of syphilis have been used. At first we pursued the method of treating all syphilitics by giving weekly injections of 0.4 gm. of arsphenamin intravenously and 65 mg. of mercuric salicylate intramuscularly for six weeks. If this cleared up the symptoms, a Wassermann test was made one month after the last injection. If this was positive, another course of six injections each of arsphenamin and mercury were given, followed by another Wasserman test in one month.

If the test is negative after either course, a test is taken at monthly intervals, and if it again becomes positive the course is repeated.

Recently we have been treating all so-called primary and early secondary cases by giving five daily injections of 0.4 gm. of arsphenamin and repeating the course in one month with weekly injections of mercuric salicylate until symptoms of ptyalism appear. Of course, the mouth hygiene of all patients is attended to. In all old cases of syphilis, potassium iodid is given in rapidly increasing doses until symptoms of iodism appear.

CASES IN THE THIRTY-NINTH DIVISION

In the venereal service of the base hospital, during the eight months, September to April, inclusive, 605 cases of venereal disease were treated, of which 325 were gonorrhea and its complications, 25 chancroid, and 255 syphilis in all stages. These figures do not include all venereal cases of the division; quite a large number of cases of gonorrhea have been treated in the regimental infirmaries, and we have been unable to secure accurate data on them.

The accompanying table shows by months the number of acute cases of venereal disease which developed in the division, the rate per thousand and the number of venereal prophylactic treatments administered.

It will be noted that the largest number of new cases developed in November, when there were fifty-eight, and the smallest number in February, when there were but two. At first glance it would seem that the small number of cases in February was due to the quarantine between the camp and Alexandria, and probably it was indirectly due to that cause. On the other hand, it will be noted that a comparatively large number (399) of venereal prophylactic treatments were administered in February. In all probability this was due to the fact that while the men were not permitted to go to Alexandria, where they would be easily arrested by the military police, they were able to leave the reservation, and in spite of all that the authorities could do, prostitution flourished in the woods near the camp. Furthermore, it was usually necessary for the men to return to camp as quickly as possible, and they reported to their regimental infirmaries for prophylaxis much sooner after intercourse than when they went to Alexandria, and therefore the prophylaxis was that much more efficacious.

Of the 325 cases of gonorrhea and its complications treated in the venereal service of the base hospital, 100 were acute urethritis; 151, chronic urethritis; 41, epididymitis, acute and chronic; 5 prostatitis (this does not include the large number of cases of urethritis with more or less prostatic involvement); 22, cases of arthritis; 4, cases of stricture, and 2, cases of periurethral abscess. The longest incubation period recorded was nine days, and the shortest, thirty-six hours, with an average of four days.

The average incubation period of the twenty-five chancroid cases was eight days, the longest period recorded being sixteen days, and the shortest, two days. Six cases presented single sores, while nineteen were multiple. Eleven occurred on the prepuce alone, and one on the frenum alone. Three patients had sores on the glans penis and prepuce, and two on the glans penis, prepuce and balanopreputial fold.

In four cases there was no complication, in eight there was a bilateral inguinal adenitis, in four a right inguinal adenitis, and in three a left inguinal adenitis. In four cases there was a phimosis; three cases were complicated with syphilis and nine with gonorrhea.

ACUTE CASES OF VENEREAL DISEASE IN THE THIRTY-NINTH DIVISION

Month	Cases, Number	Rate per Thousand	Prophylactic Treatments, Number
September	30	10.53	247
October	29	4.57	342
November	58	2.90	744
December	31	1.40	350
January	26	1.13	99
February	2	0.088	399
March	19	0.87	866
April	12	0.55	470

Of the 255 cases of syphilis, 32 were primary; 155, secondary; 22, tertiary; 40, latent, and 4, cerebrospinal, including 1 paretic and 1 congenital.

Of the 32 primary cases the chancre was located on the balanopreputial fold eighteen times; the shaft of the penis, eight times; the frenum and the glans penis, twice each, and the scrotum and prepuce once each. In the remaining 233 cases, the location of the chancre, as obtained by noting the scar or from the history, was: balanopreputial fold, 31 per cent.; glans penis, 27 per cent.; shaft of the penis, 14 per cent.; prepuce, 11 per cent.; frenum, 5 per cent., and scrotum, 3 per cent. In two cases, or 0.9 per cent., the chancre occurred at the meatus, and in two more cases there had undoubtedly been a urethral chancre. In two cases of early secondary syphilis, extragenital chancres were seen. One of these was on the lower lip and the other on the cheek. The one on the cheek was seen before the secondary rash had developed, and was diagnosed clinically as syphilis; but as spirochetes could not be demonstrated after repeated trials, and owing to the fact that our Wassermann tests had to be sent to the department laboratory in Atlanta, taking from one to two weeks for an answer, treatment was withheld from this case until the secondary rash developed. The source of infection in this case was possibly an infected razor, as the patient stated he had used a razor belonging to a man he afterward learned had syphilis about two weeks before the development of the sore. Since this case was seen the laboratory of the base hospital has become equipped to perform the Wassermann test.

It is rather interesting to note the source of infection in all of these cases, that is, where the soldier was when he contracted the disease. Of the 255 patients, 111, or 44 per cent., contracted the disease before entry into the military service; 39, or 16 per cent., contracted it after being mobilized in the smaller towns of their states as follows: 20 in the towns of Mississippi, 10 in the towns of Louisiana, and 9 in the towns of Arkansas; 58 patients, or 20 per cent., became infected in the large camps as follows: 25 each in Jackson, Miss., and Little Rock, and 8 in New Orleans; 12 cases, or 5 per cent., were contracted in Alexandria. In 17 cases, or 7 per cent., the place of infection was unknown, but must have occurred since entry into the service.

The most striking figures, however, are those of eighteen cases, or 8 per cent., which were contracted while the victims were on furlough. The reason for these comparatively large figures is that men on furlough usually are unable to take the venereal prophylaxis.

The reason for the larger figures in the mobilization camps, both in the small towns where the National Guard companies were mobilized, and in the larger camps, is probably to be found in the fact that the prophylaxis rule was less strictly enforced than in Camp Beauregard.

The incubation period of the syphilis cases was unknown in thirty-four. The shortest time recorded was two days and the longest twelve weeks, while the average was twenty-two and one-half days. It is realized that in both the shortest and the longest period recorded the patients' statements are not to be taken as absolute proof of such incubation, but in both cases repeated questioning failed to bring out other evidence.

Of the syphiloderms, the macular, roseolar type was observed 45 times; the papular, lenticular, 49 times; the moist papular or condylomatous, 10 times; pustular lesions, 6 times; palmar and plantar syphiloderms, twice each; the macular, pigmentary lesion, twice; gummas of the skin, twice, and rupia and verruca, once each.

Mucous patches of the mouth were seen fifty-three times; ulcerating gummas of the mouth, three times, and leukoplakia, once.

Marked alopecia was seen three times.

Ten cases of syphilitic arthritis were observed. This condition was diagnosed only on finding definite joint changes with the roentgen ray, or when the subjective symptoms improved under specific therapy.

Only one case of syphilitic periostitis was seen; this was of the frontal bone. Syphilitic retinitis was seen five times, and two cases of syphilis of the stomach were diagnosed.

One case each of gumma of the testicle and gumma of the submaxillary gland was observed.

It is impossible as yet to draw any very definite conclusions from our treatment. However, we have been able in 102 cases to make Wassermann tests one month after the course of six injections of 0.4 gm. of arsphenamin and 65 mg. of mercuric salicylate. Of the 102 cases, fifty-six, which before treatment gave a ++ Wassermann (complete inhibition) gave a negative reaction after treatment, and all but one remained negative for periods of from one to six months. In one case a ++ was recorded two months after the negative had been obtained. One case of primary syphilis which gave a negative reaction both before and after treatment was ++ four months later.

In ten cases the ++ was reduced to a + by the treatment, and in three of these to a negative reaction by one more course. In fifteen cases a ± was obtained after treatment when a ++ was recorded before, while twenty-one cases still showed a ++ after the first course. Six of these showed a negative reaction after a second course.

A sufficient time has not elapsed to observe the effect on the Wassermann test of the more intensive methods of treatment, that is, five injections of arsphenamin on five successive days and a repetition of the course in one month with mercury to the point of salivation.

Of the 255 syphilis patients, thirty-five have been discharged from the Army on surgeon's certificates of disability. In thirty of these the disability was due to some manifestation of syphilis which did not yield to treatment, the other five patients being discharged for other causes.

SUMMARY AND CONCLUSIONS

The venereal problem in the Thirty-Ninth Division is similar to that in other cantonments.

There has not been the whole-hearted support of the citizens and authorities of Alexandria in minimizing the amount of venereal disease that has been shown in some cantonment cities.

The venereal prophylaxis as administered in the Thirty-Ninth Division has proved quite efficacious in preventing venereal disease.

The venereal prophylactic station in Alexandria under military control is to be established.

The use of dichloramin-T is of advantage in the treatment of certain cases of gonorrhea and chancroid.

The best method of treating early syphilis (primary and early secondary) is probably the daily injection of 0.4 gm. of arsphenamin for five days, repeating the course in one month, with weekly injections of mercuric salicylate to the point of salivation.

ABSTRACT OF DISCUSSION

Dr. William T. Belfield, Chicago: The United States Regular Army has been notorious the world over for its excessive venereal rate. Excluding the Philippines and China, where the rate was much higher, from 1906 to 1911 the home army averaged about 150 men per thousand per year of venereal infection. During that same period the venereal rate in the Japanese and French armies at home ranged about twenty-four, and in the Prussian and Bavarian armies, under twenty. In 1909 a timid attempt was made to introduce the so-called prophylactic treatment. Our medical men have always been regarded by the line officers as poor relations who are useful in the treatment of the sick and the wounded, but not used in their equally important function of preventing preventable disease. In 1909 the prophylactic treatment was really a joke. They used to furnish the soldiers with a packet shaped much like a cigar, and the soldier was instructed to use it after exposure. He was not commanded to use it; he could use it or not, as he pleased; and usually he did not please.

In 1912 the Army authorized the use of the prophylactic treatment not by the soldier himself but after his return to camp; and from that year on the venereal rate dropped in the Regular Army from 150 to 90 per year. According to the bulletins issued by the Surgeon-General's Office it would seem that the regular troops in this country are still averaging about 90 infections per thousand per year.

Undoubtedly the chief reason for this excessive venereal rate is our inefficient use of the prophylactic treatment. It has been shown that when properly used in the infirmaries within an hour after exposure, that treatment constitutes an almost complete prevention. Thus, of 1,180 men who received the treatment within sixty minutes after exposure, only one showed venereal infection; 1,172 received treatment between one and two hours after exposure; of these seven were infected. Of those who received the treatment between seven and eight hours after exposure, the rate per 1,180 had run up to forty-eight. It would seem that if we cannot bring the man to the treatment within sixty minutes, the treatment ought to go with him; and he should not only be told to use it, as he was in the old days, but court-martialed if he does not use it. He is court-martialed now if he fails to report the exposure and then develops infection. An anilin dye in the ointment would reveal his failure to use it.

Dr. F. M. McCallum, Kansas City, Mo.: While the teaching propaganda which is prevalent through the country is of great value, in many ways I do not think it would be anything like prophylactic. When I was in Honolulu in 1907-1909, the Preachers' Alliance got an idea that they would close up the resorts where the soldiers congregated, which they succeeded in doing, and venereal disease increased very rapidly. A year after that I was sent with the Fifth Cavalry about twenty or thirty miles from Honolulu, and we still had a great deal of venereal disease. I prevailed on the commanding officer to issue an order, which the major says now is a part of the army regulations, court-martialing men who neglected their duty in this respect. We used a 1:3,000 potassium permanganate solution and a 33 per cent. calomel ointment, and venereal disease diminished by 85 per cent. Prophylaxis, if insisted on by the regimental surgeons and in the regimental infirmaries, will do the most good in stamping out venereal disease among the soldiers.

Dr. V. G. Vecki, San Francisco: Formerly the words "syphilis" and "gonorrhea" were tabu in public, and anything in the way of a prophylactic was not considered. Now even cities are going to establish prophylactic stations; at least in California. Colonel Maus, of the United States Army, who really is the pioneer of prophylaxis in the Army, has finally gotten the power to do things. Formerly when the physicians of the country advanced something that would be of benefit to the public there was no power behind their recommendations. The people would not follow; but now when the power of the United States Army stands behind the use of prophylactic measures and behind the enforcement of the rules to prevent the spread of venereal diseases, something is going to be accomplished.

I am, and always have been, a great stickler for personal freedom. I certainly would not approve of certain measures which are being taken in California in ordinary times; but the main thing now is to win the war. All other interests must be put in the background; and as we cannot win the war with a diseased Army, we have to do all we possibly can to keep disease out of the Army. We must not, however, be carried away by any kind of a delusion that we are really diminishing prostitution, because that is not true. We hear all kinds of societies report that there is no more prostitution—because they do not see any more of it, and they do not know anything about it. Prostitution is only taking another form. It seems that there is some kind of an evolution. No man is satisfied to go to a common house of prostitution; he wants to go somewhere to some sort of social gathering, and very frequently prostitution is to be found there at present.

The only hope we have is in this personal prophylaxis, and you cannot expect a man to use it unless he knows that it is absolutely necessary and that it is good for him, so that we must give him instructions at the same time that we furnish him with the prophylactic. Who is going to instruct the man? The medical officer in the regiment ought to take a personal interest in the men and take them into his confidence, explaining to them in a way that they will know that these measures are taken for their personal benefit. Such instruction is badly needed.

Dr. A. L. Wolbarst, New York: A few years ago a man would not have dared to say the things we are saying today about prophylaxis; he would have been accused of "compromising with vice." That was the expression that was used against those who advocated prophylaxis five or ten years ago. Today Dr. Belfield struck the nail on the head when he said if the soldier will not come to the station to get prophylaxis, the thing to do is to bring prophylaxis to him. One of the most important elements of prophylaxis has been overlooked in this discussion. I read somewhere that one of the foreign governments has adopted a prophylactic package which contains not only the ordinary prophylactic but also one or two rubber condoms. That is the most efficient prophylactic, as nearly as we can give it to the men. If we could induce every soldier to use a condom we would thereby have brought prophylaxis to him in the best possible manner. There is nothing better that I know of for prophylaxis than a rubber condom. If we want to protect these men from getting disease, let us go the limit. We ought to drop this prudishness that exists about the condom—this idea of hiding our heads in the sand and saying it does not exist because we are ashamed of it. If prophylaxis is the thing aimed at, give them prophylaxis; protect these men by the best means that we have, even if that involves the use of a condom in addition to the other things. Then when these men come back to the station give them all the prophylactic treatment you can give them.

Dr. John R. Caulk, St. Louis: The two great problems in venereal diseases are, first, prophylaxis with which we should all agree, and second, in the Army to institute treatment which will get the men back to duty in the quickest possible time. As to Major Thompson's paper, I have just one suggestion, and that is with reference to acute posterior involvements, particularly acute epididymitis, for which we have for some time been using small injections of horse serum, with the most remarkable effects. In every case improvement has followed. In twenty-four hours the worst cases subside under the influence of this treatment, and in two or three days the patients are up and about; we do not have to keep them off duty. Some of the other cases that we followed show practically no scar in the epididymis. We first started with 10 c.c. of horse serum injected into the muscular tissues of the buttocks; but we found that 1 c.c. or 2 c.c. does just as well. I would suggest to Major Thompson to try it in the Army. I think he will get some very encouraging results.

Dr. A. E. Goldstein, Baltimore: It was stated that the best results were obtained with the prophylactic treatment when used inside of one hour after exposure. Camp Meade, Md., is supposed to be one of the best camps in the country. The length of time that it takes for a train to get from Baltimore or the nearest place in which the soldiers make visits is about an hour and a half; therefore, if a man returns from Baltimore to Camp Meade for his treatment he would necessarily not receive the full benefit of the treatment; so that in Baltimore they are establishing stations where the men can receive treatment, and good results are being obtained. The men on exposure immediately report to one of these stations, and within half an hour or forty-five minutes receive the prophylactic injection.

Regarding Dr. Caulk's mention of horse serum, we have not had any wonderful results with it, but have had good results with antimeningococcic serum. The only reason that these results have not been published is that we did not want to publish them until after trying them out thoroughly.

Dr. W. J. Wallace, Oklahoma City: I have never tried treating acute epididymitis by the use of horse serum. The treatment I have been using for years has been to incise over the most prominent part of the testicle through the layers of the tunica vaginalis and liberating the contents, which is usually a small hydrocele of the epididymis, break up adhesions and push the testicle through the incision of the tunica vaginalis, replacing it and closing the opening.

In this way, I get rid of all fluids and it prevents a recurrence. The patients generally make a rapid recovery. I perform this operation invariably in all of my private cases when I can persuade them to go to a hospital and it is the rule to perform this on all of my clinical cases at our dispensary.

Dr. A. E. Mowry, Chicago: Many men have venereal disease and will not report it because of the fact that they have to make their case public property in order to obtain treatment. If the doctor could treat the patient privately, many more of the men would take the treatment and try their very best to get rid of a disease which in the end gives them a great deal of trouble. I understand that this is being advised in the French army.

I would like to ask Dr. Thompson whether he advocates using the soluble mercurials, in big doses, two or three times a week, for the treatment of syphilis, rather than the insoluble salts. In my own experience the use of soluble mercurials in big doses has proved very much more efficacious in eradicating syphilis permanently and quickly than the insoluble salts.

Dr. W. G. Schulte, Salt Lake City: In regard to the use of mercury in the treatment of syphilis, I would like to know whether the major has used bichlorid in the salt solution intravenously? It has given good results in those cases where urgent treatment was necessary, using first one-thirtieth of a grain and increasing to one-tenth of a grain daily. In epididymitis we have found vaso puncture with the hypodermic needle good practice. The inflammation has subsided in forty-eight hours, without any horse serum.

Dr. William C. Quimby, Boston: The problem of venereal prophylaxis in the Army is a part only, although a large part, of the problem of venereal prophylaxis in civil life. The ratio of infection in civil communities of large population is infinitely greater than that in the Army. The Army, however, must draw its personnel from civil life in large measure at present; therefore, not only should we as physicians do our utmost to promote all prophylactic measures and instruction in sex hygiene in the Army, but we should also do it in civil life. Following, in a measure, the admirable steps taken by California, the state board of health of Massachusetts has secured legislation making venereal disease reportable. Of course, in the beginning such a measure has to go slowly, because of the fact that the physicians throughout the state have to form the habit of reporting. It will thus take several months, or maybe a year, before the statistics will be reliable. I think venereal disease has been reportable in Massachusetts for about three months; and even in this short time Dr. Kelley of the state board of health says that it already ranks third in the list of diseases; second only to tuberculosis and measles. This shows what an enormous incidence there is in civil life of gonorrhea and syphilis. The Massachusetts Medical Society has formed a committee to study the subject and endeavor in any way possible to aid not only the state board of health but also those members of the Army who have been delegated to work on sex hygiene questions. We have found in Massachusetts, and certainly it must exist in other states as well, that one condition which needs immediate and strenuous correction is the unwillingness of large hospitals, speaking broadly, to admit cases of venereal disease to their wards. This attitude has obtained not only in small private hospitals which are run for personal profit, but in the civic hospitals as well. We hope through the medical profession, in time, to get all the hospitals converted, so that they will be ashamed to show any unwillingness to admit a case of acute venereal disease.

In regard to combating venereal disease in civil life, insist on securing, if possible, from each patient the name of their partner, of whichever sex. In that way a great deal will be accomplished. I think this should be insisted on more especially in regard to syphilis, probably, than in regard to gonorrhea. It is now being done by Dr. Morton Smith in his syphilis clinic at the Massachusetts General Hospital, and with very good results. The donor of the infection is immediately placed under medical supervision.

Dr. E. H. Martin, Hot Springs, Ark.: In the treatment of syphilis it does not seem reasonable to give every man, no matter what his weight, the same amount of arsphenamin. The object desired in giving arsphenamin is to get the blood to become a solution of a certain strength. A man weighing 240 pounds, without extra fat, will have twice as much blood as one weighing 120 pounds. In the case of the man of 120 pounds, it is evident that he should receive only half the amount given to the larger man. I have found that one decigram of arsphenamin to every 20 pounds, approximately, of the patient's weight is always efficacious in secondary cases. Many heavy patients require eight decigrams and some a gram. I have given as much as twelve decigrams at a dose to a very large patient. I have found no harm to result in the way of increased toxicity in giving larger doses. The danger is in giving many doses rather than in giving large doses. All of the complications which have occurred in my experience followed a series of doses usually, sometimes after the second dose; but the rash and dermatitis that give so much trouble nearly always appear after a number of doses and often after small doses. In giving these large doses I find it entirely unnecessary to use mercury, which under the plan advocated by Dr Thompson nullifies the value of the subsequent Wassermann, if there is anything in the theory that mercury will sometimes bring about a negative Wassermann before a cure is established. If you bring about a negative Wassermann by adding mercury to the treatment, you do not know whether the arsphenamin has cured the patient or not; but after using large doses only until you have a negative Wassermann you may feel sure of a cure, especially if we accept the theory of the provocative effect of the drug.

Dr. Charles M. Harpster, Toledo, Ohio: In our city we were confronted with the venereal problem by a number of the large corporations. We were able to induce a number of them to permit of making a venereal survey. My office within the past year has examined over 3,000 men working for the large corporations who were sent to us for these examinations. This should be promulgated and put forward as a necessary war measure by every physician. We can then isolate those individuals that are infected, and give them proper venereal treatment.

Dr. Lawrence T. Price, Richmond, Va.: I would like to ask the major what regulations apply to the officers at Camp Beauregard on this subject. I understand that there are no regulations or exactions, and that it is left to them to abstain from sexual relations because they are officers. At Richmond the urologist sees as private patients a great many cases of venereal diseases affecting officers. These men transmit infection in the same proportion as enlisted men. The venereal situation has been very difficult for us to handle until recently. At the session of our legislature during the past winter, at least seven bills were introduced attempting to cover the problem; none of them passed.

The commonwealth's attorney of Newport News discovered an old law that stated that any person suspected of being immoral or venereally infected could be arrested and subjected to examination under the charge of being a "person of ill fame," and the disposal of the individual is being handled according to the facilities of the local health commissioners in the several cities. Since the meeting in Chicago, we have put the above into effect and I have treated over fifty cases without legal complications, and double this number of arrests have been made.

Dr. Granville MacGowan, Los Angeles: I am the executive officer of a medical advisory board which I think has more trouble on its hands than any other medical advisory board of the country. We have a million and a quarter of individuals to look after. The regulations in the selective service in regard to syphilis and gonorrhea are rather peculiar. Syphilis is no bar to service in the Army unless that syphilis has affected the nervous system, or unless there is deformity. If you were to attempt to get an army without having men who had gonorrhea you would not have an army. My belief is that not 10 per cent. of the men who reach the age of 30 have not had gonorrhea. I mean to say that 90 per cent. of the men who have reached the age of 30 either have had it or have it. My experience may be a little different from that of other people, but I believe that one man out of every five sitting in this room is a syphilitic—that is, 20 per cent.

As to the question of the measures which we took in the state of California toward keeping down venereal diseases, it is true enough that all of these measures are impossible of enforcement when this condition exists in society. In this last year I have seen three good men receive gonorrhea for their wedding presents from the women who appeared to be of good social status and against whom nothing wrong was known; but on close investigation these women admitted that they had been infected either by a former husband or by some lover whom they had trusted. I know of two instances in which the daughters of rich men of high standing in church were allowed to marry men who had gonorrhea, because their fathers said: "These men will get over that gonorrhea. We had gonorrhea when we were boys, and it did not amount to anything." "It is not much worse," one of them said, "than a bad cold." These women were married, and they were supposed to have been separated from their husbands on account of that. One of them I know has since lost her ovaries.

The question has to be handled according to the way the majors and the colonels of the cantonments will work it out to the best possible advantage. We cannot send for the men who do not have gonorrhea.

DR. LOYD THOMPSON, Hot Springs, Ark.: Many things could be said in regard to prophylaxis in a camp of soldiers. Very frequently a man will go out and indulge in sexual intercourse, tonight, for instance, and he will not report for his prophylaxis when he comes back. Tomorrow he will get another pass and not indulge, but he will come back and take the prophylaxis thinking that "saves his face," and he will not be tried because he took the prophylaxis finally. We have no way of knowing whether he took it on the night that he indulged or at some subsequent time. That is one great difficulty we have to face.

Another point is this: We have found on questioning a large percentage of the men that we have not got accurate data. We found that they were careless when under the influence of liquor when they indulge in intercourse, and that it was on such occasions that they got infected. I do not pretend to be a prohibitionist, but I am here talking prohibition because it is our duty as physicians to combat disease not only from the venereal standpoint but from the standpoint of inefficiency in every way. A soldier is not a good soldier if he indulges in alcoholics. Eighty-five per cent. of the men who come to the clinics with venereal disease, new cases, have been using alcohol, enough to make them either hilarious or drunk.

Dr. Wolbarst mentioned the use of condoms. There was an article in the *Military Surgeon* last month advocating this same thing; but personally I do not believe it will work. It might help some, but it will not work with certainty in all cases, because many men will not use a condom. They will not use it when they are drunk. We expect to establish prophylactic stations in Alexandria as soon as I return—two perhaps. They will be under military control, and we hope that that is going to help some.

Dr Mowry talked about the administration of soluble salts of mercury. We only give insoluble salicylate there, because we cannot see our patients every day or even oftener than once a week. Practically all our syphilitics are on duty, and after the acute infectious stage has passed, which does not take very long, they are on duty, and we do not like to ask to have them come for treatment oftener than once a week. I have used an intravenous injection of mercury a great deal, and advocate it in certain cases. I use the benzoate more frequently than the bichlorid, however.

Dr. Price talked about the officers. I am not absolutely certain about the Army regulations in this matter, but I believe that they are the same for the officers as for the men; but they are winked at. In Camp Beauregard I have never known of an officer being tried for infractions of the rules in regard to venereal diseases. Quite a number of the officers there have come to be treated, the same as the privates do.

Dr. MacGowan said that he considered that 20 per cent. of all the men in this room were syphilitic at one time in their lives, and that 20 per cent. of men in all walks of life were. I can hardly agree with him on that. Certainly, from the number of Wassermann tests I have made I have not gotten such high figures as that, either in the Army or outside of it.

A SUCCESSFUL VENEREAL PREVENTION CAMPAIGN

W. RAY JONES, A.B., M.D.
Medical Inspector, City of Seattle Health Department
SEATTLE

The West recognized venereal diseases as a public health problem and undertook venereal prophylaxis when in the spring of 1913 Seattle established the first free municipal venereal clinic. It had as its chief the genito-urinary surgeon of the City Hospital, and was located in one of the outpatient rooms of the hospital. The object was to treat all indigent venereal patients, the surgeon donating the time and the city furnishing the equipment and medicine. Both male and female patients were treated, and any necessary surgical work was done in the hospital. That clinic is still running today.

In 1917, numerous individuals and various organizations tried to devise some means of decreasing venereal diseases among soldiers and sailors visiting our cities. Little came of this because of no two having the same idea, until the Committee on Venereal Prophylaxis of the state medical association, aided by public spirited persons, established two venereal prophylaxis stations. One was in Seattle and one in Tacoma. Here men exposed to venereal diseases could secure preventive treatment free of charge.

In October, 1917, the military authorities, in conformity with the national program for the prevention of venereal diseases, called the attention of Seattle to existing vice conditions. The result was the formulation of the plan outlined in the following paragraphs:

All persons known to the health department or police as prostitutes are arrested and held for a medical examination. When the police arrest these supposed prostitutes or pimps they put a disorderly person charge against each individual, and immediately turn the person over to the health department for examination as suspected of being infected with a communicable disease. This person is now under the jurisdiction of the health department and not admitted to bail until released as not infected. If on examination he or she is found to have a venereal disease, appropriate treatment is begun.

To be classed as diseased, the person must have a positive Wassermann reaction or a positive gonorrhea slide or clinical chancroids. Clinical evidence has to be confirmed by laboratory findings and weak positive Wassermann reactions by clinical evidence, and all evidence, both laboratory and clinical, whether diseased or not, confirmed by a second person. Physicians' health certificates are ignored, as in thirty cases collected, none were given after a thorough examination. If found not diseased, the person is returned to the police, and goes through the police court in the regular way on a disorderly person charge.

In an examination of 513 prostitutes and their associates by the Seattle Health Department, the findings of which are given in the accompanying table, 78 per cent. of the prostitutes were diseased, 60 per cent. having syphilis, 37 per cent. gonorrhea, and 17 per cent. both syphilis and gonorrhea, and among men associating with or living off prostitutes, 35 per cent. had syphilis, 27.5 per cent. gonorrhea, and 8.5 per cent. both.

All the diseased are regarded as actively or potentially infective. Women with syphilitic histories dating back twenty years were found with vulval mucous patches. One congenital syphilitic had a specific pharyngitis and chancroidal infection; no syphilitic, therefore, could be regarded as not likely to become infectious at any time. The policy is to regard all infected prostitutes and panders as a menace to the public health and treat them accordingly.

During the period between November 9 and July 1, the city treated in its quarantine stations 219 women with syphilis, releasing 120 with negative Wassermann reactions, and 126 women with gonorrhea, releasing 105 as cured. During the same time forty-five men with syphilis and thirty-four with gonorrhea were treated. The average number under treatment was about 150, though at one time 235 were interned. Forty-one women and twenty-one men were broken of the drug habit during treatment.

DISEASE RATING OF FIVE HUNDRED AND THIRTEEN PROSTITUTES AND THEIR ASSOCIATES*

	Women, Per Cent.	Men, Per Cent.
Syphilis	42.6	20.8
Gonorrhea	17.4	19.0
Syphilis and gonorrhea	17.0	8.5
Chancroids uncomplicated	0.2	0.1
No disease	22.0	47.0
Total diseased	78.0	53.0
Total syphilis	60.0	35.0
Total gonorrhea	37.0	26.4

* Findings in an examination of 384 women and 129 men by the Seattle Health Department between October, 1917, and July, 1918.

A syphilitic to be released must have a negative Wassermann reaction as well as no clinical signs, plus sufficient treatment to make a negative reaction of value. This treatment consists usually (according to the case) of weekly arsphenamin injections plus mixed treatment to saturation. Usually it required at least three months to secure a negative reaction. Wassermann tests for release are taken a week after the mercurial treatment has beeen suspended.

A gonorrheic must have three consecutive negative slides at least forty-eight hours apart, with all treatment suspended for at least forty-eight hours before taking the first. Men are also subjected to prostatic and seminal vesical massage.

The prime object is to prevent disease by removing the sources of infection, and then keep the girls from relaxing into former habits and becoming reinfected. All with homes are sent to their parents, and homes and occupations found for the others. All within a reasonable distance are required to report in person every two weeks after release.

Since the Seattle campaign began, the other cities of the state have taken up the work. The state board of health likewise has made venereal disease reportable. The requirements for release are probably the most stringent in the country, but public health demands the interning of all prostitutes and of men living off them as potential carriers of disease.

964 Empire Building.

DESCRIPTIVE PICTURE OF BERIBERI

NAGIB T. ABDOU, M.D.
Medical Officer, Health Officer's Department, Staten Island, N. Y.
ROSEBANK, N. Y.

In the latter part of April, 1918, a four masted schooner arrived in New York harbor from a port in British West Africa. The cargo consisted of logs, rubber and cocoa. Of the original crew of ten men, eight of whom were from Finland, the skipper and the cook being German-Americans, eight remained, and all except the skipper were suffering from beriberi. The trip consumed eighty-five days, during which hardships of all sorts were experienced. The remaining seven of the schooner's crew, victims of the original Oriental disease, were detected at quarantine by the boarding officer and brought to the Hoffman Island State Hospital for isolation and treatment. These patients landed in a somewhat prostrated condition, and one of them died the following day of acute dilatation and hypertrophy of the right ventricle, his case being an acute pernicious dry form of beriberi. In addition to the heart, the liver and kidneys were also affected.

CLINICAL OBSERVATIONS

Of the six patients, three were suffering from the wet or edematous form of beriberi. They complained of pain in the abdominal, epigastric, thoracic and lumbar regions, and had a general lassitude. The other three patients were suffering from the dry form of beriberi with similar symptoms. They had muscular atrophy; the calves of the legs became thin and flabby and the thigh emaciated with a sharp anterior edge of the tibia; their reflexes were somewhat altered and slow in response. One of these patients had as a complication scorbutus, and another, dermatitis exfoliativa. The patients had an evening temperature between 100 and 101 and a fraction, with an increased morning pulse rate to 105 while the temperature was normal. Now and then the stethoscope reflected an echo of a slight systolic murmur, which disappeared and reappeared until complete cure was effected. The laboratory findings were negative as to blood and feces, but urinalysis revealed albumin in small percentage in two cases and a trace of sugar in one case. Microscopically, epithelial casts of renal origin were detected. I noticed particularly some erythema on the hands and simple conjunctivitis in three patients out of the remaining six. The patients were as hungry as wolves, and food was given to them generously, their diet consisting of fresh fruits and vegetables, milk and fresh meat. They hated the sight of rice, and that Oriental dish was excluded, of course, from their bill of fare. They walked in the hall of the ward in a way that reminded the nurse of people dancing the "hesitation." They were constipated, and laxatives were frequently administered to them for relief.

In the line of drugs, cardiac stimulants, quinin and general tonics seemed favorable, and the careful and systematic administration of these brought the patients to complete recovery within thirty days of their admission into my service. The nurses in charge of the state ward took deep interest in the care of these beriberi patients, as it was their first experience in caring for the Japanese disease, and as they were preparing to join the Red Cross, there was a possibility of their being sent to tropical or semitropical countries for duty where they might have to deal again with beriberi. The patients, in their turn, were grateful, drew pictures of the schooner with a view of West Africa, and gave these to the nurses and dietitians as souvenirs before leaving Hoffman Island, which they did in the best spirits and physique.

CAUSATION AND INCIDENCE OF BERIBERI

Fraser and Stanton hold that the substance in unpolished rice that prevents beriberi is phosphorus pentoxid present to an extent of about 0.53 per cent., and reduced in polished rice to 0.26 per cent. Okata and Kokubo, Japanese army surgeons, reported the discovery of a diplococcus for beriberi, but inoculation experiments on monkeys have been negative. Hence the bacteriology of beriberi is still in the experimental stage. It is asserted also that feeding chickens and birds with spoiled rice has produced polyneuritis the same as in man. This will strengthen the theory of decomposed food and the pathogenic process of metabolism with the development of bacteria causing the kakke, or beriberi.

Beriberi is not limited to Oriental countries such as China, Japan, India and the Philippine Islands, but cases have been observed in Africa and in South America, especially in Brazil, and in the United States and Canada, England, Ireland and continental Europe. There are 50,000 cases yearly in Japan, and in the Philippine Islands there were 3,334 cases in 1910. The mortality in beriberi averages 33 per cent.

CONDITIONS ON THE TRIP FROM AFRICA

Before leaving the West African coast, the crew took fresh water from that land for drinking and cooking. Also they had provisions consisting of canned goods (meat and fish) and canned vegetables. The skipper shared the same bill of fare with his crew, and in addition he had whisky, pies and puddings, which he selfishly consumed in full view of the crew. Rain water was obtained during the trip, but the skipper kept it all for his own use, forcing the crew to drink only the water taken from the West African coast.

They alternated dishes with corry, rice and salt meat. Their chief mate left Assinie in a serious physical condition and died at sea a few days later. The donkeyman died also. Both sailors died evidently of beriberi. The seven other members of the crew became ill in the middle of their journey to New York with symptoms of swollen legs, pain in the epigastrium and in the chest and sides with a general "tired feeling." None except the captain brushed the teeth. They had for treatment cathartics and quinin, but the disease was slowly developing during the trip. After the swelling disappeared, numbness in the legs, paresthesia and coldness of the limbs ensued for several days preceding death.

CONCLUSION

I can agree with Braddon and Cooper that the continuous consumption of large quantities of carbohydrates, with their vitamin, causes beriberi, and that fresh vegetables and a mixed diet are evidently the best prophylactic measures.

Average Mental Ability.—Go into any court of law and hear a dozen witnesses describe the same event. You will become convinced that the average person cannot see nor hear more than one half straight, and cannot draw a conclusion from what he sees or hears more than 25 per cent. straight.—E. P. Lyon, *Texas State Journal of Medicine*.

Military Medicine and Surgery

IMPORTANCE OF BLOOD CULTURES IN PNEUMONIA

J. E. McCLELLAND, M.D. (Cleveland)
Captain, M. C., U. S. Army
CAMP BEAUREGARD, ALEXANDRIA, LA.

That many cases of pneumonia have an associated septicemia has long been known. The relation between the degree of septicemia and the severity of the disease has also been studied and appreciated. In fact, the statement has been made that "in the more severe cases a true septicemia is usually present, and this always occurs in the cases ending fatally." I have had no opportunity to make any review of the literature on this subject. I desire merely to give a brief report on the experience at this base hospital in order that the results may be compared with those obtained at the other camps and to urge the advisability and importance of taking blood cultures as a routine in all cases of pneumonia among the soldiers. The information thus gained is of great value in prognosis and serves as a helpful guide to the specific therapy in the Type I cases.

TABLE 1.—FREQUENCY OF POSITIVE BLOOD CULTURES IN THE VARIOUS TYPES OF PNEUMONIA

	No. Cases	Positive Blood Cultures	Per Cent.	Serum Treated	Empyema	Mortality	Per Cent.
Type I	13	6	46.1	12	1	1	7.7
Type II	4	1	25.0	0	0	1	25.0
Type III	1	0	0.0	0	0	0	0.0

During the months of May, June and July, blood cultures were taken as a routine in all cases diagnosed clinically as lobar pneumonia and in a few cases diagnosed as bronchopneumonia. These cultures were made in practically all instances within twenty-four hours after the patient was admitted to the pneumonia ward. If the admission culture proved negative and the condition of the patient continued satisfactory, the cultures were not repeated. On the other hand, if the admission culture was positive or the patient's condition continued to grow worse, the cultures were repeated as often as considered necessary. The greatest number taken in any one case was five.

In all cases the cultures were made by withdrawing from 15 to 20 c.c. of blood into a sterile Lüer-type syringe; from 10 to 15 c.c. were added to a flask containing from 100 to 150 c.c. of plain meat infusion broth; the remaining 5 c.c. were divided into 2 and 3 c.c. portions, each thoroughly mixed with 10 c.c. of plain melted agar, and plates were poured in the usual manner. All cultures were kept in the incubator for at least four or five days before being discarded as negative. In all positive cultures the organism was identified by staining and cultural characteristics, by tests for bile solubility, and if bile-soluble, the type of pneumococcus was determined by the reactions with immune serums.

Ninety-three cultures were taken on sixty-three different patients, and of these, eighteen, or 19.3 per cent., were positive. Thirteen of the sixty-three patients, or 20.6 per cent., had one or more positive cultures during the course of the disease. The frequency with which positive cultures were obtained in the various types of pneumococcus pneumonia, in hemolytic streptococcus pneumonia and in those in which the etiologic factor remained undetermined, is shown in Table 1. The increased tendency of the more virulent organisms (hemolytic streptococcus and pneumococcus Types I and II) to invade the blood stream is clearly apparent. Attention is also directed to the high mortality among these patients, with the exception of the Type I patients, who enjoyed the advantage of specific serum therapy. All the patients with hemolytic streptococcus infection developed empyema.

A list of the Type I pneumococcus cases is given in Table 2. These cases, as a rule, require much larger amounts of serum than those with negative cultures, and it is important that the serum treatment should be instituted early and pushed vigorously, especially during the first few days. The treatments should be repeated every six or eight hours, day and night, as long as the rectal temperature is 101 or higher. The rapid subsidence of the septicemia after one or two injections of serum is very striking. Even in the case of C. M., who died on the seventeenth day of the disease, the septicemia disappeared entirely after the second injection. The temperature, however, remained high, and he developed a double otitis media and finally died. The pneumonic process remained confined to the original involvement, namely, the left lower lobe, and the presence of empyema could never be demonstrated either by roentgen ray or needle, though the patient was explored repeatedly. A necropsy was not allowed. Death seemed to be due to the toxemia, which the serum, though administered generously (1,500 c.c.), did not seem to alleviate. It does seem, however, in this case, that the serum prolonged life. The temperature and septicemia curves of this case are shown in Chart 1. This case is very similar to one described by Cole,[1] in which a "persistent concentration of immune bodies could not be maintained in the patient's blood by the administration of immune serum." Of the six Type I cases with positive blood cultures, only one was fatal.

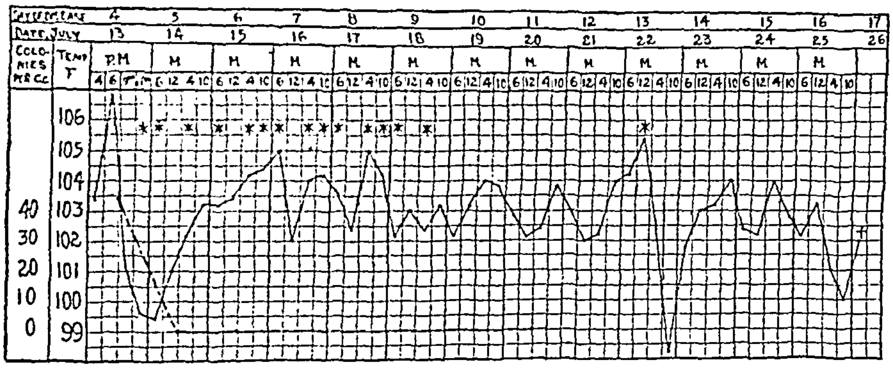

Chart 1.—Temperature and septicemia curves in a fatal case of Type I pneumonia. Note the critical fall in the septicemia curve after the first two injections of specific serum. Solid line, temperature; broken line, septicemia; *, injection of 100 c.c. of serum; †, death of patient.

In Type II cases a septicemia is always of grave import. In the four cases listed in Table 2 septicemia was demonstrated in only one. This patient had a very heavy infection, approximately 100 colonies per cubic centimeter, and died ten hours after the blood culture was obtained.

TABLE 2.—RAPID DISAPPEARANCE OF THE SEPTICEMIA IN TYPE I CASES THAT ARE SERUM TREATED

	4	0	300	No	Recovery
O. M.	4	44			
	5	0			
	6	0			
	11	0	1,500	No	Died

We had only one Type III case during this time. The blood culture on admission was negative, and the disease ran a very mild course.

Of the twenty-four IV cases, a positive blood culture was obtained in only one. Clinically this patient showed consolidation of the entire left lung. He was admitted to the pneumonia ward on the sixth day of the disease, and a blood culture was made the same day. It showed thirty-one colonies per cubic centimeter. A second culture was made two days later, July 12, and showed a slight increase to thirty-four colonies per cubic centimeter. July 13, a third culture was made and showed a reduction to eleven colonies per cubic centimeter; July 14, there were only four colonies per cubic centimeter, and, July 15, the septicemia had entirely disappeared. The clinical course paralleled the septicemia, but even during the height of the disease the patient appeared quite comfortable, and at no time was his condition considered critical. As soon as the blood became sterile, the patient entered on a rapid and uninterrupted convalescence. This case

1. Cole, Rufus: Jour. Exper. Med., 1917, **26**, 465.

demonstrates that a patient may have a relatively severe septicemia with an organism of low virulence and still not be very sick. The proof that we were dealing with a Type IV pneumococcus was established by injecting several cubic centimeters of one of the blood cultures in broth intraperitoneally into a white rat. The rat died in less than sixteen hours, and at necropsy showed a severe peritonitis, the exudate containing large numbers of gram-positive encapsulated diplococci which were bile soluble but did not react specifically with Type I, II or III serum. A second rat was injected intraperitoneally with 2 c.c. of sputum emulsion from the same patient. This rat also died over night. At necropsy an identical organism was recovered from both peritoneal exudate and heart's blood. The temperature and blood culture curves in this case are shown in Chart 2.

There were twelve cases in which the etiologic factor was undetermined. None of these patients had a positive blood culture, and all recovered.

A list of the hemolytic streptococcus cases with positive blood cultures is given in Table 3. There were five of these cases; all were complicated by empyema, and four of the patients died. This shows the gravity of septicemia in these cases. A. Y., who recovered, had a negative culture one hour before his operation for empyema. Another culture taken the following morning was negative in the plates but positive in the broth. Cultures were repeated twenty-four hours later and were entirely negative. This case illustrates that a patient may have a slight hemolytic streptococcus septicemia and still recover. The supposition that a relatively small number of organisms gained access to the blood stream through the operative wounds seems reasonable. The patient apparently developed a rapid immunity and overcame the septicemia before it gained much headway.

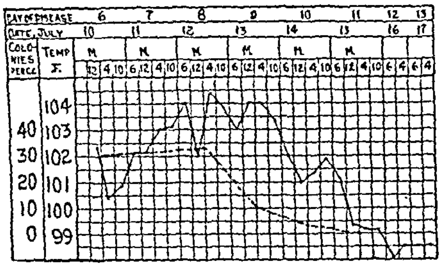

Chart 2.—Temperature and septicemia curves in a case of Type IV pneumonia in which the patient recovered. Note the initial rise followed by the gradual fall in the septicemia curve, and the parallelism of the curves.

In direct contrast to the foregoing case is that of M. A. This patient had a negative blood culture antemortem, and a second blood culture taken eight hours postmortem was negative both in the broth and in the plates. The necropsy disclosed a very extensive bronchopneumonia involving most of the right lung and part of the lower left lobe. In addition there was an empyema on the right side which had been diagnosed antemortem. This patient evidently died from a severe toxemia rather than from a septicemia. All the other hemolytic streptococcus patients with negative blood cultures recovered.

SUMMARY AND CONCLUSIONS

1. Blood cultures in pneumonia are valuable from the standpoint of prognosis and as a guide in the serum therapy of the Type I cases.

2. Septicemia is more common with the more virulent strains of pneumococcus and with *Streptococcus hemolyticus.*

3. Type I pneumococcus septicemia responds very promptly to immune serum treatment.

4. A moderately severe Type IV pneumococcus septicemia may be quickly recovered from.

5. The mortality in hemolytic streptococcus septicemia is very high, but one case is reported in which the patient had a slight transient septicemia and recovered.

SELECTIVE ACTION OF DILUTE SODIUM HYDROXID ON CERTAIN RACES OF THE PNEUMOCOCCUS *

ANDREW WATSON SELLARDS, M.D. (Boston)
Major, M. C., U. S. Army
CAMP DEVENS, AYER, MASS.

It was demonstrated by Neufeld in 1900 that pneumococci, in contrast to many species of bacteria, are readily soluble in bile. Neufeld[1] stated, on incomplete evidence, that the bile salt is the constituent of bile which is responsible for the lytic action on the pneumococcus. This statement found ready acceptance, very possibly because of the well-known action of bile salts in dissolving red corpuscles.[2] However, in the routine tests for the differentiation of pneumococci and streptococci, a solution of bile salts dissolves the pneumococcus so feebly and so irregularly that whole bile is used in preference to the purified salts. The concentration of bile salts in bile varies widely, but as a rule it is less than 1 per cent.; a 10 per cent. solution of bile salt, however, is recommended if these salts are substituted for bile in the solubility tests.[3] One part of this 10 per cent. solution is added to nine parts of a broth culture of the organisms to be tested. Rosenow[4] mentions the solution of pneumococci in 0.5 per cent. bile salt. Such behavior is exceptional; with a 2 per cent. solution of sodium cholate, Cole[5] found that many typical strains dissolved incompletely or not at all.

It seems probable that other constituents of bile play an important rôle in the solution of the pneumococci. The pigments merit consideration because of their cytolytic action in the presence of light (photodynamic action). Some bactericidal but no appreciable bacteriolytic action could be demonstrated with pneumococci under the following conditions:

One per cent. of bilirubin was dissolved in salt solution with the aid of a little alkali. One part of this was mixed with nine parts of a suspension of pneumococci in salt solution. Strains belonging both to Group 1 and Group 2 were tested. The mixture was exposed in thin walled test tubes of ordinary glass, 1 cm. in diameter, to direct sunlight for five hours. The bile pigment became much lighter in color but this mixture remained turbid and stained preparations showed numerous pneumococci. Therefore it does not seem that the bile pigments alone could play any important part in the solution of pneumococci by bile under ordinary routine conditions.

---

* The observations reported in this paper were carried out at the Base Hospital, Camp Dodge, Iowa, and at the Pathological Laboratory of the Johns Hopkins Medical School, Baltimore.

[1] Neufeld: Ztschr. f. Hyg., 1900, **34**, 454.

[2] The term "bile salt" ordinarily indicates the salt of cholic acid conjugated either with glychocholate or taurocholate. Since the cholate radical is the active portion of the molecule, sodium cholate is sometimes employed instead of the conjugated products.

The alkaline reaction of bile deserves attention since neither the pigments nor the bile salts can remain in solution in a distinctly acid medium. A specimen of calf's bile after autoclaving and filtration was titrated roughly against litmus paper; its alkali content corresponded roughly to a hundredth normal solution. The importance of avoiding an acid reaction in carrying out the bile solubility test was noted by Cole,[5] who advises a slightly alkaline medium composed of primary and secondary phosphates. On using a stronger alkali, however, it will be seen from the following data that certain strains of pneumococci dissolve rather readily in dilute sodium hydroxid alone without the aid of bile. For example, one strain (Group 2) dissolved readily in twenty-fifth normal hydroxid. Another culture of the same strain after incubation for twenty-four hours at 37 C. was allowed to stand for one week at room temperature. The washed sediment of bacteria then dissolved in remarkably high dilutions of sodium hydroxid. One part of a very cloudy suspension of the washed bacteria cleared immediately when mixed with an equal part of a five hundredth normal solution. Almost complete solution took place with thousandth normal sodium hydroxid, a dilution that failed to react with litmus paper. This high degree of solubility was not found frequently, however, and it occurred only in the older cultures. Fresh cultures of several strains were tested for their solubility (1) in bile, (2) in sodium taurocholate and (3) in sodium hydroxid.

In order to secure a good suspension of pneumococci, inoculations were made from blood agar slants to glucose meat infusion broth. After eighteen hours' growth the broth cultures were centrifugalized, the sediment washed once with physiological sodium chlorid solution, and then suspended in saline. This suspension was neutral to litmus.

Bile of young calves was autoclaved. Before use the clear supernatant fluid was filtered off from the resulting precipitate. Sodium taurocholate was used in 2 per cent. solution in physiological sodium chlorid solution. This solution was slightly turbid and distinctly acid, but it cleared promptly on neutralization to litmus with sodium hydroxid. For the tests with sodium hydroxid, a fifth normal solution was used, and strains readily soluble in this were tested in more dilute solution. One part of the suspension of pneumococci was mixed with one part of each of the preceding solutions, giving, therefore, in the final preparations, a concentration of 1 per cent. sodium taurocholate and tenth normal sodium hydroxid. Solution often occurred immediately, though to secure constant results the mixtures were incubated for one hour at 37 C. before the final readings were taken. The results[6] are given in Table 1.

From the data in Table 1 it is seen that bile is a much better solvent for pneumococci than either sodium hydroxid (fifth normal) or sodium taurocholate (2 per cent.). In the cultivation of the pneumococci it has long been recognized that the development of acid in the medium inhibits growth; it was not evident, however, that some races are also very susceptible to alkali. The solubility in sodium hydroxid varies considerably even in the same immunologic group. It is unfortunate that a larger number of typical races were not available for study. The testing of a large number of strains of pneumococci might reveal some correlation between solubility in alkali and other characteristics, such as pathogenesis and virulence. In Table 1 it will be noted that a conspicuously large proportion of the atypical Group II strains are soluble in bile salt but not in sodium hydroxid. Of the strains in the borderline group between pneumococci and streptococci, it is noteworthy that none of these dissolve readily in either bile salt or sodium hydroxid. It would be impossible, however, to attempt any generalizations from a small number of strains.

In contrast to this ready solubility of some of the strains of pneumococci, it was found that ten strains of hemolytic streptococci isolated at Camp Dodge, Iowa, showed no evidence of any solubility with fifth normal sodium hydroxid.

TABLE 2.—EFFECT OF AGE OF CULTURE ON SOLUBILITY OF PNEUMOCOCCI *

Culture	Strength of Sodium Hydroxid N/5	N/10	N/50	N/100
Strain 1, 18 hours' growth	C	C	C	P
Strain 1, 12 days' growth	C	C	C	AC
Strain 18, 18 hours' growth	C	AC	0	0
Strain 18, 12 days' growth	C	C	C	AC
Strain 23, 18 hours' growth	0	0	0	0
Strain 23, 12 days' growth	0	0	0	0
Strain 24, 18 hours' growth	0	0		
Strain 24, 12 days' growth	C	C	C	C

* C, complete solution; AC, almost complete solution; P, partial solution; 0, no solution.

Some evidence was obtained in regard to the effect of the age of cultures on solubility of pneumococci in alkali. Four of the strains recorded in Table 1 were grown in glucose broth for twelve days and then tested according to the preceding technic. The results are given in Table 2.

---

[6] These strains were collected and studied by Dr. Mildred Clough. I am much indebted to her for the use of this material and for her kind cooperation.

In Table 2 it is seen that, in the case of Strains 18 and 24, the older cultures were markedly more soluble than fresh ones. Strain 23 is of especial interest since neither the old nor the young cultures were soluble. Dr. Clough considers that this strain should probably be classed with the streptococci rather than with the pneumococci.

From the preceding data it is evident that, in testing the solution of pneumococci in bile, certain factors most be controlled in order to secure constant results; special attention should be given to the age of the culture and to the reaction of the medium.

Neufeld considers that the bile salts act specifically on pneumococci and thus resemble the immune bodies, in contrast to the chemical disinfectants, which act more or less alike on all bacteria. The solubility of certain strains of pneumococci in sodium hydroxid furnishes an example of a relatively high degree of specificity in a simple chemical substance.

In conclusion, it should be noted that the solvent action of bile on pneumococci is not easily explained. Moreover, the process may vary with the individual strains of pneumococci; this is indicated by the rather wide variation that different strains show in their solubility in bile salts and in alkali. The various constituents of bile, when isolated and tested separately, are less effective than the whole bile. An analogous situation exists in the effect of bile on certain ferments. A thorough explanation of the action of bile on pneumococci would be of service in any attempt at the therapeutic application of bile products in pneumococcal infections.

SUMMARY

The effect of bile salts does not adequately explain the solvent action of whole bile on pneumococci; in searching for other active constituents, no evidence was obtained of bacteriolytic action by bile pigments on pneumococci. Alkali in dilute solution (hundredth normal) was found to dissolve certain strains of typical pneumococci. A sufficient number of strains have not yet been tested for determining the exact relationship between solubility in dilute alkali and other characteristics of the pneumococcus, such as virulence and the immunologic groupings. Ten strains of hemolytic streptococci were tested and none were soluble in sodium hydroxid (fifth normal). In testing the solubility of pneumococci in bile, the age of the culture and the reaction of the medium are important factors. The explanation of this solvent action is by no means complete. It is quite possible that the process varies with the different strains of pneumococci; more complete data would be of value in any attempt at the therapeutic utilization of bile products in pneumococcal infections.

Utilizing Birth Records.—In the year 1916 over 172,000 searches were made of the records of births, deaths and marriages on file in the department of health in the city of New York, almost 100,000 being free searches of birth records for admission into school, obtainment of employment certificates and for granting of money to widowed mothers. Almost 20,000 paid searches were made of the records of births for various purposes. The uses to which the transcripts of the records of births were put were many, such as to obtain passports, to prove kinship in litigation of wills, etc., to obtain a license to marry in those cases in which the city clerk refuses to grant marriage licenses unless age is proved, to establish exact date of birth for use in criminal court, to obtain deposits in savings banks, etc.—W. H. Guylfoy, M.D., Registrar.

CONVOYS AND THEIR CARE

THE ADMITTING SECTION OF AN EVACUATION HOSPITAL DURING COMBAT

GEORGE de TARNOWSKY, M.D. (Chicago)
Major, M. C., U. S. Army
A. E. F., France

While the admission of patients is normally included among the duties of the officer of the day, in actual warfare it has been found necessary to appoint a special admitting officer for this extremely important and difficult task. The term "difficult" must be qualified, in order to make its meaning clear. If, by admission, we merely understand the "taking up" of the wounded by means of their field medical cards, the filling out of data on their clinical records — Form 55 A — and assigning them by rotation to their respective wards, it stands to reason that a squad of orderlies whose handwriting is legible, under charge of a junior officer, will meet such demands satisfactorily. If, on the contrary, and as should be the case, the admitting officer must, in addition to supervision of paper work, personally act as sorting officer (*triage* of the French), then his duties immediately assume great importance. Not only should he be a surgeon of quick and mature judgment, but he must also constantly have in mind, or on paper: (*a*) the relative technical value of the different surgical teams in the hospital; (*b*) the special surgical teams on duty (thoracic, neurosurgical, etc.); (*c*) the hours of the different surgical shifts, and (*d*) the available beds in each surgical service.

PERSONNEL AND DUTIES OF THE ADMITTING SQUAD

One sergeant and from four to six privates of the Hospital Corps, selected for their clerical qualifications, will suffice for ordinary convoys; this number may have to be doubled or trebled if the casualties are pouring in by the hundred. Rapidity and accuracy are both essential; ambulances must be promptly discharged and blankets, pillows and stretchers returned in order not to hinder transportation problems. A varying number of stretcher bearers must also be assigned for duty during the emergency, as well as a squad of orderlies to wrap up and make out receipts for clothing.

The hospital organization must be made elastic enough to meet all contingencies, rigidity must give way to flexibility, if one does not wish to see the evacuation hospital grounds littered up with a tangled mass of ambulances, stretchers and walking wounded—precious hours wasted because sudden shiftings of duties and details have not been foreseen and worked out.

Each admitting clerk should possess a quick, legible handwriting, together with a general knowledge of wound nomenclature and accepted abbreviations.

The patients classed as walking cases line up in front of the clerks' table, give up their field medical cards, receive a ward ticket and pass on rapidly to the buffet.

Stretchers are laid in rows in the admitting tent and the clerks pass rapidly from one to the other, recording all necessary data in duplicate, for all urgent cases. As fast as the duplicate clinical record is filled out, with the ward number recorded on it, the stretcher bearers carry each patient to the receiving ward, returning litter, pillow and blankets to the ambulance waiting outside.

The admitting officer, from an examination of the general appearance of a given patient, the pulse rate and written indications on the field medical card, decides as to his disposal. When in doubt, he should wait until the patient is in bed in the receiving ward, in order to make a thorough examination before coming to any conclusion.

In order to have at all times an accurate list of available beds, a register book is kept by the admitting sergeant. Based on the ward roster, taken after an evacuation has occurred, if any, a daily sheet is made out on which are recorded: (*a*) ward number, and (*b*) vacant beds in each ward, each vacancy being indicated by a vertical line *opposite* the ward number, for example: Aug. 20, W. I., 9 | | | | | | | | |

Whenever a patient is assigned to a ward, one of the vertical lines is crossed, so that the clerk—subject to orders—maintains an equable balance among the different services. At the bottom of the daily sheet are recorded the total number of vacant beds in the hospital, *total number of patients in the hospital, and* total number of admissions since the opening of the hospital.

Fig. 1.—American Red Cross Military Hospital No. 5: panorama of hospital tents, all belonging to the same unit.

A weekly list of convoys is also made up, with the total number received each day from 7 a. m. to 7 p. m. and from 7 p. m. to 7 a. m. At the end of each month, the total number of admissions during that period is also recorded. The details of this system were all worked out by Capt. J. D. Bruce, M. C., admitting officer and director of surgical material at the American Red Cross Military Hospital No. 5; the entire system has been so generally successful and has proved to be such an invaluable time saver that it has seemed worth while to describe all of its minutiae. The great problem in an evacuation hospital is to operate properly and rapidly on a large number of patients in a short space of time—the shorter, the better for each patient. I am sure that every surgeon will agree with me that much time is needlessly wasted in the operating room, waiting for patients. If one represents as 100 the total expenditure of time in a given surgical case—from the time the patient arrives in the ward until he returns thereto from the operating room—this number can ordinarily be thus subdivided:

Undressing and cleansing of patient	30
Preparation of operative field in ward	10
Waiting for turn in roentgen-ray room and fluoroscopy	10
Anesthetizing patient and placing him on table	10
Operation	20
Dressing, bandaging, immobilization and removal of patient from operating room	20
Total	100

A properly organized admitting tent and competent director of surgical material will easily quadruple the operative output of a surgical team—an all important item during a heavy battle.

SORTING (TRIAGE) OF THE WOUNDED

The rough-and-ready division of wounded from the regimental aid post or field hospital into walking and stretcher cases has only a relative bearing on the severity of the wounds or the urgency of their radical treatment. Many patients classed as "walking" cases have collapsed from internal hemorrhage or gas gangrene on admission or shortly afterward; many classed as "*stretcher*" *cases have turned* out to have only a superficial flesh wound or extra-articular contusion. This is not intended as a criticism of the dressing station or field hospital; to make more than a snap shot diagnosis, when a steady stream of wounded men is pouring into a dugout or tent, is out of the question. The first complete diagnosis must be made in the evacuation hospital, and on the admitting officer falls this heavy burden. With a sudden convoy of three or four hundred casualties arriving within a few hours, and from five to ten surgical teams in the operating rooms, it stands to reason that some of the wounded will have to wait several hours before their turn comes. The admitting officer must decide on the order of precedence. When a big battle is on there can never be enough surgical teams in an evacuation hospital to operate on all patients within twelve hours after admission. Fortunately for our wounded, the percentage requiring immediate limb or life-saving intervention is relatively small—probably not more than 20 per cent. These are the wounded that must reach the operating room immediately, regardless of the order of their admission or of the surgical service to which they are assigned.

Theoretically, and during relatively calm periods, each surgical team should examine its patients before they are admitted to the operating room; practically, this is not possible during an active "show." Each team is operating, dressing patients and snatching a few hours out of the twenty-four for meals and sleep. On the admitting officer must devolve a diagnosis of the relative urgency of each case, its confirmation by the fluoroscope (localization of foreign bodies, fractures) and the surgical preparation of the wound area by the ward orderlies and nurses. When in doubt as to the severity of a given case, etc., he can and should call in the aid of the consulting surgeon or chief of surgical services. While convoy follows convoy, and the operating teams are straining every ounce of strength in order to meet the demands placed on them, all surgical cases must be pooled, the only exception to this rule being those wounds demanding special technic in their treatment; the latter alone should be reserved for operation by teams previously trained and selected for that purpose. Such teams must be ready at all hours to operate when called on to do so.

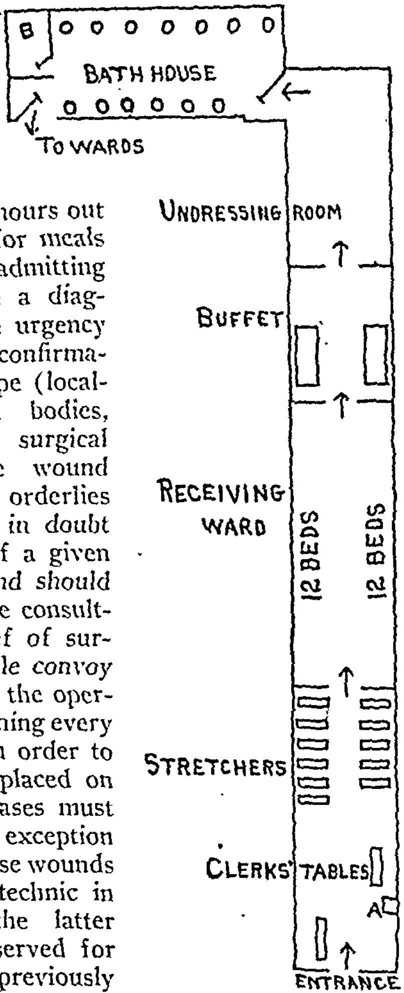

Fig. 2.—General plan of admitting section: *A*, table at which money, etc., may be deposited; *B*, clothing, pajamas, etc.

ADMITTING OFFICER AND *DIRECTOR OF SURGICAL MATERIAL*

Having supervised the admission of a convoy, and divided the cases into medical, slightly wounded and severely wounded, the admitting officer should devote his attention to the latter cases.

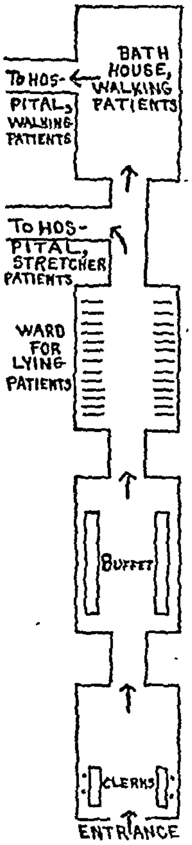
From the admitting tent all severely wounded pass directly into the receiving ward, where they are placed on specially prepared beds, undressed, deloused and washed by orderlies and nurses. In order to avoid contamination by lice, etc., the bed is first made up in the ordinary manner, and a sheet placed over the blanket. The patient is laid on the sheet covered by an extra blanket or two, undressed and cleansed *without* exposure of more of his body than is absolutely necessary. When he is ready for his pajamas, the extra top sheet and blankets are rolled away from under him and he is slipped under the regular coverings. The extra top sheet and blankets are taken to the delousing station and sterilized. Light diet is furnished from the buffet and given to all patients excepting those presenting intra-abdominal lesions or suffering from concussion or coma.

In shock cases, if very severe, the patients are not undressed at all, but heat is applied around their bodies, hot drinks are given them or they are transfused, either in the same ward or in a special room containing separate heat chambers (*cellules chauffantes*).

Having sorted the severely wounded into urgent surgical, observation and borderline cases, the admitting officer directs the former, in proper order, to the roentgen-ray room, where they are fluoroscoped, all fractures recorded and foreign bodies localized. All severe observation and borderline cases are assigned and transferred to the different surgical wards, special or general, where they are examined a second time by the chief of the surgical team and booked for operation during that team's shift. Should an operative emergency develop among these cases, the patient is immediately ordered to the operating room and operated on by one of the teams on shift at the time.

In order that all available data may reach the operating surgeon before or while the patient is being anesthetized, a duplicate clinical record of all severe cases is made out in the admitting tent. One copy goes to the registrar's office, in order not to delay the daily sick and wounded report, and the other, with the field card and roentgen findings, accompanies the patient to the operating room. The clinical records and field cards of the slightly wounded and medical cases are not made out in duplicate, both documents going from the admitting tent to the registrar's office, whence they are returned to the proper wards. Should another convoy arrive, as sometimes happens, before the first lot of wounded have been disposed of, the admitting officer has an assistant who replaces him in the admitting tent.

As soon as the disposal of the convoy has been determined, the admitting officer—now become director of surgical material—takes position near the operating barrack or tent, in order to keep in constant touch with the stretcher bearers, roentgen-ray and anesthetizing rooms, thus insuring a constant stream of wounded toward the operating rooms and preventing undue congestion at any point. Each squad of stretcher bearers is given its share of the list of operable cases, with their order of precedence; as each wounded man enters the operating barrack, the director verifies the name, diagnosis, etc., and checks them off his list. On completion of an operation, the name and ward number are checked off. As far as possible, a patient who has been operated on should be placed in the service of the operating team; practically this is not always possible while the pooling of cases is in force. Since, however, the operating sheet accompanies the patient, with the name of the surgeon written on it, it is a simple matter to follow the case up and make the proper transfer as soon as the intensity of the battle has abated.



BATH HOUSE, WALKING PATIENTS
To HOSPITAL, WALKING PATIENTS
To HOSPITAL, STRETCHER PATIENTS
WARD FOR LYING PATIENTS
BUFFET
CLERKS
ENTRANCE

Fig. 3.—Another plan of an admitting section of an evacuation hospital.

In order to assure a better postoperative treatment of critical cases, a recovery ward is necessary; in it all of the surgical teams can follow their cases from day to day. A ward surgeon does all of the dressings in the recovery ward, subject to the orders or suggestions of the operating surgeon, who is required to be present during ward walk, in order not to disturb routine work.

SURGICAL DISPENSARY FOR WALKING WOUNDED

During a big "show," valuable saving of time is obtained by appointing a junior officer as dresser for all walking wounded. A section of tent is set aside for this purpose and equipped with sterilizer, instruments and dressings. The dispensary dresser is furnished with a daily list of walking wounded; the latter are sent for, ward by ward, an orderly being detailed for that purpose.

THE ADMITTING TENT BUFFET

Curiously enough, almost the first point to impress on a raw M. C. recruit—surgeon, nurse or orderly—is the all important fact that a wounded soldier is a disabled athlete and not a sick man. With few exceptions this is axiomatic. Casualties arrive at the evacuation hospital after having received a cursory dressing and immobilization, if necessary, in a regimental aid station or field hospital; they may have been fighting for hours or days with little or no time for regular meals; and a tiring meal-less trip of several hours in an ambulance precedes their arrival at the evacuation hospital, the first stopping place where they can get food, rest and radical treatment. I myself am convinced that a goodly percentage of the exhaustion from which they suffer is due to starvation. During the critical battles of this spring, it was no unusual event to receive wounded British and French soldiers who had fought and retreated for five or six days, living on stale bread or hard tack which they happened to have in their knapsacks or pockets. Regardless of the severity of their wounds, nine out of ten soldiers clamor for food before they are discharged from the ambulances. Both the French and British armies have long since recognized this condition and provided for it. The British buffet is always supplied with hot tea, well sweetened, bread, butter and jam. The French serve soup or "rata"—a composite stew of meat and vegetables with Pinard (wine). Soldiers with intra-abdominal lesions should, of course, be excluded from the buffet; practically they are the very ones who manifest no desire for food. While admitting the fact that the giving of nourishment to a patient who may shortly afterward require anesthetizing presents certain esthetic disadvantages, I have yet to see any harm caused by this war custom. Military surgery has given some of our most deeply ingrained surgical notions a rude jolt. The giving of food and omission of the sacramental preoperative purge are two of the least important. When one has seen hundreds of wounded men eating their fill at the buffet and then, deloused, washed up and clothed in clean pajamas, fall into their beds and into profound slumber, from which they awaken a few hours later strengthened and refreshed for their operative ordeal, there can be no further doubt as to the best procedure to follow. Food they must have, prewar notions to the contrary notwithstanding.

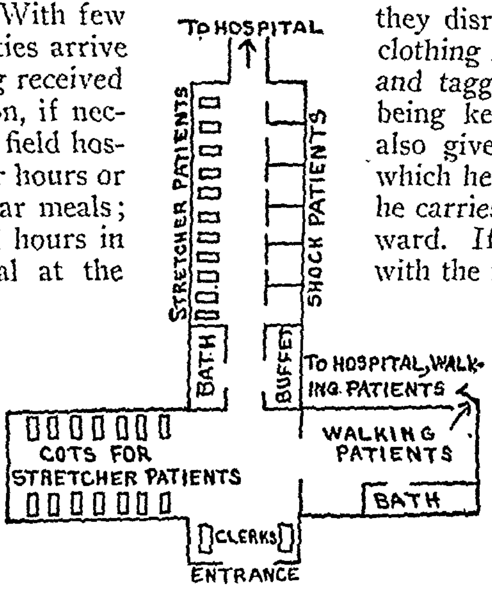


Fig. 4.—A third plan.

The buffet should consist of a section of tent or barrack with tables on each side of its long axis. One table holds tea, cocoa or chocolate, kept hot by means of a Primus lamp, and a sufficient quantity of cups and hot water to wash them in; the opposite table should have bread and butter, sandwiches, hash or some other hot dish. Two orderlies, under charge of a nurse, will suffice, one of the orderlies carrying trays to the stretcher patients.

All walking patients, after being taken up by the admitting clerk, pass directly to the buffet, receive their ration of food, and eat it sitting on rows of benches provided for the purpose. Cigarets are supplied at the same time. A wounded soldier who is not allowed to smoke, when so inclined, becomes an insurrecto on the spot.

THE DELOUSING AND BATHING BARRACK OR TENT

All walking wounded, having eaten and smoked, retire to a screened off portion of the buffet tent where they disrobe from head to foot and roll their clothing into individual bundles which are tied and tagged by orderlies, a duplicate number being kept by the patient. Each soldier is also given a small cotton "treasure" bag in which he places his small personal belongings; he carries this with him to the bath house and ward. If he desires to leave money or jewelry with the registrar, a receipt for it is given him before he leaves the admitting tent.

The equipment of the bathing tent or barrack will necessarily vary with the terrain and available sanitary resources. A pitcher of water, a basin and a cup of kerosene, with soap and towel, represent the essentials; shower baths with hot water are desiderata whenever obtainable.

Each man scrubs the hairy parts of his body thoroughly with the kerosene oil, and then uses soap and water. When dried, a suit of pajamas, pair of socks and slippers are donned and he is directed to his ward.

DIMENSIONS AND PLANS OF ADMITTING SECTIONS

For a 2,000 bed evacuation hospital, five tents or barracks, approximately 6 by 18 yards, will be required. Of these, one is used for admission, one for a buffet and undressing room, two for stretcher cases and one for a bathing room.

By the method of having all the wounded reach their respective wards or operating barrack deloused, cleansed and clothed in pajamas, an immense amount of time is saved and the routine work of orderlies and nurses is not hampered. Though not strictly necessary, a junior officer can be detailed to change all old or foul-smelling dressings in the admitting ward; walking patients should be dressed in the surgical dispensary.

The general plan of the admitting section will necessarily vary with the terrain and available resources of the evacuation hospital. The three herewith submitted have all been successfully used in British, French or American evacuation hospitals.

CONCLUSIONS

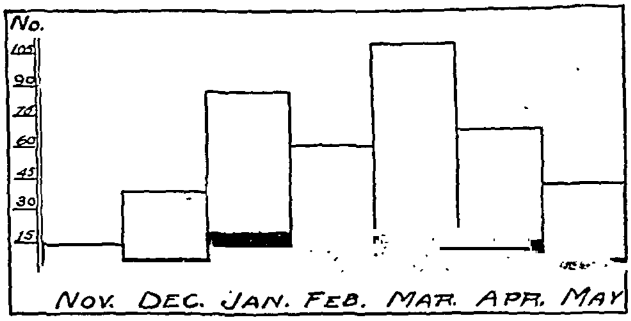
1. The general plan of admission is the result of observations made along the Franco-British front in 1917-1918; the details, as carried out in our hospital, and many original ideas embodied therein, should be credited entirely to Capt. J. D. Bruce, M. C.

2. If carried out, with omissions or additions suggested by divergent conditions of the battle front, the scheme will be found to be both time and life saving.

PNEUMONIA AT CAMP MEADE, MARYLAND

HENRY M. THOMAS, M.D. (BALTIMORE)
First Lieutenant, M. C., U. S. Army; Supervisor of Pneumonia Wards, Base Hospital
CAMP MEADE, ADMIRAL, MD.

From the opening of the base hospital, Nov. 1, 1917, to May 31, 1918, 421 cases of pneumonia have been diagnosed in the wards. Of these, 361 were diagnosed as lobar pneumonia and sixty as bronchopneumonia. We are doubtful as to the accuracy of this differential diagnosis, and in some cases such a differentiation was impossible. Cases with sudden onset, usually with a chill, rusty sputum, continuous high fever, and defervescence by crises between the fourth and tenth day were called lobar pneumonia without consideration of the distribution of pulmonary signs. In a few borderline cases the roentgen ray was of considerable help. There were undoubtedly a number of cases of bronchopneumonia or interstitial bronchopneumonia diagnosed as lobar pneumonia, and we were unable to correct this diagnosis except when the cases terminated fatally. The bacteriology was no help in making the diagnosis, for in two cases of bronchopneumonia and five cases of bronchitis, the Type II pneumococcus was isolated from the sputum. Of the sixty cases diagnosed as bronchopneumonia, only twelve followed measles (the other six measles pneumonias being entered in the record office as lobar pneumonia), and two followed scarlet fever.



Occurrence of pneumonia by months: totals in outline, deaths in black.

Our typical and usual picture of bronchopneumonia was: gradual onset with cough and general malaise often following a bad cold; temperature running an irregular course, usually from 1 to 3 degrees higher at night than in the morning; fever lasting from one to four weeks and ending by lysis; indefinite and variable signs of consolidation in the lungs, often rapidly migratory, and purulent sputum. Most of our forty-six cases were of this description, although there were a few "abortive" cases in which there were only a few days of fever but in which, when examined, definite signs in the lungs were found both clinically and by roentgenoscopy. Such cases, if neglected, might readily have progressed to the more severe type described above. The postmeasles cases were similar except for the extraordinary degree of cyanosis and highly purulent, sometimes salmon colored sputum.

Our figures, then, are only roughly correct from this point of view, but we strongly believe that these two diseases should be considered separately.

TABLE 1.—MORTALITY AMONG WHITE AND COLORED PATIENTS WITH LOBAR PNEUMONIA AND BRONCHOPNEUMONIA

	Number		Died		Mortality	
	White	Colored	White	Colored	White	Colored
Lobar pneumonia............	127	234	28	36	22.0%	11.1%
Bronchopneumonia..........	37	23	10	5	27.0%	21.7%
Total.....................	164	257	38	41	23.2%	15.9%
	421		79		18.7%	

The incidence of pneumonia among the colored troops was roughly eight times as great as among the white troops, there being only about 7,000 colored troops to 35,000 white troops in camp.

In the middle of February a different clinical and bacteriologic picture made its appearance, comprising about ten cases in all. These patients showed marked prostration early in the course, were apprehensive, and were very ill. The physical signs were those of consolidation of one or the other of the lower lobes. As the disease progressed, the percussion note was observed to become flat, and on performing thoracentesis, fluid in quantities varying from a few cubic centimeters to 1 or 2 liters was obtained. This fluid was thin, slightly cloudy, dirty orange colored and usually contained relatively few cells and organisms. The organisms were always found to be *Streptococcus hemolyticus*. Early operation yielded unsatisfactory results, and repeated aspiration succeeded in curing only one case. The procedure finally adopted was aspiration, followed in one or two days by rib resection low in the chest wall under local anesthesia, and the substitution of neutral solution of chlorinated soda for the pleural exudate slowly and only after any shock incident to the operation was recovered from. Four of these cases coming to necropsy showed interstitial bronchopneumonia as described perfectly by Kaufman and noted first in this country by Mathers[1] in his study of a series of cases of pneumonia of atypical cases occurring during and following attacks of grip in 1915-1916. He showed the presence of *Streptococcus hemolyticus* in the sputum and lungs of practically all these cases. Cole and MacCallum[2] have described these cases following measles in the soldiers at Fort Sam Houston, Texas. It is interesting to note that measles was not recognized in any of our cases. The sputum studied in five such cases yielded the Type IV pneumococcus in one and the streptococcus in four (hemolysis was not tested). There were other cases of atypical pneumonia in which the sputum yielded the streptococcus; but without mouse inoculation we are not prepared to say what importance this organism should be given.

---

[1] Mathers: Tr. Chicago Path. Soc., April 1, 1916.

[2] Cole, Rufus, and MacCallum, W. G.: Pneumonia at a Base Hospital, THE JOURNAL A. M. A., April 20, 1918, p. 1146.

During December the sputum of fifteen cases of lobar pneumonia was studied, after which time no more mice were available. These cases all yielded the pneumococcus and none the *Streptococcus hemolyticus*, indicating that at that time the *Streptococcus hemolyticus* was not playing an important rôle in the etiology of pneumonia.

Beginning Feb. 15, 1918, every available sputum was studied by the Avery technic. It is interesting to note that there were certain cases in which no sputum suitable for examination could be obtained, although every effort was made to procure it. We are inclined to believe that they belong to the streptococcus group. In cases in which good sputum was to be had, the Avery technic was altogether satisfactory for the determination of pneumococci when present, and in conjunction with cultures of the sputum directly on blood agar plates made fairly reliable substitute for mouse inoculation. However, mouse inoculation has proved most desirable in the study of sputum in cases in which pneumococci were not present in abundance or when other organisms were to be designated as the causative agent.

TABLE 2.—SPUTUM BACTERIOLOGY, FEB. 15 TO MAY 31, 1918

	Lobar Pneumonia							
Type	I	II	II+	III	IV	Strepto-coccus*	Undeter-mined†	Total
Number	57	26	11	0	27	25	13	159
Per cent.	36.2	16.3	6.8	0.0	16.7	15.7	8.1	100
Died	3	5	2	0	6	2	2	20
Mortality	5.3	19.2	18.2	0.0	22.2	8.0	15.4	12.5
	Bronchopneumonia							
Number	0	0	2	0	9	14	3	29
	Bronchitis							
Number	0	3	2	0	4	10	0	19

* Cases in which the streptococcus was the prevailing organism in the Avery tube after five hours' incubation. Hemolysis was not determined. Many of these sputum specimens were of very poor quality and probably did not yield the etiologic organism.

† For a short period, bile tests were not used, and therefore some of these cases were probably Type IV pneumococcus.

In only one case of pneumonia from which a type pneumococcus (Type I) was isolated from the sputum did streptococcus empyema develop. We take this to indicate that the coexistence of these two organisms was rare in our series.

We are unable to say in what proportion of cases *B. influenzae* occurred. It was seen several times in lobar pneumonia and bronchopneumonia, and doubtless occurred frequently; but during that time our attention was turned toward discovering and treating with serum the Type I pneumococcus cases, and our laboratory staff was not large enough to permit of extensive studies. We did not find *B. influenzae* alone in any case, and doubt its significance in the instances in which it was noted.

PNEUMONIA FOLLOWING MEASLES AND SCARLET FEVER

During the period covered by this report there occurred 316 cases of measles, in eighteen, or 5.7 per cent., of which, pneumonia developed. From the pleural fluid of five empyemas occurring in these cases the hemolytic streptococcus was isolated in four, and the organism was undetermined in the fifth. Of the twelve cases of measles terminating fatally, all were complicated by pneumonia and four also by empyema. In none of these cases was necropsy performed.

The sputum from four postmeasles cases was studied for the pneumococcus. A Type IV pneumococcus was found in three of them and no pneumococcus in the other one. This organism may possibly have a place in the etiology of the pneumonia, but the hemolytic streptococcus found in the pleural exudate is much more reliable evidence. Weichselbaum[3] called attention to the fact that the streptococcus may be present in the lung of a patient dying from pneumonia. The thought occurred to us that very possibly a streptococcus entering the lung as a secondary invader might outgrow the pneumococcus, especially in pleural exudates, and give rise to confusion.

TABLE 3.—MORTALITY IN MEASLES AND POSTMEASLES PNEUMONIA OCCURRING DURING THE SEVEN MONTHS COVERED BY THIS REPORT

	Number		Died		Mortality	
	White	Colored	White	Colored	White	Colored
Measles	243	73	10	2	4.1%	2.7%
Postmeasles pneumonia	15	3	10	2	66.6%	66.6%

From 147 cases of scarlet fever, three cases of pneumonia developed, all of which were complicated by streptococcus empyema. The one specimen of sputum examined yielded a Type IV pneumococcus.

Four patients developed scarlet fever while convalescing from pneumonia, one of whom suffered from streptococcus empyema.

TABLE 4.—MORTALITY IN SCARLET FEVER AND PNEUMONIA FOLLOWING SCARLET FEVER

	Number		Died		Mortality	
	White	Colored	White	Colored	White	Colored
Scarlet fever	147		4		2.7%	
Pneumonia following scarlet fever	3	0	2	0	66.6%	

The incidence of pneumonia following measles and scarlet fever is of peculiar interest at the present time. Scarlet fever is characterized above all other features by its complications, which are almost invariably streptococcal infections; this organism can usually be found in the throat. Pneumonia followed scarlet fever in 2 per cent. of the cases and measles in 5.7 per cent. This would seem to throw some doubt on the importance of the presence of streptococci in the throat flora of measles-pneumonia.

COMPLICATIONS

Of the complications, empyema was by far the most frequently observed.

TABLE 5.—INCIDENCE AND BACTERIOLOGY OF EMPYEMA FOLLOWING LOBAR PNEUMONIA AND BRONCHOPNEUMONIA

	Number	Empyema	Pneumo-coccus	Strepto-coccus	Unknown
Lobar pneumonia	361	22	14	5	2*
Bronchopneumonia	60	18	1	13	4
Unknown lung condition	11	11	0	11	0
Total	432	51	15	29	6

* The staphylococcus was obtained from one case of empyema following lobar pneumonia.

The cases classed as of an unknown lung condition include cases in which empyema was the first chest condition noted. Two followed measles, two scarlet fever, two tonsillitis, one peritonsillar and one inguinal abscess, probably all having some changes in the lung, either bronchopneumonia or interstitial bronchopneumonia. The remarkably high percentage of empyemas following bronchopneumonia is probably due to the fact that the streptococcus was the organism causing, or at least playing a large part in, the infection.

---

[3] Weichselbaum: Med. Jahrb., 1886, p. 550.

The mortality of the pneumococcus empyemas was 40 per cent.; that of the streptococcus empyemas 41.3 per cent.

Two cases of lung abscess were seen following pneumonia, in one of which the patient recovered after operation.

Meningitis complicating pneumonia occurred four times, and was in all cases due to the pneumococcus and always followed lobar pneumonia. These four patients died.

Otitis media was reported in only three cases.

Purulent pericarditis developed in five cases, all of which terminated fatally. The streptococcus was grown from one of the exudates.

Acute nephritis was seen in postmortem examinations in one case, but albuminuria associated with casts occurred quite frequently, clearing up quickly during convalescence.

Pulmonary tuberculosis in patients suffering with pneumonia was diagnosed five times, three of the patients recovering from their pneumonia and returning temporarily to their commands.

Sixteen cases of pneumonia came to necropsy. Four were cases of lobar pneumonia, two of which were complicated by meningitis and one by pulmonary tuberculosis. Eight were of the type of bronchopneumonia usually seen, and four of these patients also had empyema. Four were of interstitial bronchopneumonia complicated by empyema from which the *Streptococcus hemolyticus* was isolated. One of these patients had scarlet fever; the other three cases were apparently preceded only by bronchitis.

TREATMENT

The treatment of all pneumonias was systematized to a certain extent, each patient receiving a course of digitalis and other ordinary routine measures.

All the Type I pneumococcus cases were treated with serum as soon as the organism was ascertained. The Rockefeller hospital technic was followed as closely as Army hospital conditions permitted. In fifty cases treated we have seen nothing which could be construed as harmful effects from serum. Mild anaphylactic reactions were not uncommon but never dangerous, and no lasting complications resulted.

TABLE 6.—TYPE I LOBAR PNEUMONIA

	Number	Died	Mortality
Treated	50	3	6%
Untreated	7	0	0%
Total	57	3	5.3%

The seven untreated patients had their crisis before the type pneumococcus could be determined, either from technical difficulties in the laboratory, or because the patients were seen late in the course, or because the crisis occurred early in the disease.

The three cases that terminated fatally were of the most unfavorable kind, and it seems to us unfair to ascribe these deaths to failure of the serum. One patient had a history of active pulmonary tuberculosis for two years, during which time he had been unable to do any work. At necropsy an advanced pulmonary tuberculosis with cavity formation was found; this condition, while suspected, had been demonstrated only a few days before death. Another patient had been ill five days before entering the hospital, and before treatment could be started had had pulmonary edema for thirty-six hours. The third patient was operated on for empyema on the second day of his pneumonia, shortly after which procedure treatment was instituted. After several days of treatment his temperature remained low and he was apparently recovering. Ten days after the operation, however, he suddenly developed meningitis and died within twenty-four hours. Gram-positive cocci were seen in smears from the spinal fluid, but cultures failed to grow.

We are much impressed by the fact that the earlier in the disease serum treatment was begun the more reliable and prompt was the effect. Cases treated on the second or third day practically never required more than three doses of serum, while our most obstinate cases were treated first on the sixth or seventh day and required more than ten treatments apiece. Crisis on the second, third and fourth day was very frequent among our treated cases of Type I pneumonia and infrequent among the other cases. In the untreated cases of Type I pneumonia, however, there were one or two which showed early crisis—enough, in fact, to prevent our drawing any definite conclusions from this one fact alone.

TABLE 7.—DISTRIBUTION OF LOBAR PNEUMONIAS AMONG THE COMPANIES OF THE THREE HUNDRED AND SIXTY-EIGHTH INFANTRY

Company	B	O	D	E	F	G	I	K	L	M	Hdqs.	Mach. Gun
	IV	S	S	S	II+	IV	IV	S	I	I	I	S

			IV				S		I	I	S	I
			IV				I		I	I		
							I		II	II+		
							I		I	II+		
							I		IV	S		
							S		I	I		
							II+		II+	I		
									I	II+		
Total	2	2	4	1	1	1	9	1	10	10	3	3

The patient mentioned above as dying of meningitis and one other patient who developed streptococcus empyema are the only instances of complications arising in our serum-treated cases.

It seems clear that the general mortality of lobar pneumonias during the period of typing (from February 15 to May 31) was kept as low as 12.5 per cent. by the low mortality in the Type I cases, which comprised 36 per cent. of this total. The part played by the serum is questionable; but the least we can say is that the results are very suggestive.

From the epidemiologic point of view only one regiment yields anything worthy of study. There occurred in the Three Hundred and Sixty-Eighth Infantry, composed of colored troops from Tennessee, forty-seven of the 157 typed lobar pneumonias. The remaining cases were nearly equally distributed among the other regiments of the camp and Laurel Encampment. Table 7 shows the distribution of these forty-seven cases in the regiment.

SUMMARY

The large majority of cases of pneumonia seen at Camp Meade during the past year were typical cases of lobar pneumonia.

The colored troops were much more liable to pneumonia than the white troops, but their mortality was only two-thirds as great as the white troops. The morbidity may be partially explained by the fact that most of the colored troops were from Tennessee, while the white troops came from Maryland and Pennsylvania.

Primary bronchopneumonia or pneumonia following bronchitis is considered a very rare disease in adults. We saw forty-six cases of bronchopneumonia which did not follow measles or scarlet fever or general anesthesia. They presented a fairly distinctive clinical picture. Empyema was a very frequent complication, and from all but two of the pleural exudates a hemolytic streptococcus was isolated.

I wish to emphasize the importance of early recognition of mild cases of bronchopneumonia so frequently passed over as bronchitis. These patients, if not put to bed, may go on to a severe illness.

The cases of interstitial bronchopneumonia seen by us were not in measles patients. One patient had scarlet fever for six days before fluid was detected. They presented a somewhat different picture of sudden onset, generally with a chill, great prostration, nervousness and apprehension. Early and rapid accumulation of fluid which had a typical, thin, cloudy appearance was the rule. The hemolytic streptococcus was recovered from these cases.

The percentage of postmeasles pneumonia, while relatively small (5.7 per cent.), was nearly three times as large as pneumonia following scarlet fever (2 per cent.). I feel that this point is not one to be overlooked in the study of the rôle of the streptococcus in pneumonia.

Serum treatment of Type I cases apparently yielded excellent results. I believe that the mortality was lessened, the febrile period shortened and the number of complications reduced by its use.

Type II pneumococci were recovered from the sputum of several patients suffering from bronchopneumonia and bronchitis. As far as I know, these patients had not come in contact with Type II pneumococcus pneumonia cases.

SERUM TREATMENT OF TYPE I PNEUMONIA

OCCURRING IN ASSOCIATION WITH AN EPIDEMIC OF INFLUENZA

LESLEY H. SPOONER, M.D. (Boston)
Major, M. C., U. S. Army

ANDREW WATSON SELLARDS, M.D. (Boston)
Major, M. C., U. S. Army

AND

JOHN H. WYMAN, M.D. (Medway, Mass.)
Captain, M. C., U. S. Army

CAMP DEVENS, AYER, MASS.

The epidemic of influenza that has passed through Camp Devens has led to a large amount of laboratory investigation, which will be the subject of a future report. It is sufficient to state that *Bacillus influenzae* of Pfeiffer has been established as the etiologic factor in this epidemic. Incident with the rise in the number of cases of the disease, pneumonia, clinically atypical from the classical acute lobar pneumonia, became very prevalent.

A small number of these were demonstrated to be due to *B. influenzae* alone. That many of them were not purely an influenzal process was shown by bacteriologic study of necropsies. Of the patients showing clinical signs of pneumonia, the usual percentage of Type I pneumococci was demonstrated in the sputum (approximately 20 per cent). Blood cultures during life revealed the same type in eight cases.

Since both the influenza bacillus and the pneumococcus were demonstrated so frequently in the sputum of these cases, some doubt arose as to the advisability of treating this mixed infection with an antipneumococcus serum. It is the purpose of this report to state briefly the effect of Type I serum in these cases.

Before the epidemic, serum of low titer (Squibb's) was used in the treatment of typical Type I lobar pneumonias. In this group nineteen recovered and five died—a mortality of 20 per cent. During the epidemic, with essentially the same treatment, thirty-one recovered and twenty-three died, a mortality of 43 per cent. In the height of the epidemic, the laboratory received a supply of high titer serum (Rockefeller). Under careful administration, fourteen patients recovered or are well on the way to convalescence, and one has died—a mortality of 7 per cent. The mortality of Type II was 50 per cent. (two of four patients) before, and 62 per cent. during the epidemic (thirteen of twenty-one patients).

The accompanying table is self-explanatory:

TREATMENT AND RESULTS IN TYPE I PNEUMONIA

Before epidemic:	Recovered, No.	Died, No.	Mortality, Per Cent.
Treated with low titer serum	11	4	27
Complicated by influenza epidemic:			
Treated with low titer serum	12	13	..
Treated first with low titer serum, high titer serum being substituted late in the disease	5	6	..
	17	19	53
Treated with high titer serum	14	1	7

It is not to be assumed that the figure of 53 per cent. represents in any sense the mortality of the pneumonia patients in this epidemic; it applies only to the more seriously ill who were selected for typing, since it was not feasible to type all the patients.

The one patient dying after treatment with high titer serum was admitted to the hospital after an illness of two weeks, in an extremely critical condition.

Not infrequently a moderate elevation of temperature (102 F.) persisted after the administration of liberal quantities of high titer serum (500 c.c.); under these circumstances the injections were usually discontinued, it being assumed that the temperature was probably due to *B. influenzae* or to some other organism than the Type I pneumococcus. A few of the patients improved promptly and definitely soon after the administration of serum; in the majority the improvement was gradual; some remained seriously ill for several days before convalescence began.

It seems inevitable that a certain number of patients must react more or less severely shortly after the injection of serum, especially if it is not carefully prepared. These reactions apparently produce more exhaustion of the patient than might conceivably be caused by moderate exercise. Such reactions can be justified only by the use of high grade serum producing definite and specific benefit to the patient.

SUMMARY OF RESULTS

1. A normal number of Type I pneumococcus pneumonias were found complicating or following influenza.
2. The mortality in this group, when treated with serum of low titer during their entire course, or only in the last stages with high titer serum, was approximately double that similarly treated before the epidemic.

3. An unusually high mortality in Type II cases of pneumonia was found during the epidemic of influenza.

4. Patients treated with high titer serum during the entire disease showed a mortality of only 7 per cent.

5. It is considered inadvisable to inject pneumonia patients with large quantities of low grade serum.

TREATMENT OF INFLUENZA PNEUMONIA BY THE USE OF CONVALESCENT HUMAN SERUM

PRELIMINARY REPORT

L. W. McGUIRE, M.D.
Lieutenant-Commander, M. C., U. S. Navy
AND
W. R. REDDEN, M.D. (Boston)
Lieutenant, Junior Grade, M. C., U. S. Navy
CHELSEA, MASS.

We are all aware of the high degree of fatality resulting from the pneumonia following the influenza of the present epidemic. All of our deaths have been due to the pneumonia complication and none to the influenza as such. Here at the Naval Hospital, the percentage in the first groups reached as high as 50 or 60, and more recently the mortality has dropped to 30 per cent. No doubt this complication will continue to give a high mortality rate, especially when the disease invades new territory. For this reason, we have decided to publish our results in the treatment of a small group of cases, by the use of serum from patients convalescing from pneumonia, following an attack of influenza. It will be readily seen that a complete report at this time is out of the question, but we hope to present sufficient data to indicate the possibility in the use of convalescent serum so that further work can be carried on in territory where the disease is now active, and where proper equipment is at hand to carry out the necessary laboratory details.

Our observation and treatment of more than 400 cases of influenza pneumonia in this hospital has afforded opportunity to compare the various methods of treatment with a fair degree of accuracy.

The use of serum from convalescent influenza pneumonia patients was suggested by the junior writer as possibly having curative value, because of probable antibody content. The reason for this was the experimental evidence presented by Flexner and Lewis[1] with convalescent serum from poliomyelitis patients, and later the clinical evidence presented by Amoss and Chesney[2] during the poliomyelitis epidemic in 1916.

The serum was first tried on two patients, an officer and a nurse, with a very severe and extensive bronchopneumonia.

Case 1.—The officer developed influenza, September 23. On the 26th, he had some evidence of a beginning bronchopneumonia. The temperature was 103; there was some elevation of pulse and respiration. On the 28th, he was desperately ill; the temperature was 104.4, respiration, 36, and pulse 104. He had considerable nausea and vomiting, looked toxic and had beginning cyanosis and vasomotor disturbances; also a profuse sanguinopurulent expectoration. One hundred c.c. of serum were given at 1:30 p. m., and another 100 c.c. at 8 p. m. The next morning, the 29th, the patient was distinctly improved; there were less nausea, cough and expectoration; the temperature was 102, respiration 40, and pulse 104. Seventy-five c.c. of serum were given at 11:30 a. m. On the 30th, a decided improvement was noted. At 8 a. m. the temperature was 100.8, respiration 30, and pulse 88. Seventy-five c.c. of serum were given; the temperature was normal at 4 p. m. The patient was in excellent condition, stating that he felt well. He made an uneventful recovery. The laboratory report of sputum injected into the peritoneum of a mouse showed influenza bacilli and Type IV pneumococcus.

Case 2.—The nurse took sick with influenza, September 24. On the 27th, she had a continuous temperature of 103, respiration 36, and pulse 104. On the 29th, the temperature reached 104, respiration and pulse were the same. Areas of bronchopneumonia were present, especially in the right middle lobe. The patient was very toxic; she was unable to keep anything on her stomach for three days. Water was given by rectum. Marked cough and mucopurulent expectoration were present. At 11 a. m., the 29th, 100 c.c. of serum were given. On the morning of the 30th, the patient ate some breakfast and was much improved, although very ill; the vomiting had practically stopped. The temperature was 103, pulse 114, and respiration 22. Seventy-five c.c. of serum were given. October 1, the temperature was normal; all symptoms subsided and she made an uneventful recovery.

Up to the present time, thirty-seven cases in all have been treated with serum. This represents all the pneumonia patients who have been admitted since October 1, except the officer and nurse previously mentioned. Of this group, thirty are convalescent; six are under treatment; one is dead. Of the six under treatment, two are much improved; two have received only one injection of serum; two patients are not improved, one of whom is critically ill. Of the thirty convalescents, eight received treatment on the second day of the pneumonia; fifteen on the third day; four on the fourth day, and three on the sixth day. Of the six under treatment, three received serum on the second day; two on the third day, and one on the fourth day. The patient who died received the first serum on the fifth day.

SERUM TREATMENT

Convalescent patients were bled as soon as convalescence was well established, the majority within a week or ten days of a drop to normal temperature. The serum was given as early as the diagnosis of the pneumonia complication could be made, so there has been no doubt about the lung involvement. The dose of serum has varied from 75 to 125 c.c. intravenously, and the interval between doses has varied from eight to sixteen hours.

Treatment was continued until there was no doubt about the recovery of the patient. The majority received about 300 c.c. Three received only 100 c.c., and two received from 600 to 700 c.c. It was found, as we anticipated, that there was a marked difference in the potency of the convalescent serum. At least ten out of seventy serums had no effect on patients. Under these conditions, the succeeding doses of serum were from other patients. Results from this serum are usually obtained in the first twenty-four hours after its use. If no results are obtained by this time, the serum from another donor should be used. An attempt was made to judge the potency of the serum by the amount of the lung involvement. This was done by obtaining a careful statement of the physical findings and the clinical course of the disease in the donors.

PROCEDURE

Wassermann tests were made on all donors as soon as possible in order not to waste time on bleeding those who showed a positive reaction.

Compatibility tests of donors' serum, with recipients' corpuscles, was made as soon as new cases appeared in the ward. Then usually from ten to fifteen serums were tested against the corpuscles of each recipient in order to have plenty of available serum for complete treatment.

Blood to the amount of about 800 c.c. was taken from each donor, under sterile precautions, 400 c.c. at a time on two successive days. Thus each donor yielded about 300 c.c. of serum. The blood was allowed to clot at room temperature for about an hour; then plate cultures were made, and the containers placed on ice over night. The separated serum was cleared by centrifugalizing at high speed, then bottled, and in most cases given the same day. Tricresol (0.3 per cent.) was used only in serum kept over twenty-four hours. It is interesting to note that only four patients had chills after the serum injections. All of these received serum containing tricresol, while three others receiving tricresolized serum gave no such reaction. At no time has a donor been inconvenienced by the withdrawal of the foregoing amount of blood. In fact, the majority wanted to give more.

An attempt has been persistently made to test the potency of the serum of the donors by complement fixation and by gross agglutination, using the recently isolated influenza bacillus as an antigen; but as yet we have found no method of testing the antibody content of serum except by its clinical action on recipients.

SUMMARY AND CONCLUSIONS

Treatment of influenza patients with the pneumonia complication by the use of convalescent serum was started at this hospital, Sept. 28, 1918.

Up to the time of writing, thirty-seven pneumonia patients have been treated. Of this group, thirty are convalescent; six are under treatment; one has died; all but one of these have a favorable outlook.

At present, the potency of the convalescent serum can be tested only by its clinical effect. Further attempts are being made to titer the serum.

Experience shows that the most beneficial results will be obtained by giving the proper serum within the first forty-eight hours of the pneumonia complication.

It has been our observation that the virulence of the organism has decreased in this hospital as the epidemic progressed; but making allowance for this diminution in severity of the pneumonia cases, it is believed that the serum from convalescent influenza pneumonia patients has a decided influence in shortening the course of the disease and in lowering the mortality.

This treatment requires the cooperation of a well equipped laboratory, where the proper laboratory procedure, as previously noted, can be performed, and should be used only by those who are prepared to have this necessary laboratory work carried out.

U. S. Naval Hospital.

Keep Wounded Quiet.—Since any sort of activity increases the demands of the tissues for extra oxygen, every care should be exercised to keep wounded men quiet. The tissue or cellular acidosis will thus be reduced to a minimum.—*Review of War Surgery and Medicine.*

DERMATOLOGY IN A BRITISH GENERAL HOSPITAL IN FRANCE [*]

INCLUDING THE DIFFERENTIATION OF "I. C. T." (INFLAMMATION CONNECTIVE TISSUE)

FRANK CROZER KNOWLES, M.D. (Philadelphia)
Captain, M. R. C., U. S. Army; Dermatologist, U. S. Army Base Hospital No. 10
FRANCE

A year has now elapsed since this unit of the American Army took charge of this large British Hospital in France, and it will prove interesting to give in some detail the dermatologic phase of the work.

The dermatologic department consists of a hut containing forty-eight cots, and three tents, the largest holding forty and each of the others twenty; the four wards have a capacity of 128 patients. The bathing arrangements consist of four baths, two for scabies in a separate building, and one each for the transient venereal patients and the other skin cases, each in a separate room. Adequate sterilization is carried out for these patients' clothes. The staff consists of the officer in charge, a noncommissioned officer and two, occasionally three, enlisted men.

TABLE 1

Condition	No.	Condition	No.
Abscess	50	Lupus erythematosus	1
Angioneurotic edema	3	Lupus vulgaris	1
Acne	5	Molluscum contagiosum	1
Acne varioliformis	2	Pityriasis rosea	10
Alopecia areata	3	Psoriasis	26
Boils	381	Pompholyx	2
Callositas	8	Papilloma	2
Carbuncle	7	Purpura	5
Dermatitis herpetiformis	1	Pediculosis corporis	10
Dermatitis	35	Pediculosis pubis	8
Epithelioma	2	Pernio (frost bite)	50
Erythema multiforme	4	Paronychia	3
Erythema nodosum	1	Seborrhea	5
Erythema (toxic)	7	Sycosis vulgaris	4
Eczema	51	Scabies	510
Eczema seborrhoicum	6	Septic ulcer	210
Ecthyma	209	Schoenlein's disease	1
Erysipeloid	1	Syphilis (secondary)	37
Folliculitis	5	Syphilis (late)	15
Herpes simplex	1	Tinea circinata	2
Herpes zoster	18	Tinea cruris	6
Hyperhidrosis	56	Tinea versicolor	3
Ichthyosis	4	Tinea sycosis	5
Impetigo	122	Urticaria	7
Keratosis palmaris et plantaris	1	Vitiligo	2
Keloid	1	Von Recklinghausen's disease	1

There have been 1,913 skin cases treated during the twelve months period. This number does not include the 462 patients who remained here one or two days en route to venereal hospitals. This total also does not take count of many cases of urticaria and toxic erythema that developed in patients admitted to the hospital with other conditions; the toxic erythema has been chiefly observed following the injection of antitetanic serum. The very large number of patients admitted as battle casualties only a few hours from the battle line showing pediculi in their clothing or "nits" on the pubic and axillary hairs are also not included in the total just mentioned. As an example of the prevalence of "nits" on the hairs (pediculosis pubis), a few days following the admission of a large number of battle casualties, I examined 200 patients, of which number 190 showed ova.

Table 1 gives the variety and number of cases of each skin condition treated.

In a war in which millions of men are involved and in which there are of necessity thousands of wounded and sick, certain class names have been given to various diseases, and their correct differentiation remains for elucidation to the specialist in the line to which the name is applicable. This differentiation frequently, because of the haste required in evacuation nearer the line, remains to be carried out in a base hospital or in some special center.

---

[*] From the Skin Department of No. 16 (Philadelphia, U. S. Army) General Hospital, B. E. F.

To an American dermatologist one of the most interesting class terms used in the present war is "I. C. T." (inflammation connective tissue), the synonym of the American Army term "pyodermia." These so-called I. C. T. cases are eventually weeded out into their proper nomenclature, in the event that a trained dermatologist is present at their final destination. Like so many class terms, however, I. C. T. is frequently used to cover a diagnosis so diametrically opposite from the original intention that a dermatologist's opinion is absolutely necessary.

Out of the 1,913 skin cases admitted to this hospital during the last twelve months, 995 have borne the diagnosis of I. C. T.

Table 2 shows these I. C. T. cases differentiated into their proper nomenclature.

TABLE 2.—DIFFERENTIATION OF I. C. T. CASES

Condition	No.	Condition	No.
Abscess	50	Folliculitis	10
Ecthyma	170	Hyperhidrosis	50
Septic ulcer	210	Pernio (frost bite)	25
Boils	211	Callositas	12
Scabies	86	Herpes zoster	2
Carbuncle	5	Pityriasis rosea	1
Dermatitis	17	Tinea versicolor	1
Impetigo	139	Syphilis (late)	6

Several hundred other cases diagnosed as I. C. T. on the "field card" have been excluded from this review as they comprised purely surgical conditions, such as gangrene of the feet, advanced stages of so-called trench foot, bone felon, necrosis of the bone, deep seated carbuncles, abscesses, and flesh wounds of various types.

Several points should be particularly emphasized in our review. First, many skin conditions may be treated over a considerable period without avail, either because of improper medication or because of an incorrect diagnosis. The latter point is well exemplified, as twenty cases of syphilis, eight in the second stage and twelve showing late skin lesions, were admitted to the hospitals improperly diagnosed.

Scabies also under war conditions is very different from that seen in civil practice, as the hands, and not infrequently the wrists, show little or no eruption, and pus complications are extremely frequent. Ecthyma, which occurs very rarely in private dermatologic practice and which is seen only in the poorest and most unkempt type of dispensary patient, is here very prevalent. Septic ulcer is another war complication that is of frequent occurrence and starts primarily with a mild trauma and is not infrequently observed on the feet, often over the Achilles tendon.

Emphasis should be laid on the fact that greater care is required in diagnosing between active and nonactive lesions of the skin. In numerous instances, patients have been sent to the hospital showing only pigmented marks (stains) on the skin, those areas signifying merely that inflammatory lesions had been present but that the active quality (redness) had entirely disappeared; following severe inflammations it may require many weeks for the stain entirely to disappear.

War dermatology, as consulting these tables plainly shows, consists chiefly of animal parasitic diseases and their complications. Exposure, skin trauma, and vegetable organisms are responsible for a large toll.

CONCLUSIONS

All diseases of the skin, exclusive of uncomplicated cases of scabies, and pediculosis, should be treated in areas where dermatologic advice is available.

All patients with skin diseases requiring prolonged treatment should be sent to special hospitals or to special wards in designated hospitals where they will be under the care of a dermatologist.

Many wounded and sick patients have skin diseases which may be of unusual types, such as late manifestations of syphilis, or rare conditions. A dermatologist subject to call under such conditions is indispensable.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

BENZYL ALCOHOL.—Phenmethylol.—Methylhydroxy Benzene.—$C_6H_5CH_2OH$.—An aromatic alcohol occurring as an ester in tolu and other balsams, and also produced synthetically by various processes.

Actions and Uses.—Benzyl alcohol is now being used as a local anesthetic by injection and on mucous membranes. It is said to be practically nonirritant and nontoxic in the ordinary concentrations and doses.

Dosage.—Benzyl alcohol is usually used in the form of a 1 to 4 per cent. solution in water or physiological sodium chloride solution. Such solutions may be sterilized by boiling, without danger of decomposition. Pure benzyl alcohol is markedly antiseptic. The technic of injection is the same as for other local anesthetics.

Benzyl alcohol is a colorless liquid with a faint aromatic odor, and a sharp burning taste. When placed on the tongue it produces numbness, even in very small quantities. It is soluble, 1 Cc. in 25 Cc. water, and miscible in all proportions with alcohol, ether, and chloroform.

Benzyl alcohol boils without decomposition between 200 and 206 C. When ignited it burns with a smoky flame.

It has a specific gravity of from 1.040 to 1.050 at 15 C., and 1.032 to 1.042 at 25 C.

Benzyl alcohol is neutral to litmus. If 2 or 3 *drops* are added to a *strong solution* of potassium permanganate acidulated with sulphuric acid, rapid oxidation takes place and the odor of benzaldehyde is plainly evident. On heating the mixture further oxidation takes place and then by adding dilute sulphuric acid and decolorizing the mixture with hydrogen dioxide, benzoic acid may be obtained by extracting with ether.

When volatilized in a Bunsen flame from an oxidized copper wire, no green color should be imparted to the flame (*chlorinated products*).

If 5 Cc. are shaken with 5 Cc. sodium hydroxide solution (5 per cent.) and allowed to stand one hour, no yellow color should appear in the aqueous layer (*aldehyde*).

Ten Cc. benzyl alcohol should leave no weighable residue on evaporation and heating until all carbon is burned away.

Phenmethylol-H. W. & D.—A nonproprietary brand of benzyl alcohol complying with the tests and standards for benzyl alcohol.

Manufactured by Hynson, Westcott & Dunning, Baltimore, Md.

Phenmethylol Ampules, 1 per cent.-H. W. & D.—Ampules containing 5 Cc. of a sterile solution of benzyl alcohol 1 Gm., in physiological sodium chloride solution 99 Gm.

Phenmethylol Ampules, 2 per cent.-H. W. & D.—Ampules containing 5 Cc. of a sterile solution of benzyl alcohol 2 Gm., in physiological sodium chloride solution 98 Gm.

Phenmethylol Ampules, 4 per cent.-H. W. & D.—Ampules containing 5 Cc. of a sterile solution of benzyl alcohol 4 Gm., in physiological sodium chloride solution 96 Gm.

SATURDAY, OCTOBER 19, 1918

THE BACTERIOLOGY OF MEASLES

In view of the deep concern felt in regard to measles since the recent experiences in our military camps, the summary in The Journal last week[1] of the literature on the bacteriology of this disease and its complications is of timely interest. It is evident that much of the work, especially the earlier, now has no value except possibly in a historical sense and as illustrative of the by-products of the development of bacteriologic science. The three bacteria that stand out as of most importance in connection with measles and its complications at this time appear to be the streptococcus, the influenza bacillus (using these names in a general sense) and the coccus recently discovered by Tunnicliff in the blood in the very early stages of measles and in the throat and nose. Of course, the pneumococcus, the diphtheria bacillus, the staphylococcus, etc., may cause complicating infections occasionally in measles, but so far as we know now not much oftener than in other acute infectious diseases.

The Tunnicliff coccus is a new factor, the exact significance of which is to be determined. At present it represents "the mysterious stranger" in the bacterial groups associated with measles. It may be the cause of the disease itself—it occurs in the blood even before the rash, and the patient responds to its presence by producing specific antibodies. Or it may be an early secondary invader coming in closely on the heels of the measles virus proper. The situation may seem to some, especially those who are prepossessed in favor of the view that measles is caused by a filtrable virus, as in certain ways similar to that which has developed in case of epidemic poliomyelitis by the demonstration by Mathers, Rosenow, Nuzum and Herzog and others, that a coccus, which may be classed as a nonhemolytic streptococcus and which in some ways resembles the Tunnicliff coccus, apparently occurs regularly in the central nervous system in poliomyelitis. So long as experimental poliomyelitis has not been produced by means of pure cultures of this coccus but can be produced by emulsions of poliomyelitic nervous tissue, we are practically driven to conclude that the coccus is a secondary invader and that the reported benefits of the serum of horses injected with the coccus may be due to its action on the coccus rather than on the primary cause. In both measles and epidemic poliomyelitis the infection is believed to enter the body by way of the throat and nose, and in so doing perhaps it opens the door for cocci normally present in the nasopharynx in small numbers. But enough of speculation! It is evident that further observations and experiments of a crucial character are needed to settle the questions raised in regard to the Tunnicliff coccus.

The part played by the influenza bacillus in measles is not clearly established. There seems to be no doubt, however, that it occurs more frequently by far in the throat and nose and in the lungs in measles than in health. This bacillus seems to have a somewhat similar relation to whooping cough and scarlet fever as to measles, and the reasons for this association as well as its possible dangers to the patient are difficult problems that should not be neglected.

It is interesting that the presence of streptococci in measles bronchopneumonia was recognized in practically the first bacteriologic investigation of measles, namely, by Babes, and by Cornil and Babes, as long ago as the early eighties of the last century. In spite of these early observations and of the later observations by Craig, Lorey and others, this bronchopneumonia and other complicating infectious lesions did not receive due consideration, especially from the point of view of spread and prevention, until the recent and highly valuable work in our American Army camps. Here it has been shown that hemolytic streptococci may spread rapidly among persons closely associated, and especially among measles patients when cared for in wards in the old way without individual isolation, and cause extensive outbreaks of bronchopneumonia; further, that when the patients are isolated under conditions that prevent contact with persons, including fellow patients, that may harbor streptococci, streptococcus bronchopneumonia and other serious infectious complications may be avoided. It is evident, of course, that this new and more complete individual and selective isolation, including protection by means of face masks and other measures[2] against transfer by mouth, throat and nose bacteria, tends to avoid not only streptococcus but also other infections.

It has not been determined whether the streptococci concerned in the bronchopneumonia in measles and other allied conditions are of the same strain or belong to different groups. Only hemolytic streptococci have been encountered thus far in the bronchopneumonia in our camps. It is altogether probable that not much can be done by way of protective inoculation before we learn more about the unity or plurality of streptococci and their immune reactions. Lathrope[3] reports a remarkable outbreak of acute mastoiditis after measles and other infectious diseases, and here streptococci of the *S. viridans* type appeared to predominate. Further observations are required to establish definitely the part taken in such processes by nonhemolytic streptococci. Advocates of the view that localization of streptococci may depend on more or less newly acquired special "affinities" naturally will find strong support for this view in the report by Lathrope.

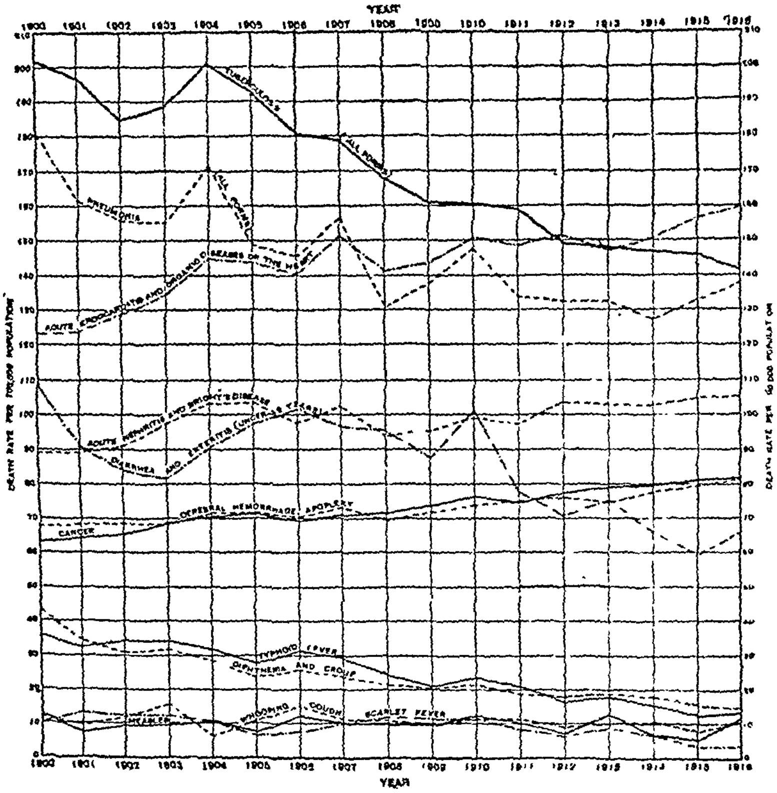
[2] Weaver, G. H.: The Value of the Face Mask and Other Measures in the Prevention of Diphtheria, Meningitis, Pneumonia, etc., The Journal A. M. A., Jan. 12, 1918, p. 76. Capps, J. A.: A New Adaptation of the Face Mask in Control of Contagious Disease, March 30, 1918, p. 910; Measures for the Prevention and Control of Respiratory Infections in Military Camps, Aug. 10, 1918, p. 448. Haller, D. A., and Colwell, R. C.: The Protective Qualities of the Gauze Face Mask, Oct. 12, 1918, p. 1213. Doust, B. C., and Lyon, A. B.: Face Masks in Infections of the Respiratory Tract, p. 1216.

Still another perplexing question is this: Why in the assembling and training of new armies in other countries, like England and France, did not similar outbreaks of serious streptococcus complications arise after measles? We cannot say whether the decisive factor has been a definite racial susceptibility on our part or the evolution here for some reason of especially virulent streptococci. It is true that our Southern troops appear to be more susceptible to infections than Northern troops, but the study so far given to this problem leaves us still in the dark.



Changes in death rate, 1900-1916.

The many problems that remain unsolved must not lead us to belittle in any way the recent advances. The nature, dangers, mode of spreading, and means of prevention of bronchopneumonia in connection with measles and other diseases are now better understood than ever before. In 1847, in his classical study of measles in the Faroe Islands, Panum wrote that isolation is the way to prevent its spread. Today we can say that the way to prevent the complication that more than anything else makes measles a dangerous disease, namely, streptococcus bronchopneumonia, as well as other secondary infections, is also isolation—prompt, selective and protective. This new principle must now be applied in private practice and in civil hospitals, because undoubtedly even here many deaths from bronchopneumonia and secondary infections generally in measles and other acute diseases are preventable.

MORTALITY STATISTICS FOR 1916

The report of the Bureau of the Census on the mortality statistics covering the registration area for 1916 has just appeared. The death rate was 14 per thousand population, slightly exceeding the rates for 1914 and 1915, which were 13.6 and 13.5, respectively, but slightly lower than that for 1913, which was 14.1. Of the 1,001,921 deaths that occurred in the registration area, 54.7 per cent. were males and 45.3 per cent. famales. Infants under one year of age constituted 16.4 per cent. of all deaths, continuing the gradual decrease that has taken place since 1900 in deaths of infants under 1 year. In 1900 this rate was 20.7 per cent. of the total. The deaths of infants under 5 years have gradually decreased from 30.4 per cent. of all deaths in 1900 to 23.4 per cent. in 1916. The highest death rates in 1916 occurred in Maryland with 16.5; Connecticut, 16.3, and New Hampshire, 16.1; the lowest rates in Washington, 7.7; Colorado, 10.3; Utah, 10.4; Minnesota, 10.7, and Kansas, 10.9.

The accompanying chart indicates the changes in the death rate from certain important causes of death from the years 1900 to 1916. The death rate from tuberculosis continues gradually to decrease; the rate for pneumonia, though gradually decreasing, showed a slight rise in 1916; the death rate from diseases of the heart continues to rise gradually. The death rate from intestinal diseases of infants under 2 years continues gradually to decrease; the rate from cancer and from nephritis and Bright's disease continues at a very gradually increasing level. Typhoid fever and diphtheria likewise continue at a low rate without marked decrease or increase, and in the same way measles, whooping cough and scarlet fever change but little during this period.

Throughout the mortality statistics the one outstanding feature is the much higher death rate that persists among the colored as compared with the white population. This can, of course, be accounted for by many well-known factors.

---

[3] Lathrope, G. H.: Acute Mastoiditis as a Complication of Infectious Diseases, The Journal A. M. A., Aug. 10, 1918, p. 451.

At this time it is interesting to note the mortality from influenza in 1916. In that year influenza developed in epidemic form and caused 18,886 deaths, equivalent to a rate of 16.4 per hundred thousand population, representing an increase of 65 per cent. over the rate for 1915, which was 75 per cent. higher than that for 1914. The rate for this disease will undoubtedly be higher for 1918 than for 1916.

The death rate for suicide in the registration area for 1916 was the lowest recorded for the past ten years. The five states that showed the highest rates were California, Montana, Indiana, Vermont and Missouri. The five states with the lowest rates were North Carolina, South Carolina, Kentucky, Virginia and Kansas. The five cities with the highest rates were San Francisco, Bridgeport, Conn., Omaha, Los Angeles and Indianapolis. Those cities with the lowest rates were Scranton, Pa.; Lowell, Mass.; Birmingham, Ala.; Richmond, Va.; Cambridge, Mass., and Buffalo. The most notable increase that occurred in any city occurred in Indianapolis, an increase of 27.9 against 16.9.

Excluding suicides, various forms of violence caused 65,121 deaths in 1916. This heading includes death from accidental and undefined causes, as well as those from homicide. There were 5,050 murders in 1916. The greatest number of violent deaths represent human carelessness and instability, since 10,775 deaths followed traumatism from falling; railroad accidents and injuries accounted for 8,127; accidental burning, 6,185; burns, 5,726; automobile accidents, 5,193, and gas poisoning, 2,927, all representing increases from 1915, except accidental burning. The rate of death from automobile accidents has advanced steadily since 1906, when it stood at 0.4 per hundred thousand, to 1916, when it stood at 7.3. Twenty-seven and nine-tenths per cent. of the total number of deaths from automobile accidents were of children under 15 years of age. The five cities showing the highest rate for automobile accidents are, in order, Detroit, Bridgeport, Conn., Los Angeles, New Haven, Conn., and Cleveland; the five cities showing the lowest rates are Spokane, Louisville, Ky.; Fall River, Mass.; Portland, Ore., and Lowell, Mass. The rates for three large cities are: Chicago, 9.7; Philadelphia, 8.9, and New York, 7.7.

Of course, one of the greatest factors affecting statistics of the causes of death is the accuracy of physicians' reports. The Census Bureau has made a continuous endeavor to increase accuracy, and results show a gradual improvement. The bureau has sent to physicians two pamphlets bearing on this subject, namely, "The Relation of Physicians to Mortality Statistics," and "The Physician's Pocket Reference to the International List of Causes of Death." Physicians should study these carefully and endeavor to use definite terms in reporting causes of death. The value of mortality statistics in determining lines of endeavor for prophylaxis against disease cannot be overestimated. Every physician should do his utmost to aid in securing accuracy.

It is to be regretted that the publication of these annual reports is still sadly delayed. There certainly can be no good reason for a delay of more than a year and a half.

OXIDATION IN THE BODY

The French scientist, Lavoisier, who first discovered the true importance of oxygen and gave it its present name, early declared that life processes are those of oxidation with the elimination of heat. In his classic researches which opened the modern era in the science of nutrition before the close of the eighteenth century, he established the fundamental fact that the quantity of oxygen absorbed and of carbon dioxid excreted depends primarily on food, work and temperature. Although many years subsequently it was not uncommon to hear that oxygen determines metabolism, the reverse has become firmly established today, namely, that the extent of metabolism determines the amount of oxygen to be absorbed.

The problem of how the physiologic oxidations are initiated and carried out has been a perplexing one to a generation or more of chemically trained investigators. It seems remarkable, of course, that our foodstuffs and their simpler derivatives should be oxidized to their end-products under conditions in which oxidation reactions cannot readily be carried out in the laboratory. Fats and sugar, for example, are not easily converted into carbon dioxid and water by mere contact with oxygen at body temperature. It seems reasonable to postulate some intermediating agency like an enzyme in the physiologic execution of the oxidative change. Burge of the University of Illinois has championed such a view. He has found that many performances which increase oxidation in the body also stimulate the liver to an increased output of catalase, an enzyme in the tissues having the property of liberating oxygen from peroxids. The conclusion is reached by this physiologist that catalase is the enzyme principally responsible for oxidation in the body. In the latest experiment in relation to this topic,[1] a comparison has been made of the catalase content of the blood before and after introduction of food materials into the body. Thus it was found that simple sugars rapidly led to an increase in the oxygen-liberating enzyme—in some cases as much as 40 per cent. above normal; with fats there was also a pronounced gain, the rapidity of its occurrence depending on their rate of alimentary absorption. Meat, as a specimen of protein food, provoked an increase in proportion to the liberation of its digestion derivatives ready for transport in the circulation. Moderate exercise also had an augmentative effect on the enzyme concentration in the blood; although work up to the stage of extreme fatigue had an effect quite different.

---

[1] Burge, W. E.: How Food and Exercise Increase Oxidation in the Body, Science, Aug. 16, 1918, p. 174.

From observations of the sort hastily reviewed, the conclusion is drawn by Burge that food and exercise produce an augmentation in catalase with resulting increase in oxidation by stimulating the liver to a larger output of this enzyme. There is a tendency to quote such statements without a due recognition of the limitations to our knowledge contained in them. It is one thing to observe the liberation of oxygen from peroxid in a test tube under the influence of a tissue extract or fluid; quite another problem is concerned in connecting such experimental facts with the complexities of reaction demanded by the known conditions of tissue oxidation. The mechanism of the latter remains, now as before, obscure and a subject for explanation.

Current Comment

VACCINES IN INFLUENZA

With the appearance of the epidemic of influenza, reports began to appear, chiefly in newspapers, as to new serums, vaccines, drugs and other methods for checking and even for curing the disease. A few samples of such as have come to THE JOURNAL appear in our Tonics and Sedatives Department this week. In Massachusetts, Commissioner E. R. Kelly appointed two committees to investigate the value of influenza vaccines as a preventive agent and as a treatment of the disease. The first committee, a special board for scientific investigation, consisting of Dr. M. J. Rosenau, chairman, and Frederick P. Gay and George W. McCoy, was appointed to consider the evidence available on the prophylactic and therapeutic use of vaccines against influenza. This committee presented the following conclusions:

> 1. The evidence at hand affords no trustworthy basis for regarding prophylactic vaccination against influenza as of value in preventing the spread of the disease, or of reducing its severity. The evidence from the present epidemic, though meager, suggests that the incidence of the disease among the vaccinated is smaller than among the nonvaccinated. The board, therefore, concludes that further experimental evidence should be collected.
>
> 2. The evidence at hand convinces the board that the vaccines we have considered have no specific value in the treatment of influenza.
>
> 3. There is evidence that no unfavorable results have followed the use of the vaccines.

The second committee, known as the Special Board of Statistical Investigation, consisted of Dr. George C. Whipple, chairman, William H. Davis and F. C. Crum. This committee reported:

> 1. The weight of such statistical evidence as we have been able to accumulate indicates that the use of the influenza vaccine which we have investigated is without therapeutic benefit. Exceptional cases where apparent benefit has resulted from the use of the vaccine can be matched by other cases where similar recoveries have been made without vaccination.
>
> 2. The statistical evidence, as far as it goes, indicates a probability that the use of this influenza vaccine has some prophylactic value.
>
> 3. There is also some evidence to the effect that other methods of protection, such as open-air treatment and the use of proper masks, are effective in protecting exposed attendants, and the use of vaccine should not be taken as an excuse for omitting such safeguards.

As a result, the following recommendations were made:

> That the state encourage the distribution of influenza vaccine intended for prophylactic use, but in such manner as will secure scientific evidence of the possible value of the agent. The use of such vaccine is to be regarded as experimental.
>
> That the state shall neither furnish nor endorse any vaccine at present in use for the treatment of influenza.

These reports are conservative, and offer to other health commissioners and their communities a reliable guide as to procedures that should be adopted before subjecting or trying out on the public any method of prevention or treatment that may be offered. These matters are the domain of medical science, and medical scientists of recognized ability should be called on to make the decision.

SCHEDULE OF STUDIES FOR PREMEDICAL STUDENTS

On another page[1] is published a special circular from the Committee on Education and Special Training of the War Department, which gives the program of studies for premedical students in the Students' Army Training Corps. The course is arranged only for the first three months of the college year and consists of inorganic chemistry, 21 hours per week; biology, 12 hours per week, and war issues, 9 hours per week; or a total of 42 hours of professional instruction, to which are added 11 hours per week of military instruction consisting largely of drill and physical training. As we intimated recently,[2] this course was previously outlined for students in the Divisions of Chemistry and Chemical Engineering, the only change being the substitution of twelve hours of biology for the twelve hours of mathematics. As suggested in the special circular, premedical students may profitably be taught their chemistry in the same classes with students in the Division of Chemistry and Chemical Engineering. Special classes in physics, chemistry and biology will be provided for students who have already completed their first year of premedical work, so that in the shortest time possible they may complete the balance of the work in those subjects at present required for admission to medical schools. The schedule of work for the balance of the premedical course is to be submitted later. The entire premedical course is to be condensed so that it may be completed in four quarters (instead of six) of twelve weeks each. The eleven hours per week of required military instruction will provide the physical training highly desirable for students who are expected to master the work laid down in this condensed schedule. In the past, it has been claimed that the curricula of our colleges of liberal arts have been so easy that they fail to develop the students' powers of industry and application. Permanent changes in their curricula may result, therefore, if the present plan of instruction for premedical students works out as well as it is hoped by those who prepared it.

EFFECT OF QUININ ON PROTEIN METABOLISM

There are numerous drugs known to stimulate metabolism and facilitate the destructive disintegration of protein in the body. Few, on the other hand, are the instances of decreased nitrogenous metabolism attributable to the action of chemical compounds introduced into the organism in pharmacologic doses. Quinin is an illustration of the latter type; it is known to affect the nitrogen balance in a favorable way, so that the use of the drug in fevers attended with considerable tissue destruction has even been defended on the basis of its conserving effects. Riddle and Anderson[1] of the Station for Experimental Evolution at Cold Spring Harbor, Long Island, have demonstrated the comparable behavior of quinin on structures specifically concerned with the production or secretion of protein. Thus the drug was found to have a conserving action in birds on functions of the oviduct, the essential output of which is the egg albumin. The amount of this was abnormally decreased under quinin fed to laying ring-doves; there was also a reduced size of the yolks. The investigators believe the reductions and fluctuations in size of the ova are consonant with the view that, in these cases, the size attained is governed by restrictions placed on the protein metabolism rather than on the general metabolism.

VOLUNTARY ACCELERATION OF THE HEART BEAT

Ability to bring about voluntary acceleration of the heart beat in man is a rare and interesting accomplishment. West and Savage[2] of the Peter Bent Brigham Hospital, Boston, have just recorded the fifteenth authentic case in medical literature. The subject was a healthy medical student who had no cardiovascular symptoms and had never experienced attacks of tachycardia. He discovered the ability to increase his heart rate voluntarily during the course of his studies in physiology. During the period of acceleration there is a slight increase in the rate and the depth of respiration, and the pupils dilate moderately as recorded by other observers. No definite physical effort is made, but constant mental concentration must be maintained, which, after several closely repeated trials, becomes quite fatiguing. The current belief as to the mechanism of this acceleration assigns the chief participation to the action of the accelerator nerves.[3] The further possibility that the speeding up of the heart may be due to release from vagus inhibition has usually been rejected. In the new case, atropin, which paralyzes the vagus endings in the heart, had an undeniable effect in decreasing the ability voluntarily to change the heart rate. Therefore West and Savage believe that in this person their observations "point more to vagus than to accelerator domination during periods of acceleration." It is doubtless the same mechanism that accounts for the acceleration accompanying exercise. At present, however, it cannot be denied that both vagus and accelerator nerves may share in the speeding up of the heart, or that the effect of each may, if necessary, augment that of the other.

Medical Mobilization and the War

THE AMERICAN DOCTOR IN ENGLAND

Sir William Osler sends the following poem from the *Westminster Gazette* of September 18, in which it was published under the caption "The Doctor." He says that it "expresses well what the patients think of the American boys in the English hospitals. They have done splendidly. We have a dozen fine fellows in the orthopedic department here. The enthusiasm for the U. S. is intense—and how well deserved!"

Oh, it's grand of a man who comes five mile
For the sake of your pain-racked form;
Who will leave his rest with a cheery smile,
And the darkness dare or the storm.
Who has ne'er a sigh though his door-bell ring
When the hour of the morn is small,
But hurries along, though the shrill winds sting,
At the haste of a patient's call.

Oh, it's grand, is it not?—and just as true
That he prides himself not a whit,
But is glad if his skilled hand bring to you
Some ease in the soothing of it.
His duty?—just so! but it's grand no less,
No matter the time or the task,
That he readily gives in hours of stress
Of his gifts—and to all who ask.

But what shall you say of the man I know,
Who, to ease our aching and pain,
Has come not five but five thousand miles so
In darkness, in blast, and in rain?
Oh, it's grand when I think—you'd think so too!—
(Though you honor your own no less)
To lie in a ward with the men in blue,
Where your doctor's khaki's "U. S."

James T. Skinner.

Hospitals for Reconstruction

The Surgeon-General of the Army has taken over Fort Snelling, Minn., Fort Sheridan, Ill., and Fort Benjamin Harrison, Ind., and will convert them into additional general hospitals for the reception of sick and wounded soldiers returned from abroad. They are to be reconstruction hospitals and to fit the wounded for vocational instruction. Each hospital unit will accommodate 1,000 patients.

Examination for Navy Medical Corps

An examination will be held, October 30 and 31, to fill 326 vacancies in the regular Medical Corps of the Navy. The examination will be open only to present members of the Medical Corps, N. R. F., who are between 21 and 32 years of age.

Colonel McCulloch to Prepare Medical History of the War

Col. Champe C. McCulloch, Jr., M. C., U. S. Army, executive officer of the Board for Collecting and Preparing Material for a Medical and Surgical History of American Participation in the European War, has arrived in France, to establish his administration for this purpose. During his absence Lieut.-Col. Casey A. Wood, M. C., U. S. Army, will be in charge of this work in the Surgeon-General's Office.

Promotion of Retired Medical Officers

Senator Shepherd, on September 26, introduced a bill authorizing the President to promote to brigadier-general, retired, those officers of the Medical Department who entered the service of the United States over thirty-five years ago, and who at this time, though retired, are in active duty in war work.

Naval Base Hospital in Scotland

Naval Base Hospital No. 3, commanded by Capt. Charles M. De Valin, M. C., U. S. Navy, which was organized with personnel mostly from Los Angeles, is now located in Scotland, where it occupies a building formerly utilized by the Royal Army Hospital Service. It has accommodation for 625 patients with possibilities of expansion to accommodate 825, and will care for patients in the naval dressing, and the personnel of the British and American Expeditionary Forces.

Physical Qualifications for Medical Service with the Red Cross

We are informed by Dr. Alfred E. Shipley, secretary of the medical advisory committee of the American Red Cross, Washington, D. C., that every individual going abroad, in whatever capacity, in Red Cross work is required to pass a satisfactory physical examination. In the medical division physicians are sometimes accepted for Red Cross work who, because of physcal disqualification, are unable to secure commissions in the Medical Department of the Army. It is appreciated by the Red Cross that such physicians may be used in the medical work among the civilian population abroad as they are not placed under the strain incidental to work in the war areas.

Promotions

The following officers have been promoted from major to lieutenant-colonel: Edward J. G. Beardsley, Philadelphia; Thomas P. Lloyd, Shreveport, La.; James A. Mattison, Hot Springs, S. D.; Joseph Sailer, Philadelphia; Oliver H. Campbell, St. Louis; Bertram F. Alden, San Francisco; Walter W. Crawford, Hattiesburg, Miss.; Jonathan E. Burns, Baltimore; Charles N. B. Camac, New York; William C. LeCompte, Bristol, Pa.; Harry T. Summersgill, San Francisco; Charles H. Schlichter, Elizabeth, N. J.; Edward W. Pinkham, New York; William J. Bell, Washington, D. C.; Warren A. Dennis, St. Paul; Joshua C. Hubbard, Boston; Wiley E. Woodbury, New York; Edmund J. Doering, Chicago; John E. Jennings, Brooklyn; William W. Percy, Rochester, N. Y.; John H. Blackburn, Bowling Green, Ky.; Edmund Moss, New Orleans; Henry R. Brown, Albuquerque, N. M.; Robert Smart, Coronado, Calif.; Herbert H. Smith, Highland, Kan.

Revision Standards of Physical Examination

The office of the Provost Marshal-General has just issued to the draft executives of all states, a revision of Form 75, the Standards of Physical Examination. The changes are few, and are mainly with a view to making available the greater number of registrants having remediable defects (Group B), by transferring them to Group C, for special or limited service. Thus, when inducted and accepted at camps, the defects may be corrected when convenient; meanwhile, the Army will have the benefit of the service of these men.

Registrants who have heretofore, on examination, fallen into Group B (the deferred remediable group) and now, under the revised Form 75, have physical defects placing them in Group C (as physically qualified for special or limited military service), are at once to be reviewed, reexamined if necessary, and recorded in Group C, *subject to call for special or limited military service.*

The next most important change is that which cites certain variations from Army physical standards in the assignment of inducted men to the Navy and the Marine Corps. This states:

5. Navy standards of physical requirements conform in the main to those of the Army included under Group A. But registrants who, on examination, present the following defects, shall not be accepted for service in the Navy or Marine Corps:

Eyes: (A) Vision less than three quarters of the normal in either eye. (B) Color blindness.

Skin: (A) Parasiting affections, including pediculosis, ringworm and scabies. (B) Eczema. (C) Psoriasis.

Genito-urinary organs and venereal diseases: (A) Absence, atrophy or nondescent of both testicles. (B) Venereal disease, any type or stage.

Height: Over 74 inches.

ARMY TO HAVE SPECIAL REGULATIONS

Form 75 pertains only to the Selective Service and will not be issued to the Army. In its stead, the Adjutant-General will distribute to all mobilization points a pamphlet known as Special Regulations No. 65, War Department, which is identical with Form 75 as to physical standards.

DESTRUCTION OF PREVIOUS EDITION

On receipt of the Second Edition of Form 75, old copies of the former edition should be at once destroyed, with the exception of such as are needed to complete permanent reference files.

From a Rookie at Fort Oglethorpe

The following is from a personal letter, and not intended for publication. As Fort Oglethorpe is the first assignment to the great majority of physicians who enter the Medical Corps, a record of the experience of "one of us" will be read with satisfaction.

Got here eight days ago, or perhaps nine—all days are alike now—and am in a good bunch of fellows, from 40 to 54 years old and growing younger visibly day by day. If you ever desire to lose some of your sylphlike rotundity I would prescribe this Greenleaf process of reduction and guarantee results. Everything undergoes reduction here—at once you become a private, reduced from lieutenant, captain, or what not—and down goes all your fancied military glory at one crack. I have learned with due humility to my soul's salvation that there are certain ways inviolate in which to fold blankets, scrub cots, oil floors, fill water buckets, and hang up clothes. Also that to do your own laundry work may be advisable. It's the greatest institution of applied learning in the world and you could not begin to pay me for the experience. I enjoy everything from soup to nuts, including rolling in the clay dirt at 6:15 every morning. By evening that tired feeling assumes enormous proportions and at 9:30 you go to sleep with a bang and are only roused at 4 a. m. or so by the procession of prostatics on their parade to the latrine. This is a community existence applied to every detail of one's daily functions; the monastic soul receives a rude shock at every turn. It's the biggest game that any fellow ever was privileged to join in with, and I am really sorry for those who have missed the chance to go to Camp Greenleaf. Everyone is enthusiastic and full of "pep," and the older men have my unbounded admiration for their gameness. We are kept on the jump from early morning till 9:30 p. m., and have to make use of every interval, for at any moment you may be (and usually are) called out for something or other, usually extra drill, or policing the grounds, or other equally fascinating pursuits.

Because we started a new company and I was one of the first two arrivals, the honorable assignment of Barracks Sergeant fell to my lot, and that means responsibility for the condition of the barracks. It's a sort of masculinized housekeeper's job and with my staff of highly trained assistants (trained in every respect but housekeeping) the setting sun each day finds our work well *done*, but the inspector takes a different view of the matter and isn't a good inspector unless he can find something to criticize, which he always does.

INFORMATION FOR MEDICAL SCHOOLS AND PROGRAM FOR PREMEDICAL STUDENTS

The War Department, Committee on Education and Special Training, has issued a special bulletin relating to the courses to be followed by premedical students:

1. Beginning October 1, terms should be granted in all schools on a quarterly basis, in each term twelve weeks being devoted to instruction and examinations.

2. Members of the Students' Army Training Corps will be under military discipline continuously, and, as soon as proper arrangements can be completed, they will live in barracks as prescribed by the military authorities. A definite schedule of work must be arranged, eleven hours per week being devoted by medical students to practical military instruction (drill, etc.), theoretical military instruction and physical training, and forty-two hours per week to professional instruction, this time including lectures, recitations and supervised study. In the case of students who have pursued for at least one year at an approved institution such studies as form part of the program of preparation for the Medical Corps, the Committee on Education and Special Training may authorize a reduction in the hours of military instruction to not less than six hours provided the reduction is made good by the substitution of a corresponding number of hours in approved medical subjects. (For the schedule for premedical students see 6 and 7, below.) Seniors should enter the Students' Army Training Corps; but it is expected that special

arrangements will be made for those who are serving as interns in hospitals, and possibly for other advanced students —probably by means of furlough.

3. Medical schools are classified as professional schools under the Special Regulations for the Students Army Training Corps (Aa.1, par. 26). The program of studies for these schools is not yet prescribed, but a program approved by the Committee on Education and Special Training will be sent to the schools in the near future. In the meantime the schools should continue their existing programs except for such modifications as may be necessary to introduce military training, and the course in war issues.

4. Students intending to prepare for the study of medicine should register as premedical students.

5. Premedical students must pursue a course that is approved as a premedical course by the Committee on Education and Special Training.

6. A special war issues course is prescribed for all students who are not excused under the following provisions of par. 26, Special Regulations:

"The District Educational Director (Section A—Collegiate Section) may empower colleges to excuse from this course:

"(1) Members of the S. A. T. C. who have had a similar course even though not identical in every detail, or

"(2) Members of the S. A. T. C. who have had at least two years of work of collegiate grade in an approved institution and who should be required to concentrate the whole of their time on advanced studies."

The war issues course is described in Special Descriptive Circulars C.c. 12 and C.c. 13.

7. For the first quarter of the premedical course the following program is prescribed: Inorganic chemistry, twenty-one hours per week; biology, twelve hours per week; war issues, nine hours per week, and military instruction, eleven hours per week. This course corresponds to the course approved for students of chemistry and chemical engineering with the substitution of biology for mathematics. Students in the premedical group may profitably be taught in chemistry in classes together with students taking the chemistry program. The program for the remaining terms of the premedical course will be submitted later. The premedical course will be condensed to cover four terms of twelve weeks each and eleven hours of military instruction will be required.

8. Students who have already pursued the premedical course for one school year should concentrate on chemistry, physics and biology. In each case they should take work in these subjects to the extent needed to meet the present requirements for admission to medical schools in order that they may be prepared to enter on their professional study of medicine as soon as practicable. Second-year premedical students will have eleven hours of military instruction.

9. Those who pursue a course not approved as a premedical course (see sections 4 and 5) will not be regarded as premedical students, and their attention should be directed to General Circular C.a.4.

Committee on Education and Special Training,
By R. C. Maclaurin,
Educational Director, Collegiate Section.

Oct. 3, 1918.

BRIGADIER-GENERAL MUNSON ASSIGNED TO THE GENERAL STAFF

Col. Edward L. Munson, for twenty-five years an officer of the Medical Corps of the Army, has just been promoted to the rank of brigadier-general, and with the promotion selected for duty on the general staff. The new commission is in the line of the Army. General Munson is the third medical officer of the Army to be given general officer's rank for duty outside the Medical Department of the Army, the previous appointees being Generals Ainsworth and Leonard Wood. General Munson has had extensive experience in administrative work, having organized and administered the training system in training camps of the Medical Department, later being placed in command of Camp Greenleaf. Under his direction the medical officers' training camp at Fort Riley was merged with Camp Greenleaf into the greatest training camp for medical men ever organized. General Munson is also known for his textbooks on military hygiene and the work of the medical department in war used as official textbooks by the War Department. As editor of the *Military Surgeon* and secretary of the Association of Military Surgeons he is personally known to many of the officers in the service. He has also devised several articles of equipment adopted by the War Department, notably the tropical service tent, and as president of a board, the present widely known army shoe. He has been twice gold medallist of the Military Service Institution and was twice appointed by the Philippine government as health officer for the Philippine Islands. Recently he submitted a plan to the War Department for the psychologic stimulation of troops in the promotion of fighting efficiency. This method was demonstrated while Colonel Munson was in charge at Camp Greenleaf and caused his selection as an officer of the general staff to carry out the extension of this system throughout the entire Army. General Munson is a native of New Haven, Conn., and a graduate of Yale University, from which he received the degrees of A.B., A.M. and M.D.

Brigadier-General Edward L. Munson

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Personal.—Dr. Lee W. Roe has been elected medical inspector of the schools of Mobile, to succeed Dr. M. Toulmin Gaines, who has resigned to enter the military service.

Home for Antituberculosis Dispensary.—The Birmingham Anti-Tuberculosis Association at its annual meeting announced that it had purchased a permanent home to house a dispensary. The association adopted resolutions of regret on the death of Lieut. Philip M. Kyser, M. C., U. S. Army, and elected officers. Dr. George Eaves was made secretary of the association; Dr. Horace M. Edmonds, Tonawanda, N. Y., a member of the board of trustees, and Dr. Morris Newfield, a member of the executive committee.

CALIFORNIA

Venereal Disease Reports.—For the first six months of 1918 nearly 2,000 cases of gonorrhea were reported to the state board of health under the new venereal disease regulations, and during the same time about 1,500 cases of syphilis. This represents a great improvement in the reporting of these diseases, and it is expected that for the whole year the number of these cases reported will be greater than the number of tuberculosis cases.

Shipyard Sanitation.—California now has an increased number of shipyards and work is being carried on actively. According to the *Bulletin* of the state board of health, sanitary conditions in the neighborhood of some of these shipyards have been bad. A shipyard was built in a marshy district overflowed by tides and consequently a breeding-place for mosquitoes. Mosquitoes were so numerous that they interfered greatly with the work in the shipyard and even compelled the suspension of work at times. This applied also to some of the other shipyards in the state, and it became so serious that the governor was appealed to for aid. He referred the matter to the state board of health, and after investigation, drainage was instituted where possible and standing water covered with oil. At Long Beach this work was done by the local authorities with assistance from Los Angeles, the National Canners' Association and other corporations. The mosquito nuisance has now been abated.

DISTRICT OF COLUMBIA

Railway Surgeons to Meet.—The twelfth annual meeting of the Minneapolis, St. Paul, and Sault Ste. Marie Railway Surgical Association will be held at Hotel Radison, Minneapolis, December 3 and 4.

Personal.—Commander Howard F. Strine, M. C., U. S. Navy, has been appointed associate professor of the principles and practice of medicine in Georgetown University, Medical School, and acting chief of the department of surgery, at the University Hospital, Washington, D. C.

IOWA

Denied New Trial.—Dr. C. Allen Snyder, Dubuque, convicted of murder in the second degree and sentenced to twenty years in the penitentiary, is reported to have been denied a new trial.

Guilty of Disloyalty.—Dr. Walter A. Matthey, charged with bringing Daniel H. Wallace to Davenport to a seditious meeting, July, 1917, is said to have been found guilty on one of two counts. Sentence has not yet been pronounced.

Personal.—Dr. David K. Douthett, Osceola, fractured his right arm while cranking his automobile, October 2.——Dr. E. T. McLaughlin, Knoxville, has started for France where he goes as secretary to the Knights of Columbus.——Dr. William C. Goenne has been appointed city physician of Davenport during the absence of Dr. George M. Middleton, in the military service.——Dr. Max E. Witte has been reappointed superintendent of the Clarinda State Hospital.

MARYLAND

Public Health Service to Aid in "Flu" Epidemic.—The state department of health has announced that the United States Public Health Service will send to Maryland four or five doctors to help out in the counties where many of the local physicians are either ill or overworked because of the influenza epidemic.

The most encouraging feature of the situation which has been alarming public health officers for more than a week was the announcement that the disease appeared to be abating somewhat in the city and state, as well as at the military camps. Information received at the Baltimore City Health Department was that the disease seemed to be lessening its grip on South Baltimore. While the deaths in the city did not show any decrease, there was a slight drop in the number of new cases reported. Dr. C. Hampson Jones, chief of the state bureau of communicable diseases, stated that conditions were generally improved in the counties. Reports to this effect came from Cumberland, Hagerstown, Frederick, and Kent County.

Personal.—Dr. James J. Murphy, chief of staff of the Emergency Hospital, Annapolis, and county health officer for Anne Arundel County, is ill with pneumonia following an attack of influenza. His removal from active practice is a severe blow to the city, whose depleted supply of physicians are overworked in attending influenza cases.——Dr. James H. Mason Knox, Jr., has returned to Baltimore, after a year in France, where he helped organize the work of the Children's Bureau, a part of the Civilian Relief activities of the Red Cross. Dr. Knox paid two visits to the front, one in Belgium and the other to an American sector, during his stay in France.——Drs. William A. Fisher, William S. Baer and George Walker, all of Baltimore, who were attached to the Hopkins Unit, but since have been detached into other branches of the medical service in France, and Dr. Archibald C. Harrison of the University of Maryland unit have received the rank of lieutenant-colonel. Dr. Fisher is chief assistant to Dr. John M. T. Finney; Dr. Baer has been made chief consultant orthopedic surgeon of the American Expeditionary Forces, and Dr. Walker is doing social hygiene work at ports of debarkation of American soldiers.——The many friends of Prof. Thomas S. Cullen of the Johns Hopkins University will hear with regret the news of the recent death of Mrs. Cullen.

MINNESOTA

Health Association Incorporated.—The Minnesota Public Health Association announces in its weekly bulletin, October 3, that the association has been regularly incorporated in the state as an "educational, scientific and benevolent society, not for gain or profit." The incorporators are the present officers, who are Governor J. A. A. Burnquist, president; M. L. Burton, Dr. Warren L. Beebe, St. Cloud; Mrs. A. L. Robinson, Mrs. Mary Brandrup, Drs. Edward L. Tuohy, Duluth; Pearl M. Hall, Minneapolis; George D. Head, Minneapolis; Prof. F. H. Bass, Mrs. W. L. Laidlaw and A. D. Wilson. The annual meetings will be held in November.

MONTANA

State Tuberculosis Society Election.—At the annual meeting of the Montana State Association for the Prevention and Cure of Tuberculosis, September 25, the following officers were elected: president, H. R. Cunningham, Helena; vice presidents, Dr. Oscar M. Lanstrum, Helena, Mrs. S. Sadler, Great Falls, and Otto Simonson, Butte; honorary vice presidents, Governor S. B. Stewart, Harry Yeager, Great Falls, and Roy Alley, Butte; secretary, Mrs. Sarah Morse, Helena, and treasurer, Dr. T. O. Hammond, Helena. The principal addresses were those by Dr. David R. Lyman, New Haven, Conn., president of the National Tuberculosis Association, on "The Rehabilitation and Reconstruction of the Tuberculous Soldier," and by Dr. Charles J. Hatfield, Philadelphia, secretary of the National Tuberculosis Association, on "The Function of the Organized Tuberculosis Forces."

NEW JERSEY

Epidemic Abating.—According to the health board of Gloucester the epidemic is receding and a few days more will find most of the shipyard workers back at work. Seven additional deaths were reported, October 12, making a total of eighty-five. Sanitary squads are inspecting the homes in which cases have occurred and are volunteering their services to clean and disinfect. In Camden there has been a daily decrease in the number of new cases reported. Up to October 12, 5,163 cases had been reported.

NEW YORK

Public Health Nurses Appointed.—The following places have secured appropriations for public health nurses since April 15; Syracuse, Olean, Rensselaer, Dunkirk, Ogdensburg, Tuckahoe, Herkimer, Endicott, Gloversville, Kingston, Hudson, Norwich, Cohoes, Carthage, Greene, Ticonderoga and the Dutchess County Health Association.

New York City

New Naval Hospital in Brooklyn.—A naval hospital which will house 1,200 patients and a nurses' home for 250 nurses is in the process of construction on Flushing Avenue near Emerson Street, Brooklyn. The building is to be four stories high with a floor area of 280 by 200 feet. The cost of the building will be $950,000. The contract calls for the completion of the building within 120 calendar days.

Home for Overseas Nurses.—The New York County Chapter of the American Red Cross opened a temporary home for nurses passing through this city on their way to or from the front, at 11 West Tenth Street, with appropriate exercises on October 10. With more than 1,000 Red Cross nurses always quartered in this city this home will fill a great need in providing rest and recreation for transient nurses.

Outing for Convalescent Soldiers and Sailors.—Special Deputy Police Commissioner John A. Harriss, October 1, acted as host to 150 convalescent sailors from United States war ships on duty in foreign waters and 100 marines who are recovering from wounds received in the fighting around Chateau Thierry. The patients were conveyed by automobiles from various hospitals to Dr. Harriss' steam yacht which took them to his summer home at Collender's Point, Conn., where they were entertained with a concert and a shore dinner.

Influenza in New York.—The records of the health department show that, from September 18 to October 11, 25,082 cases of influenza have been reported with 394 cases of pneumonia. There have been 183 deaths from influenza and 210 from pneumonia during this period. The board of estimate has given the health department $55,000 with which to fight the epidemic. Health Commissioner Dr. Royal S. Copeland has taken the unusual method of calling on the district leaders to use their party machinery to hunt out influenza cases. A statement issued by the Public Health Committee of the New York Academy of Medicine asserts that more vigorous measures should be taken by the health department in its campaign against Spanish influenza, but declares that there is no occasion for undue alarm on the part of the public, as only 2 per cent. of the population has been affected thus far. The committee strongly endorses the educational campaign being carried on by the health authorities here and elsewhere, and predicts that the epidemic will begin to decline in from two weeks to a month. Precautionary measures are recommended, many of which the health department is already enforcing. The most serious phase of the situation is the shortage of nurses. It is said that 5,000 nurses are needed at once. To meet this demand a Nurses' Emergency Council has been formed through which the Red Cross is making a house to house canvass for women with nursing knowledge. Reports from the state board of health show that, October 10, there were 31,217 cases of influenza in the state. The state laboratory is preparing an anti-influenza serum which will be ready for distribution in a few days.

OKLAHOMA

Personal.—Dr. Albert C. Hirshfield, assistant city physician of Oklahoma City, is said to have resigned.——Dr. Nelson P. H. White, Clinton, was seriously injured when his automobile was struck by a train at a grade crossing, 3 miles east of Clinton.——At a recent meeting of the state medical board of Oklahoma City, Dr. B. L. Denison, Garvin, was elected president.

Tuberculosis Conference.—The annual meeting of the Oklahoma Association for the Prevention of Tuberculosis and the State Public Health Conference was held in the Chamber of Commerce, Oklahoma City, September 24. Two hundred delegates were present, and the following officers were elected: president, E. K. Gaylord, Oklahoma City (reelected), honorary vice president, Dr. John W. Duke, Guthrie (reelected); vice presidents, Drs. Lewis J. Moorman, Oklahoma City, Mr. John Moffitt, Muskogee, Mr. John Woodward, Tulsa, and Mr. John W. Sunder. It was voted to change the name of the association to the Oklahoma Tuberculosis Association.

PENNSYLVANIA

Epidemic in Schuylkill County.—According to a special telegram to the *Public Ledger* on October 12, there were 11,000 cases of influenza in Schuylkill County, of which 1,600 were in Pottsville. Many physicians from other localities, making a total of seventy, were getting the situation in hand. In addition fifty physicians have been ordered there from the U. S. Medical Corps at Allentown. In Minersville the epidemic raged among the foreign born population and a number of men from the United States Medical Corps were ordered to take charge there. Coal production in this place has been greatly curtailed.

Philadelphia

Governor Appeals for Nurses.—October 11, Governor Braumbaugh issued a proclamation calling on nurses to volunteer their services during the influenza epidemic, especially nurses engaged as companions in the homes of the wealthy.

Influenza Epidemic.—Lieutenant-Commander Plummer, surgeon in charge of the Fourth Naval District, in which the first cases of epidemic influenza appeared in this city, reported, October 11, that the district was practically cleared of the disease. There were but twenty-six cases of influenza and three of pneumonia, of these only sixteen were within the district, the other ten having been taken from arriving ships. A chart in the surgeon's office shows that the epidemic began in the district on September 12, the peak was reached September 18 and that there was a steady decline since that date. The death rate for the week ending October 12, in Philadelphia was the highest ever recorded—3,234, of which 2,635 were caused by influenza and pneumonia. The highest death rate of any previous week was 1,191 on October 5, when the death rate was 35.26 per thousand. The rate for the week just passed reached 95.74 per thousand. Five nurses have died from influenza at the Philadelphia General Hospital since October 8.

Personal.—Dr. Cyrus L. Stevens, Athens, the president elect of the Medical Society of the State of Pennsylvania, who was stricken with pneumonia during the convention of the Medical Society, in this city, is convalescing at the University Hospital.——Dr. Elmer G. Whinna has just completed twenty-five years of continuous service as physician-in-charge of the Philadelphia Home for Infants.——Drs. Isaac F. Stover, Philadelphia, and Louis Weinstock, New York, are recovering from pneumonia. Dr. Stover is outside physician of the Germantown almshouse.——Dr. James F. Carrell is recovering from influenza at the St. Joseph's Hospital.——Dr. Donald Guthrie, chief surgeon at the Packer Hospital, Sayre, Pa., is in the University Hospital suffering from pneumonia following influenza.——Dr. Harrington S. Dickinson has been appointed assistant school medical inspector.——Dr. James M. Anders, who has been ill with influenza, has recovered.——Dr. Eugene Swayne, Bristol, who mysteriously disappeared last week, returned to Bristol, October 11. He had been working among influenza patients for a number of days and had gone to Philadelphia for a conference, collapsed on the train and was taken to the Frankford Hospital, where he was unconscious for four days before his identity could be determined.

UTAH

New Officers.—At the twenty-fourth annual meeting of the Utah State Medical Association held in Salt Lake City, September 10 and 11, Dr. George W. Middleton, Salt Lake City, was elected president and Dr. William L. Rich, Salt Lake City, secretary.

Personal.—Dr. Harry N. Mayo, Salt Lake City, has resigned as a member of the state board of medical examiners to enter the military service.——Major Walter C. Chidester, M. C., U. S. Army, has been assigned to duty as chief of the surgical staff of the reconstruction hospital, Fort Douglas.

VERMONT

Personal.—Dr. John H. Woodruff, Barre, has been appointed medical aide to the governor of Vermont, to succeed Dr. John B. Wheeler, Burlington, who has resigned.——The Caledonia County Medical Society gave a farewell dinner at St. Johnsbury for Lieut. Robert H. Burke, who has been ordered to Camp Upton, and presented him with a wrist watch and a masonic ring.——Dr. Fremont Hamilton, Brattleboro, was seriously injured by the overturning of his automobile, August 31.——Dr. Chester M. Ferrin, Burlington, has been elected Surgeon-General of the Grand Army of the Republic.

WASHINGTON

Hospital at University.—A plan to build a hospital on the campus of the University of Washington, Seattle, to cost a million dollars and which is to form the nucleus for a medical department of the university, was proposed and endorsed at the meeting of the Kings County Medical Society.

Law Violators.—Dr. William G. Emonds, Seattle, is reported to have been found guilty, September 24, of issuing a prescription for liquor. He is said to have been convicted twice in 1916, and once in 1918, of unlawfully issuing prescriptions for liquor.——Dr. Thomas R. Loer, Seattle, is said to have been found guilty of unlawful issuance of prescriptions, September 6, and to have been fined $200.

WISCONSIN

State Society Meeting.—At the seventy-second annual meeting of the State Medical Society of Wisconsin, held in Milwaukee, October 2 to 4, the following officers were elected: president-elect, Dr. Dennis J. Hayes, Milwaukee; vice presidents, Drs. J. Sothoran Keech, Racine, Luther A. Potter, Superior, and Herman Gilbert, Madison; Councilor for the first district, Dr. Hoyt E. Dearholt, Milwaukee; member of the committee of public health and instruction to succeed Dr. John M. Beffel, Milwaukee, Dr. William H. Washburn; delegate of medical education, to succeed Dr. Louis M. Warfield, Dr. Louis F. Jermain, Milwaukee; delegates to the American Medical Association, Drs. Horace M. Brown, Milwaukee, and L. Rock Sleyster, Waupun; alternates, Dr. John F. Pember, Janesville, and Louis F. Jermain, Milwaukee, and acting councilor for the seventh district, during the absence of Dr. Edward Evans, in France, Dr. Wilbur T. Sarles, Sparta.

CANADA

Influenza.—The influenza has seized Montreal, Ottawa, Toronto, Hamilton, and other Canadian cities in a firm grip. Hotels are being turned into improvised hospitals in Toronto for the accommodation of patients, the hospitals being filled to overflowing. There is a great demand for nurses, not only among soldiers but among civilians. Many deaths have been reported, particularly from pneumonia.

GENERAL

Meeting of American Public Health Association.—At the request of the Surgeon-General of the U. S. Public Health Service, the Officers of the American Public Health Association announce the postponement of their annual meeting, which was to have been held in Chicago October 14-17, to December 9-12, at the same place. This action was deemed advisable especially because it was considered unwise to ask sanitarians to leave their posts under present health conditions.

Cancellation of Meeting of Clinical Congress of the American College of Surgeons.—Information has been received, under government frank, that "owing to the influenza epidemic prevalent throughout the country and the resultant increased demand for the services of doctors in their home communities, it has been considered advisable by the executive committee of the General Medical Board to cancel the meeting scheduled to be held in New York City at the Waldorf Astoria, October 20. The regular annual session of the Clinical Congress of the American College of Surgeons, arranged for the week beginning October 21, has been cancelled for the same reason."

FOREIGN

Austria Forbids the Export of Drugs to Hungary.—Austrian telegram advices from Vienna state that Austria has forbidden the exportation of pharmaceutical supplies to Hungary. The Hungarian government has, therefore, been compelled to confiscate all supplies that are found in pharmacies.

Personal.—Dr. Maurice F. Egan, formerly American minister to Denmark, had bestowed on him the grand cross of the Order of Dannebrog by King Christian.——Dr. William White, Pittsburgh, has been placed in charge of the Italian Tuberculosis Unit, recently organized by the American Red Cross.

Collective Inquiry on the By-Effects of Arsphenamin.—The *Hospitalstidende* quotes a German weekly to the effect that so many reports have been made on by-effects from arsphenamin that a Cologne medical society, the Allgemeine ärztliche Verein, has appointed a committee to collect data on the subject. The German Dermatologic Association is represented on the committee by Professor Hoffmann, and physicians in general are asked to report all instances of by-effects in their practice to the committee, Rudolfplatz 3, Köln.

Deaths in the Profession Abroad.—Dr. M. Jatta, of the Italian Public Health Service, in charge of the campaign against malaria in the province of Puglia.——Dr. F. Arena, professor of chemical analysis at the University of Naples.——Dr. F. Jeannel, dean and professor of surgery at the University of Toulouse, aged 68, author of numerous articles on surgery and of a manual on surgery of the intestines.——Dr. E. Fraenkel, a prominent Danish practitioner of the Slagelse province.——Dr. J. R. Semprun, professor of clinical neurology at the University of Buenos Aires, senator, consejero de la Facultad de Ciencias Medicas, director of the Asistencia Publica, and president of the Comision Nacional de Bellas Artes, in addition to his work as chief of the Hospital Muñiz and detention hospital.

"New and Nonofficial Remedies" in France.—The *Paris médical* now falls into line with some other French medical periodicals in describing for its readers the work and ideals of the Council on Pharmacy and Chemistry and the book "New and Nonofficial Remedies." It reproduces entire Professor Puckner's letter on the subject to the *Journal de pharmacie et de chimie* relating that he had followed with interest the recent discussion in the Académie de médecine relative to regulating the sale of proprietaries. A whole page in the *Paris médical* is devoted to a translation of the preface to N. N. R., and the fact is emphasized that of all the proprietaries indexed only five or six are of French origin while over half of them are of German production. A previous notice of the kind was summarized in The Journal, June 8, 1918, p. 1783.

In Honor of Cortezo.—The director of the *Siglo Medico*, Excmo. Señor Don Carlos Maria Cortezo, has been a prominent figure in medical and political circles in Spain for many years, and has occupied high posts in the state, minister of public instruction, senator, etc. As already mentioned in these columns, the highest center of national culture, the Academy of Language, recently elected him to membership, and his friends on this occasion have opened a subscription for the purpose of offering him, it is said, "a homage worthy of his name and high position." The treasurer of the fund is Dr. J. Sarabia, Velasquez 5, Madrid. The dean of the medical department of the University of Madrid, Professor Recasens, initiated the movement in appreciation of Cortezo's constant efforts to promote the moral and material welfare of the profession, and particularly for his plan for the support and education of the orphans of physicians, the new Colegio de Huerfanos at Madrid.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Fiftieth Professional Anniversary of Uribe.—On the initiative of the medical society of Medellin, Colombia, the profession throughout the whole country, Colombia, joined in doing honor to Dr. F. A. Uribe of Medellin on the occasion of his "golden wedding with science." He is a member, with three other physicians, of the senate of the republic. The lower house has about fourteen medical members.

Medical Society and Journal of Northern Brazil.—In 1899 the physicians of northern Brazil organized the Sociedade de Medicina e Pharmacia do Amazonas, and founded the *Revista Medica do Amazonas.* Neither the society nor its journal lasted more than a few months, but ten years later the *Amazonas Medico* was founded. This, too, survived only for ten issues. The medical organization was revived last year, and it has now started anew the publication of the *Amazonas Medico,* and both seem to be entering on an era of successful and fruitful work. The *Amazonas* starts on its second phase as a quarterly, under the editorial supervision of Drs. A. da Matta, J. de Moraes and four others. An appeal for exchanges is printed in seven languages: Address Caixa Postal 40 A, Manaos. The first issue is indexed in the Current Literature Department.

CORRECTION

Captain Morehouse Living.—The Journal last week carried the report of the death of Capt. Cecil Goodard Morehouse, Waukon, Iowa. We are informed that a cablegram received by Mrs. Morehouse states that Captain Morehouse was severely wounded on July 16, but recovered and is now at work again.

MEXICO LETTER

Mexico City, Sept. 23, 1918.

Popular Scientific Lectures

The alumni of the Escuela Medico Militar have organized a series of lectures on scientific subjects to be delivered by the professors of the school. They are held in the hall of the National Museum, and the three that have already been delivered have been very well attended. One was by Dr. E. Cervera, professor of bacteriology. His subject was "The Therapeutics of Yesterday and Today." Dr. E. Ramirez, professor of medical chemistry, spoke on the present status of medical science, and Sr. I. Ochoterena, professor of histology, on the relations between comparative neurology and human psychology.

Friends of France

A society has been organized among the leading intellectuals of the country. It is called the Amigos de Francia, and includes Dr. E. G. Martinez, physician and poet, who is president of the society, Dr. C. Barajas, author; Dr. J. Urueta, former minister of foreign affairs; Dr. L. M. Rojas, director of the daily paper, the *Universal;* Dr. F. Canale; D. C. D. Dufoo, economist; Dr. M. Flores and E. Pallares, journalists; Dr. A. Pruneda, director of the Escuela Nacional de Comercio, Lic. J. S. Azcona, and a number of others.

The Blind

A committee of which Dr. J. Terres is president has been organized to prevent the spread of blindness and to ameliorate the condition of the blind. It has inaugurated its work by publishing articles in the daily papers to enlighten the public on the dangers of smallpox as a frequent cause of blindness, and the necessity for warding it off by vaccination and revaccination. The importance of using exclusively animal vaccine for the purpose has been emphasized, as this eliminates the possibility of inoculation with syphilis by this means (since unfortunately even yet some physicians employ humanized vaccine). Instructions were also given how vaccination should be done correctly. The committee announced further that it will present tubes of vaccine lymph to all who apply.

The Homeopaths Appeal

The governor of the state of Puebla has issued a decree prohibiting the practice of medicine to the homeopaths in that state, as there they are generally very ignorant persons. They appealed to the district judge, alleging that the governor's order violated their constitutional rights. The judge denied their appeal, and they have carried their appeal to the supreme court of the nation. This high tribunal has not yet handed down its decision in the matter.

Quadruplets

The wife of a citizen of Merida, in Yucatan, was recently delivered of four children at one birth, three boys and one girl. Mother and children are in the best of health, according to the local papers.

Quarantine Against Guatemala

The Departamento de Salubridad has been officially informed that yellow fever has disappeared from the state of Guatemala, where there have been cases during the last months. An official survey is to be made at once to verify this notice so that the quarantine between Guatemala and Mexico can be suspended, as it materially hampers commerce between the neighbor countries.

Bazaar for Hospital

A *kermesse* was organized, September 15, for the benefit of the American Hospital. It was held in the halls of the Eliseo, founded by the United States colony, in this city. It was crowded with citizens and subjects of the Allied nations and leading members of Mexican society, and a large amount was collected for the improvements needed at the hospital.

Influenza

About 50 per cent. of the sailors on the Argentine man of war at present in Vera Cruz waters, and those that had come to this city for a visit have been affected with influenza, but fortunately it has been mild to date. It is remarkable that among the inhabitants of the city influenza has not assumed an epidemic character. The epidemic among our Argentine guests is ascribed to the influence of the altitude of the city and the relative drop in temperature noted at this time of the year. The sailors affected were isolated and properly cared for

PARIS LETTER

Paris, Sept. 26, 1918.

Antidysentery Measures

A number of cases of dysentery, several of which terminated in death, have occurred in Paris, and in the *département* of the Seine. In order to avoid a spread of the disease, the prefect of police has asked the people to conform strictly to certain regulations, such as, to use only milk that has been boiled for at least five minutes; not to put ice in any drinks; to protect food from flies, which should be destroyed in every possible way.

Biology of War

The Société de biologie has arranged to hold a series of meetings devoted to discussion of the biology of war. These meetings will be held monthly. The first meeting will take place October 19 and will be given over to the discussion of shock and anesthesia during shock. At the second meeting will be considered infection in the army, and antiseptics at the third.

Brazilian Medical Mission

An important Brazilian medical mission has arrived in Paris. It consists of 180 persons and is in charge of Dr. Nabuco de Gouvea, deputy. The physicians composing the mission will go to the various French hospitals where they will remain until the Brazilian hospital of 500 beds has been completed in the war zone. Dr. de Gouvea has under his direction eight general *chefs de service,* sixteen *chefs d'infirmeries* or *laboratories,* and forty-one *auxiliaires* for the surgical service proper. The pharmacy staff consists of a *chef de service* with two assistants and three *auxiliaires.* There is also a *service d'intendance,* or clerical force. A corps of nurses and a section of the navy sanitary (medical) corps accompany the mission.

Workshop for Franco-American Wounded Soldiers

In Paris there is an *atelier du blessé franco-américain* (at the Grand Palais) where wounded soldiers and the invalided, as well as men on furlough may find employment that is both remunerative and suitable for them. The government, appreciating the work done since the beginning of the war, by Madam Nicolas Eliasco, who is in charge of *l'Atelier du blessé franco-américain,* has conferred on her the medal of the "Reconnaissance française."

A New French Red Cross Stamp

The postal department has on sale a new French Red Cross stamp. On one side of this stamp is the picture of a nurse against a background of ruins, from which unfortunate refugees are being taken by an automobile ambulance. On the other side is a small boat carrying to the hospital ship wounded and sick soldiers who are being brought back from the Orient.

LONDON LETTER

London, Sept. 10, 1918.

A State Medical Service

In recent years much socialistic legislation has taken place, particularly in regard to matters of health. The outstanding instance, for example, is, of course, the insurance act. As pointed out in previous letters, this act is certain to be developed in many directions. Its defects, such as the failure to provide for specialist advice or hospital treatment, are indisputable. About three fourths of physicians are on its panels and therefore are part-time state officials. The burning question now is whether whole-time physicians should be employed. Advanced social reformers are strongly in favor of this proposal, but it is not acceptable to any except a small socialistic minority of the medical profession. The great changes brought about by the war are being used as an argument in favor of the proposal. It is said that our vast armies are well cared for by a state medical service and that when the physicians return to civil practice they will have been admirably trained for a similar service. Moreover, many who in consequence of their patriotism have sacrificed their practices will thus be provided for. Though not officially announced, there is reason to think that a scheme for a whole-time medical service has already been drawn up whereby there are to be five classes corresponding with army ranks: Class 5, lieutenant; Class 4, captain; Class 3, major; Class 2, lieutenant-colonel, and Class 1, colonel. The commencing pay for the fifth class, equal to the lieutenant, is $2,000 a year, with promotion to the fourth class at $2,500, third class at $3,750, second class at $5,000 and first class, equal to the full rank of colonel, $7,500 a year. The second and first classes will remain at these amounts, but for the lower classes there will be yearly increments, for the fifth class of $75 a year until a maximum of $2,500 is reached, and for the fourth class a rise of $125 a year until the third, or major's, class, when the annual increase will be $250 a year, till $5,000 is reached. A novel feature of the scheme is that promotion can be obtained from one class into another only by examination. Thus, unless he passes an examination, the fifth class man will never get above his $2,500 a year. There must be four years interval between the fifth and fourth classes and eight years between both the fourth and third, and the third and second, from which will be chosen the highest class at $7,500 a year. There will be no necessity for a vacancy to exist before a man can qualify for a higher class and pay, at any rate up to the third or major class. The higher classes will deal chiefly with administrative work and with the giving of consultative advice. There will be no expenses to be paid out of the physician's salary; everything—drugs, appliances, clinics and traveling expenses—will be paid for by the government. Men will be expected to look after the health of between 2,000 and 3,000 persons. It will not be necessary to live in the big houses at present in vogue. Any sized house and in any adjacent locality will do, as long as it has telephonic communication. On the argument that either a patient is fit for work or unfit so he will be expected to attend at the office in the morning, evening consultations will be discontinued, and fewer visits paid than is the case at present. Work out of hours, that is to say, after 5 o'clock, will be taken by the juniors, who will take duty in rotation. Localities will be mapped out with exact boundaries, and in those areas all residents, whether rich or poor, will be entitled to medical benefit. All hospitals will be taken over by the government. There will probably be no compensation for the capital value of practices except in cases of unusual hardship; but those entering the scheme will have at 60 pensions, equal to two thirds of their salary, though perhaps they may go on practicing after that date. As a beginning, men who have been in practice for many years and are otherwise qualified will be enabled to enter the service at a higher class than the lowest. Full consultant and specialist services will be provided; men will be appointed to them after taking a special course and passing an examination in the particular work. They will receive higher pay. Study leave up to six months will be granted. Holiday leave will be the same as in the civil services—a month each year. All local lay control will be done away with, the service being under a central board of commissioners consisting of: (1) members appointed by the government from outside the medical profession; (2) members appointed by the government from men at the head of the medical profession, and (3) members elected by those medical men serving in the scheme.

One organized body of physicians, the Medico-Political Union, which principally consists of panel physicians (indeed, it was originally formed by them and then termed the Panel Medico-Political Union) is strongly opposing the scheme. The union was formed because the British Medical Association was not considered sufficiently representative of panel interests and its action not all that could be desired. It may be remembered that at the time of the passing of the insurance act the association was divided into two camps, for and against the act, and considerable ill feeling was aroused that has not entirely subsided. Unlike the association, the Medico-Political Union is registered as a trade union. It thus has the advantage in case of a medical "strike" that its members can interfere with those that do not strike without being open to a charge of "conspiracy," "wrongfully inciting" others to leave their employment and of "libel." Moreover, its accumulated funds cannot be attached. The union is opposed to the whole-time medical service on the grounds that: 1. The most intimately human of all professions enters into confidences in every phase of family life that would not be possible in the case of a paid official. 2. Free choice of physician (a strong point under the insurance act) would no longer be possible and the incentive of fair competition would be abolished, allowing the slowest mover to set the pace. 3. The pay, though excellent and attractive for newly qualified physicians, is not sufficient for experienced ones. 4. Any scheme brought forward with the hope of enlisting the support of physicians should compensate for the capital value of their practices.

Interallied Food Control

Conferences have taken place between the food controllers of America, France, Great Britain and Italy with the object of organizing an interallied food council. A wheat commission sits in London which buys in America, Argentina, Australia and India, thus abolishing competition in neutral markets. It is intended to establish three other commissions, for meat and fats, oil-yielding grains, and sugar. The council intends to form reserves of cereals in America and Europe to guard against bad harvests. Our food controller has recently issued an order regulating the use of wheat, rye, barley and dredge corn for the feeding of animals. Grain fit for human consumption must not be given to animals; grain unfit for human consumption can be so used only under license, except in the case of small quantities not exceeding 10 hundredweight.

Lectures on Shell Shock and War Neuroses

A course of instruction in shell shock and war neuroses, open to all medical officers of the British and American services and to civilian physicians is being given under the sanction of the War Office at the Maudsley Neurological Clearing Hospital, Denmark Hill. Applications for admissions are to be made to Brevet Lieut.-Col. F. W. Mott, M.D., F.R.S. The course consists of daily instruction and practice in the diagnosis and treatment and systematic lectures and demonstrations twice weekly. These are on: 1. The anatomy, physiology and pathology of the nervous and muscular systems applied to the diagnosis, prognosis and treatment of shell shock and war neuroses. 2. The physiologic and pathologic conditions underlying shock—emotional, commotional and surgical. 3. The methods of examining cases of functional nervous disorders (hysteria, neurasthenia and psychoses) and the determination of fitness for military service. 4. The methods of differential diagnosis of organic and functional disease and the combined condition. 5. The diagnosis of conscious simulation (malingering), unconscious simulation and exaggeration. 6. The general principles of treatment of functional diseases of the nervous system. 7. General aspect of the surgical side of neuromuscular disabilities. 8. General principles of psychology as applied to war neuroses and shell shock.

Another American War Hospital in Great Britain

The American Navy has taken over another hospital, which is established in the East Coast of Scotland. The American staff consists of twenty-two medical officers, sixty-three nurses, paymaster, clerical staff, orderlies and artisans. It was organized at Los Angeles by Dr. Rea Smith, surgeon, U. S. Navy, and the commanding officer is Dr. C. M. Devalin, U. S. Navy. The equipment has been brought from America. The hospital will receive not only Americans but also British patients from both the army and the navy.

Marriages

Lieut. Lee Franklin Turlington, M. C., U. S. Army, Birmingham, Ala., on duty at Camp Greenleaf, Fort Oglethorpe, Ga., to Miss Olivia Johnston White of Lynchburg, Va., September 17.

Lieut. Maurice Raschbaum, M. C., U. S. Army, New York City, on duty at Camp A. A. Humphreys, Accotink, Va., was married to Miss Justine Todd of New York City, March 27.

Lieut. Robert Byron Giles, M. C., U. S. Army, New York City, to Miss Fredericke Kröger of Spuyten Duyvil, New York City, September 12.

Lieut. Vivian John Neale, M. C., U. S. Army, to Miss Helen Theresa Douaire, both of Chicago, at Des Moines, Iowa, September 11.

George William Schaefer, Bridgeport, Ohio, to Miss Corynne Price Bush of Wheeling, W. Va., at Columbus, Ohio, August 29.

Lieut. Commander Howson White Cole, Jr., M. C., U. S. Navy, to Miss Mary Constance Wiggins, at Brooklyn, September 9.

Lieut. Raymond Williams Lewis, M. C., U. S. Navy, to Miss Alice Gregory Cragin, both of New York City, October 3.

Charles J. Stambaugh, Reidsville, Pa., to Miss Florence P. Newton of Lewistown, Pa., at Harrisburg, September 25.

Frederick Conrad Schadt, Williamsburg, Iowa, to Miss Louise Setzer of Middle Amana, Iowa, recently.

Claude Vernet Davis, Cleveland, to Miss Laura Sheridan of Connellsville, Ohio, September 21.

Deaths

Capt. Lorenzo Burrows, Jr., M. C., U. S. Army, Buffalo; College of Physicians and Surgeons in the City of New York, 1889; aged 51; a Fellow of the American Medical Association and the New York Academy of Medicine; ophthalmologist to the Buffalo General Hospital; a specialist in diseases of the eye; on duty with Buffalo Base Hospital No. 23; who had been in France since October, 1917; died from pneumonia, September 17.

Died in the Service
IN FRANCE
Capt. Lorenzo Burrows, Jr., M.C., U. S. Army, 1867-1918

Lieut. Arthur Lewis Beyerlein, M. C., U. S. Army, Chicago; University of Illinois, Chicago, 1912; aged 30; a Fellow of the American Medical Association; who was in the government service in the Canal Zone from 1910 to 1916, and was later on duty in the orthopedic department of the Walter Reed General Hospital, Washington, D. C.; died in that institution, October 10, from bronchial pneumonia, following influenza.

John T. Gilmour, Toronto, Ont. (license, Ontario, 1876); aged 63; for nearly twenty years warden of the Ontario Reformatory for Men; an active member and once president of the American Prison Association, and later parole commissioner for the provincial penal institutions; one of the best known administrators of penal institutions of America; died suddenly at his home, July 29, from heart disease.

Act. Asst. Surg. Charles B. Gruver, U. S. P. H. S., Waco, Texas; formerly of Rosman, N. C.; University of Maryland, Baltimore, 1902; aged 40; a member of the Medical Society of the State of North Carolina; at one time president of the Stroudsburg (Pa.), board of health; a member of the staff of the health department of Waco; died in a sanatorium in that city, October 7, from pneumonia.

Ludson Worsham, Evansville, Ind.; New York University, New York City, 1879; aged 63; a Fellow of the American Medical Association; surgeon of the Alaska Commercial Club from 1882 to 1884; chief surgeon of the Evansville and Terre Haute, and Evansville and Indianapolis railroads since 1896; at one time councilman at large; died at his home, September 29, from pneumonia.

David L. Haight, New York City; College of Physicians and Surgeons in the City of New York, 1864; aged 79; a member of the United States Sanitary Commission in 1862, and during the remainder of the Civil War assistant surgeon at the Douglas Hospital, Washington, D. C.; died at the Rockaway Country Club, Cedarhurst, L. I., September 30.

Lieut. Justin A. McCarthy, U. S. N. R. F., Lawrence, Mass.; Jefferson Medical College, 1918; aged 25; a Fellow of the American Medical Association; who came to New London, Conn., to assist in the treatment of influenza at the base hospital, died at the local hospital, New London, September 27, from pneumonia, following influenza.

Clinton E. Stark, Norwich, Conn.; New York Homeopathic Medical College, New York City, 1878; aged 64; once president of the Connecticut State Homeopathic Medical Society; a member of the board of trustees of the Norwich State Hospital since its institution; died at his home, September 26, from pneumonia, following influenza.

Russell H. Dean, Jacksonville, Fla.; Tulane University, New Orleans, 1875; aged 63; once vice president of the Florida Medical Association and president of the Duval County Medical Society and of the Lake County (Fla.) Board of Health; died at his home, September 28, from cerebral hemorrhage.

Theodore Fessler, Portland, Ore.; University of Oregon, Portland, 1904; aged 47; at one time a Fellow of the American Medical Association; great sachem of the Independent Order of Red Men for Oregon in 1911; died in the Good Samaritan Hospital, Portland, September 27, after a surgical operation.

Capt. Charles Alton Sturtevant, M. C., U. S. Army, Manchester, N. H.; Boston University, 1899; aged 43; a Fellow of the American Medical Association; medical officer of the Seventy-Fourth U. S. Infantry; died at Camp Devens, Ayer, Mass., September 24, from pneumonia, following influenza.

Asst. Surg. Hadley Howard Teter, Lieutenant (Junior Grade), U. S. Navy, Cleveland; Ohio State University, Columbus, 1916; aged 27; is reported to be one of the missing from the *U. S. S. Tampa,* which was torpedoed in foreign waters, September 26, while escorting a convoy.

Orion Vassar Wells, Westford, Mass.; Harvard Medical School, 1906; aged 37; a Fellow of the American Medical Association; first lieutenant, M. C., Massachusetts State Guard, and assigned to duty with the Nineteenth Infantry; died at his home, October 4, from pneumonia.

Edward Hastings Wiswall, Wellesley, Mass.; Boston University, 1887; aged 57; for five years assistant physician at the Westboro Insane Hospital; superintendent of the Wellesley Sanitarium; a member of the local school committee for twelve years; died at his home, October 7.

Arthur Kraft Petery, Norristown, Pa.; Medico-Chirurgical College of Philadelphia, 1908; aged 32; a Fellow of the American Medical Association; a member of the staff of the Norristown State Hospital; died in that institution, October 2, from pneumonia, following influenza.

Robert E. Moss, Riverside, Calif.; Marion-Sims College of Medicine, St. Louis, 1897; aged 45; a member of the Medical Society of the State of California, and president of the Riverside County Medical Society; died at his home, September 27.

Lieut. Pressly Robinson Brown, M. C., U. S. Army, Swepsonville, N. C.; North Carolina Medical College, Charlotte, 1914; aged 34; a Fellow of the American Medical Association; is reported in the *Official Bulletin* of July 15 to have been killed in action in France.

Died in the Service
IN FRANCE
Lieut. Pressly R. Brown, M. C., U. S. Army, 1884-1918

Capt. Philip John Keizer, M. C., U. S. Army, North Bend, Ore.; University of Oregon, Portland, 1914; aged 32; a Fellow of the American Medical Association; assigned to duty with the Thirtieth U. S. Engineers; was killed in action in *France,* in line of duty, July 13.

William Binder Shick, Philadelphia; Jefferson Medical College, 1907; aged 39; a Fellow of the American Medical Association; a specialist of diseases of the ear, nose and throat; surgeon to the Jewish Hospital; died, October 3, from pneumonia, *following* influenza.

Elbert Ellsworth Heaton, Lancaster, Mo.; *formerly* of Centerville, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1896; aged 46; is reported to have died in his office, October 4, from a gunshot wound, self-inflicted, it is believed, with suicidal intent.

George Wells, Annapolis, Md.; College of Physicians and Surgeons in the City of New York, 1867; aged 74; for several years chief of the medical staff of the Annapolis Emergency

Hospital; clerk of the court of Anne Arundel County; died at his home, September 29.

George A. Jennings, Burlington, N. J.; Baltimore Medical College, 1902; aged 46; a member of the Medical Society of the State of New Jersey; athletic director of the public schools of Burlington; died, September 30, from pneumonia, following influenza.

William Armstrong DeWitt, Blossburg, Pa.; University of Pennsylvania, Philadelphia, 1908; aged 32; a Fellow of the American Medical Association; chief surgeon of the Blossburg State Hospital; died at his home, October 1, from pneumonia.

Lieut. Philip Melton Kyser, M. C., U. S. Army, Birmingham, Ala.; Vanderbilt University, Nashville, Tenn., 1910; aged 30; a Fellow of the American Medical Association; on duty at Camp Lee, Va.; died in that place, recently, from pneumonia.

Lieut. John Riley Lewis, M. C., U. S. Army, Gainesville, Texas; Fort Worth (Texas) University, 1912; aged 31; a Fellow of the American Medical Association; on duty at a training camp in Long Island, N. Y.; died at the camp, September 25.

Thomas Francis Leen, Boston; Harvard Medical School, 1901; aged 43; a Fellow of the American Medical Association; a specialist in internal medicine; formerly a member of the Boston school committee; died at his home, September 16.

Ernest Albert D. Watson; Pittsburgh; Howard University, Washington, D. C., 1909; aged 40; a colored practitioner, born in Jamaica, British West Indies; died at the West Penn Hospital, Pittsburgh, September 18, from acute nephritis.

Hyman Cohen, Boston; Harvard Medical School, 1918; aged 25; attached to the second medical service of the Boston City Hospital; died in that institution, September 30, from pneumonia, following influenza.

John R. Cross, Buxton, Iowa (license, Iowa, years of practice, 1886); aged 63; at one time a Fellow of the American Medical Association; was killed, October 1, in a grade crossing accident at Hamilton.

Max Maurice Fladen, New York City; University and Bellevue Hospital Medical College, New York City, 1909; aged 32; died at his home, September 30, from pneumonia, following influenza.

Charles Vinton Mathewson, Plainfield, N. J.; Harvard Medical School, 1878; aged 65; who retired several years ago to engage in the insurance business; died at his home, September 20.

Omar Perlie Badger, Boston; Harvard Medical School, 1918; aged 29; an intern in the Boston City Hospital; died in that institution, September 30, from pneumonia, following influenza.

Joseph Warren Tillson, Cohay, Miss.; University of Tennessee, Nashville, 1899; aged 44; a Fellow of the American Medical Association; died at his home, June 10, from heart disease.

Alexander Murdoch Polk, Winthrop, Wash.; Jefferson Medical College, 1887; aged 55; formerly a practitioner of Conconully, Wash.; died at his home, September 18, from heart disease.

William R. Black, Bolivar, Ohio (license, Ohio, twenty-eight years practice, 1896); aged 71; mayor of Bolivar; a veteran of the Civil War; died at his home, September 21.

John R. MacDaniel, Arkadelphia, Ark.; Jefferson Medical College, 1867; aged 78; also a druggist; died at his home, September 18, from cerebral hemorrhage.

John Flood, Chicago; Bennett Medical College, Chicago, 1873; Rush Medical College, 1889; aged 68; died at his home, September 28, from pneumonia.

Benjamin F. Severns, Marion, Ohio; Eclectic Medical Institute, Cincinnati, 1886; aged 69; died at his home, September 24, from cerebral hemorrhage.

George Roy Heaton, Rock Mart, Ga.; Atlanta (Ga.) School of Medicine, 1911; aged 31; died at his home, September 21, from [illegible] e of poison.

[illegible] **Rahling**, Chicago; Northwestern University [illegible] ol, 1906; aged 36; died at his home, September [illegible] onchopneumonia.

[illegible] **Thomas Lindsay**, Springfield, Ill.; Miami Medical [illegible] e, Cincinnati, 1869; aged 75; died in the Springfield [illegible] ital, September 20.

William F. Elmendorf, Buffalo; University of Buffalo, 1890; [illegible] ed 64; died at his home, September 28, from spinal meningitis.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

PHILLIPS' PHOSPHO-MURIATE OF QUINONE COMP.

Report of the Council on Pharmacy and Chemistry

The following report on Phillips' Phospho-Muriate of Quinine Comp. has been adopted by the Council and authorized for publication.
W. A. PUCKNER, Secretary.

Phillips' Phospho-Muriate of Quinine Comp.[1] is sold by the Charles H. Phillips Chemical Co., New York. According to the published formula, each fluidrachm contains:

Phosphoric Acid	2 minims
Potassium Phosphate Magnesium Phosphate Calcium Phosphate Ferric Phosphate	2¼ grains
Quinin Muriate (equal to nearly ½ gr. Bi-Sulph.)	¼ grain
Strychnin	1/120 grain
Flavoring, Glycerin and Syrup, *q. s.*	

Some typical claims made for the preparation are:

> "With marked beneficial action upon the nervous system. To be relied on where a deficiency of the phosphates is evident."
>
> ". . . brace those tired nerves and aid that worn stomach with Phillips' Phospho-Muriate of Quinine."
>
> "The maintenance of a satisfactory blood pressure level free from intervals of depression may be accomplished by the use of Phillips' Phospho-Muriate of Quinine Compound in appropriate doses."
>
> "The quantities of quinin and strychnin in this preparation are so well balanced that they relieve the depression and fatigue from mental or physical exertion, without the necessity of recourse to alcoholic stimulation."
>
> "The other ingredients of Phillips' Phospho-Muriate of Quinine—phosphoric acid, and the phosphates of potash, magnesia, lime, and iron—are the most rational as well as convenient means of administering these tissue remedies, and of introducing phosphorus—the vitalizing constituent of the nervous system—into the organism."

The action of such a mixture as a whole is practically that of the sum of the actions of its constituents. The therapeutic action of strychnin and quinin are described in every textbook of therapeutics, but it is necessary to distinguish carefully between the various conditions in which these alkaloids have been used without discrimination, and those conditions in which they have been proved to be of value. While both have been widely used in a great variety of conditions, neither is of proved value in more than a distinctly limited range of diseases. The manufacturers of Phillips' Phospho-Muriate of Quinine Comp. seem to appeal to the less discriminating who use these alkaloids without any definite conception of exactly what they seek to accomplish with them. Quinin, although used by the uncritical in a host of diseases, has a definite field of usefulness in the treatment of malaria, both prophylactic and curative, but the required dose in the treatment of malaria is many times larger than that recommended in the Phillips' preparation. The claim that the "strychnin and quinin in this preparation are so well balanced that they produce a mild, buoyant effect, so advantageous, instead of alcoholic stimulation, to relieve depression and fatigue from mental or physical exertion" is nonsensical, if, indeed, it is not mendacious balderdash.

---

[1] The evolution of "Phillips' Phospho-Muriate of Quinine Comp." from "Phillips' Wheat Phosphates" may be interesting. Every one knows that therapeutics tends to fashions, and "Phillips' Wheat Phosphates" appears to have had its inception as the result of the observation that super-refined white flour contains less phosphates than the corresponding amount of wheat. It was assumed that such flour must be deficient in an essential constituent, and the Wheat Phosphates preparation was apparently designed to fill the want. It was exploited for the relief of numerous conditions that were supposed, without satisfactory evidence, to result from this deficiency. When iron, quinin and strychnin mixtures became the vogue a quarter of a century ago, it was only natural to ride on the wave of popularity and the already widely advertised "Wheat Phosphates" was further enhanced—commercially—by the addition of the iron, quinin and strychnin, the amount of alkaloid added being practically negligible. Those who are not familiar with the various phases of the phosphorus, phosphoric acid, lactophosphate, lecithin, nuclein and glycerophosphate propaganda are referred to a report of the Council on Pharmacy and Chemistry in THE JOURNAL A. M. A., Sept. 30, 1916, p. 1033.

Calcium and potassium have important functions in the body, but any deficiency that may arise is usually attributable to an inability of the body to utilize that which is supplied, for there is seldom any deficiency of these salts in the food, and when they are needed they are best supplied as simple solutions of the salts in appropriate doses without all of the other constituents of Phillips' Phospho-Muriate of Quinine Comp.

Phosphoric acid exerts practically the same actions as other mineral acids, hydrochloric being usually preferred for internal administration in certain forms of indigestion, aside from which they are seldom used as such.

In the more recent literature for Phillips' Phospho-Muriate of Quinine Comp., we find the attempt to utilize the well known craze about phosphorus, which has been through so many phases, every one of which has had its day and has been discarded.

The phosphoric acid and phosphates present in Phillips' Phospho-Muriate of Quinine are of no more value in nervous diseases than is simple sodium phosphate which does not require the addition of a host of other ingredients for its action. As a matter of fact, the phosphates of calcium and potassium present in a dose of Phillips' Phospho-Muriate of Quinine are probably devoid of appreciable effect in practically all conditions.

To pretend that one who suffers from physical and nervous exhaustion can be materially benefited by this mixture is sheer nonsense and is unworthy of a moment's consideration by a clinician who is called on to treat such patients.

Iron is useful in anemia, as every one knows. Iron has practically no other field of usefulness in therapeutics. When it is indicated it should be administered in a simple form, such as the pill of ferrous carbonate, for example, and not in a "shotgun" mixture that is quite as likely to do harm as good.

The claim that a satisfactory level of blood pressure can be maintained by Phillips' Phospho-Muriate of Quinine is mentioned only to condemn as the limit of impudent therapeutic claims. It is an insult to the intelligence of any practitioner to pretend that any known agent or combination of remedial agents can maintain a uniform blood pressure in any one of innumerable conditions.

In short, Phillips' Phospho-Muriate of Quinine Comp. is a complex and irrational mixture exploited by means of unwarranted claims. It is a survival of the old days of therapeutic chaos when impossible and fantastic chemical formulas were gravely published and as solemnly accepted without question, and also without the slightest understanding on the part of many; when the most eminent of practitioners did not hesitate to give glowing testimonials for lithia waters that contained no more lithium than ordinary river water; when no therapeutic claim was too preposterous to receive acceptance, no theory too nonsensical to justify the use of all manner of claptrap mixtures for all manner of conditions.

Contrasting Casualty Lists.—The *Health Bulletin*, State Board of Health of North Carolina, has adopted the unique experiment of printing in its *Health Bulletin* the names of the boys from that state who have been killed or wounded in France and comparing it with lists of those killed at home by typhoid fever, those severely injured in the performance of duty, and those seriously injured through carelessness or ignorance in their home state. It is shown that in France, for this year up to August 1, eighty-six "Tar Heels" have given up their lives or have been wounded in battle. During the same period 1,379 citizens of the state have needlessly given their lives or suffered weeks of illness because of typhoid fever. The eighty-six who died or were wounded in France were in the performance of duty. The 1,379 who died or suffered in North Carolina from typhoid fever died or suffered from an absolutely preventable disease.

Correspondence

ABORTION AS A SEQUELA OF INFLUENZA

To the Editor:—In the epidemic of influenza now prevalent I have noticed that pregnant women are especially liable to die. They usually abort or contract the very pronounced type of pneumonia, with cyanosis, the lungs full of coarse, mucous râles, and death in from two to three days.

In Stroudsburg, where I assisted Dr. Angle, nearly every pregnant woman I saw died. Dr. Durham, who has just returned from a mining camp near Punxsutawney, reports a similar condition. I do not recall anything like this in previous epidemics and have seen no mention of the fact in this one.

Bacillus abortus of Bang is so closely allied to the influenza group that the question of their being identical is raised by these observations.

In Ziemssen's Encyclopedia, 1875 edition, in an article by Zuelzer, I find: "Pregnant women frequently suffer abortion. . . . This effect of influenza repeatedly verified in many epidemics . . . analogous phenomenon in other infectious diseases."

M. W. Ball, M.D., Warren, Pa.

CONTRIBUTIONS FOR BELGIAN AND FRENCH PHYSICIANS

To the Editor:—I beg to acknowledge through your columns the following contributions in cash to aid the civilian physicians of Belgium and France when they again return to their looted offices. The prospect now is that they will soon be able to do so. Meantime the money that I have forwarded to Professor Depage in LaPanne and the Comité d'appui des réfugiés de professions libérales through the Belgian and French Relief Associations of this city are accumulating in bank ready to be used whenever it is possible to do so.

Including the prior contributions, the sum total that I have been able to forward is $2,624.88, and the estimated value of the instruments that have been forwarded amounts to $4,360.

I wish particularly to acknowledge the very generous contributions of Dr. Gifford and his partners in Omaha. They have contributed $1,000 of the entire amount. Dr. C. T. Faries of Narberth, Pa., also most generously gave $10 a month for eight months, when he entered the service.

I trust that the members of the profession will be willing now to give more largely than before because the need is urgent. The villainous destruction which the Huns are visiting on even every little village has wiped out practically everything that our civilian confrères ever had. They will resume their work with nothing but willing hands and warm hearts. It is up to us to help them out of their troubles.

SUBSCRIPTIONS IN CASH

Dr. William G. Rowe, Blue Springs, Mo.	$ 5.00
Dr. Clarence T. Faries Narberth, Pa. (fifth, sixth, seventh and eighth contributions)	40.00
Dr. H. Gifford and his partners, Drs. James M. Patton, W. F. Callfas and John B. Potts, Omaha	500.00
Dr. Anna Odell, Detroit	10.00
Dr. Clyde L. Cummer, Cleveland	5.00
Dr. C. W. More, Eveleth, Minn (through Dr. John M. Robinson, Duluth)	25.00
	$585.00
Additional interest	6.54
	$591.54

DONORS OF INSTRUMENTS

Dr. Alexis Dupont Smith, Philadelphia; Miss E. K. Bray, New York; sundry physicians through Dr. J. M. Robinson, Duluth, Minn.; Dr. Walter J. Freeman, Philadelphia; Widow of Dr. A. T. Clark, Shickshinny, Pa.; Dr. F. S. Spearman, Whiting, Iowa; Dr. Charles M. Montgomery, Philadelphia; Dr. W. Estell Lee, Philadelphia; Dr. C. L. Cummer, Cleveland; Dr. L. B. Pilsbury, Lincoln, Neb.

Messrs. Harvey R. Pierce & Co. have very kindly put these instruments in order and packed them for transmission to Europe.

W. W. Keen, M.D., Philadelphia.

Major, M. C., U. S. Army.

ATTITUDE OF CHRISTIAN SCIENTISTS IN THE PRESENT EPIDEMIC OF INFLUENZA

To the Editor:—Your optimistic current comment (The Journal, Oct. 12, 1918, p. 1223) concerning the change in attitude of the public toward public health methods would be highly reassuring if it were true in the measure that the comment indicates. You say, "When health authorities place a ban on public gatherings, when they insist that the windows of public conveyances be kept open, when they insist on absolute quarantine in order to stop the spread of the disease, the public is ready to obey, and does obey to the *fullest* measure" (italics mine). Further, "Another feature is the confidence of the public in public health authorities, apparently the result of the intense education of the public in prophylaxis of disease which has been going on during the past decade."

I beg to call your attention to a special telegram to the Philadelphia *Public Ledger*, dated Boston, October 7, which reads thus:

> In connection with the influenza epidemic, the directors of the "Mother" Christian Science Church here announce that "the mind is a source of contagion" and that "ailments can contaminate only as diseased images are held before the thought and paraded before excited imagination preliminary to having them expressed on the body through fear and apprehension."
>
> They declare that "disease is being industrially promoted through the common avenue of mesferic [sic] wear," and quote Mrs. Eddy as follows:
>
> "At a time of contagious disease, Christian Scientists endeavor to rise into consciousness to the true sense of omnipotence of life, truth, and love, and this great fact, as Christian Science realized, will stop a contagion."
>
> *The church held its regular services Sunday, explaining that good rather than harm was effected. The health officials had asked churches to close during the influenza epidemic* [italics mine].

This sort of stuff is doubtless doped out in every Eddyite congregation in the United States, and even the least observing and he of dullest comprehension must have discovered that the following of this cult is large. I have been told that Chicago is a veritable hotbed of Eddyism.

Would it not be wise to bend some editorial energies, if any are available, to the scotching or killing of this skunk in lieu of complacently recording dubious impressions? Here at home the Eddyites have not been able to get by with their "activities" unchallenged.

C. B. Burr, M.D., Flint, Mich.

ILL ADVISED REFERENCES TO TREATMENT IN ARTICLES ON PUBLIC HEALTH PROBLEMS

To the Editor:—The attached clipping is a part of a "syndicated article" that has appeared in a number of newspapers. It strikes me that this line of so-called information is wrong. In writing on any public health problem, the writer should avoid reference to treatment. The treatment of any particular disease should be decided by the physician in charge after he has examined the patient. It is not right to state baldly that "drugs are virtually impotent." The patient calls the physician for his own relief and benefit, and if he believes all of this article he will probably send to the drug store and buy his own aspirin. And, by the way, is this writer in the pay of the Bayer people and helping them to put across their advertising campaign? Self medication is now one of the great banes of the American people, and such articles, either in the public press or in board of health publications, are the greatest incentive to such "doping." A carefully considered statement on any medical subject is often misquoted both in the medical and the lay press, as instance the comment aroused by Osler's age limit and Bevan's talk on pneumonia some years ago, both of which are still wildly and widely misquoted in both lay and medical publications. No two cases of any acute infection can be treated in exactly the same manner; the age and surroundings of the patient, the condition of the heart, kidneys, lungs and other organs must be taken into consideration, and the very necessary steps taken to avoid dangerous and possibly fatal complications and sequelae. Aspirin may be dangerous or even fatal in some cases, as may other salicylates. Another bad effect of self medication is that a case improperly diagnosed as epidemic influenza will not be reported, and may be the starting point of a dangerous epidemic. In fact, a case so diagnosed may be almost any one of the infectious diseases. I have seen severe cases of smallpox diagnosed as grip in the early stages, and an epidemic start therefrom.

The authorized public health publications of many states and occasionally of the Public Health Service have been guilty of the actions of which I complain. I think these mistakes are largely due to carelessness on the part of these writers, and calling their attention to them will have a good effect. I was one time the state health officer of one of the Southern states, and know how easy it is to overlook important matters and to make mistakes of judgment.

F. B. Young, M.D., Gering, Neb.

[Comment.—The clipping to which our correspondent refers reads:

> It should be remembered, too, in treating patients who have acquired "Spanish influenza," care and sanitation are the all-important points. Drugs are virtually impotent, although aspirin may be administered to relieve headaches and body pains. With proper attention the disease will run its course in three days and the patient fully recover in less than two weeks. Death seldom ensues, except through neglect.

No doubt it would be in the interest of public health and the public pocketbook were medicines taken only on the advice of physicians. The objections to the lay advertising of aspirin were thus stated by the Council on Pharmacy and Chemistry:

> The public does not know, as physicians do, that headaches are merely symptoms of other, sometimes very serious conditions, and that they are often the signal for the need of a thorough physical examination and diagnosis. It is true that they are often also the symptoms of very minor derangements, which will right themselves spontaneously; and that, in such cases, drugs like aspirin may give relief and may do no harm. The patient, however, is not educated to distinguish one class from the other, and therefore anything that tends to promote the indiscriminate use of such remedies as aspirin itself is not always harmless. Alarming idiosyncrasies are sufficiently common that the use of the first doses, at least, should require medical supervision.—Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PURCHASE OF MEDICAL OFFICERS' EQUIPMENT THROUGH QUARTERMASTER'S DEPOT

To the Editor:—In The Journal, October 5, you say that officers' uniforms are available through the quartermaster's department, one depot being located in Chicago. Will you please give me the address?

H. T. K., Joliet, Ill.

To the Editor:—I have been examined for a commission in the Army and expect to be commissioned soon. Will you please tell me if I can buy my uniform and equipment at cost from a quartermaster as provided in the last clause of the "Man Power Bill"? If so, can I get them from the quartermaster of any camp?

L. W. C., Franklin, N. Y.

Answer.—In The Journal, October 5, page 1142, appears an item relative to the furnishing of uniforms through various quartermasters' depots. The seven depots mentioned are at New York, Washington, Atlanta, Ga., Fort Sam Houston, Texas, San Francisco, Chicago and St. Louis. Officers desiring to purchase uniforms may communicate with the nearest quartermaster's depot. We are informed by the officer in charge of the quartermaster's depot at Chicago that they are authorized to sell to newly appointed officers, on presentation of the telegram notifying them of their appointment or commission, any articles on the list of goods furnished, at the prices and in the maximum quantities shown. The Chicago sales room is located in Bungalow A, Thirty-Ninth Street and Winchester Avenue. Newly appointed officers residing outside of Chicago may communicate by mail with this department, or with the nearest quartermaster's depot, and the proper forms and information relative to purchase of equipment will be sent to them. The list of equipment and prices is not available for general publication, but will be furnished by the quartermaster to any officer on application. It includes practically everything that the officer will require.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Little Rock, Nov. 12-13. Sec., Regular Bd., Dr. T. J. Stout, Brinkley, Ark.; Sec., Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith.

CALIFORNIA: Sacramento, Oct. 21-24. Sec., Dr. C. B. Pinkham, State Capitol, Sacramento.

CONNECTICUT: New Haven, Nov. 12-13. Sec., Regular Bd., Dr. C. A. Tuttle, 196 York St., New Haven; Sec., Eclectic Bd., Dr. James E. Hair, 730 State St., Bridgeport; Sec., Homeopathic Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

MAINE: Portland, Nov. 12-13. Sec., Dr. Frank W. Searle, 776 Congress St., Portland, Me.

MASSACHUSETTS: Boston, Nov. 12-14. Sec., Dr. Walter P. Bowers, No. 1 Beacon St., Boston, Mass.

NEVADA: Carson City, Nov. 4. Sec., Dr. S. L. Lee, Carson City.

TEXAS: Dallas, Nov. 19-21. Sec., Dr. M. F. Bettencourt, Mart.

WEST VIRGINIA: Charleston, Nov. 19-21. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Minnesota June Examination

Dr. T. S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, practical and written examination held at Minneapolis, June 4-7, 1918. The examination covered 15 subjects and included 80 written questions. An average of 75 per cent. was required to pass. Forty-one candidates were examined, all of whom passed. Six candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Northwestern University	(1918)	92
University of Illinois	(1918)	89
Boston University	(1915)	85
University of Minnesota		(*) 86, 86, 86, 87, 87, 88, 88, 88, 88, 89, 95; (1918)† 77, 80, 83, 86, 87, 87, 88, 89, 89, 89, 89, 90, 90, 91, 91, 91, 92, 92, 92, 92, 92, 93, 93; (1918) 91.

Marquette University	(1915)	Wisconsin
Milwaukee Medical College	(1911)	Wisconsin

*Degrees held pending removal of conditions.

†Received M.B. degree on completion of four years' work. M.D. degree granted on completion of internship.

Rhode Island July Examination

Dr. B. U. Richards, secretary of the Rhode Island State Board of Health, reports the practical and written examination held at Providence, July 11-12, 1918. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Four candidates were examined, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Maryland Medical College	(1913)	83
Tufts College Medical School	(1918)	84.7, 89.4, 91.2.

Utah July Examination

Dr. G. F. Harding, corresponding secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, July 2-3, 1918. The examination covered 19 subjects and included 100 questions. An average of 75 per cent. was required to pass. Three candidates were examined, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Rush Medical College	(1917)	84.8
Johns Hopkins University	(1918)	79
University of Maryland	(1917)	79.4

Dr. Harding also reports that 3 candidates, including 1 osteopath, were licensed through reciprocity, July 5, 1918. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Denver College of Medicine	(1883)	Colorado
Columbia University	(1897)	Colorado

Book Notices

THE DISPENSATORY OF THE UNITED STATES OF AMERICA. Thoroughly revised, largely rewritten and based on the ninth revision of the United States Pharmacopoeia and the British Pharmacopoeia, 1914. By Joseph P. Remington, Ph.M., F.C.S., chairman of the Committee of Revision of the Pharmacopoeia of the United States of America; Horatio C. Wood, Jr., M.D., Professor of Pharmacology and Therapeutics in the University of Pennsylvania; Samuel P. Sadtler, Ph.D., LL.D.; Charles H. LaWall, Ph.M., Associate Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy; Henry Kraemer, Ph.G., Ph.D., Professor of Botany and Pharmacognosy in the University of Michigan; and John F. Anderson, M.D., Director of the Research and Biological Laboratories of E. R. Squibb & Sons. Twentieth edition. Buckram. Price, $12. Pp. 2150. Philadelphia: J. B. Lippincott Company, 1918.

This book and the authors are so well known that words of introduction are unnecessary. We find the statement on the title page to be strictly true; the volume has been thoroubly revised and largely rewritten. The scope of the works of reference consulted in its compilation seems to have been broadened. Aside from the United States and British Pharmacopeias, the National Formulary and New and Nonofficial Remedies, more than 200 titles appear in the list of journals, etc., used for reference. It is pleasing to note that the statements quoted from these sources are treated in a critical manner; in fact, the policy of constructive criticism seems to have been adopted, a thing not very pronounced in previous editions. A valuable feature is the thorough manner in which the Federal Food and Drugs Act and the Harrison Narcotic Act are elucidated. The general arrangement of the text is the same as in previous editions. Part I, Pages 1 to 1222, contains the discussion of the articles described in the United States and British Pharmacopeias. As an aid to reference, a uniform style of treatment has been adopted; and, as previously, various features, such as properties, uses, preparation and commercial history, are set off by boldface type. Incompatibilities receive special attention and always appear at the end of the paragraph on uses. In Part II are considered those articles that are described in the National Formulary and New and Nonofficial Remedies, and those other things that are thought to be of sufficient interest to warrant mention. Part III, Section I, contains with a few exceptions a reprint of Part II of U. S. P. IX, Appendixes I to XIII inclusive of the British Pharmacopeia, and numerous tables of specific gravity and the like. Part III, Section II, contains Part I of the National Formulary in abstract. With all, the United States Dispensatory, Twentieth Edition, is a valuable book of reference, and this encyclopedia of drugs should be in the possession of every physician who aims to have an efficient reference library.

THE INDIAN OPERATION OF COUCHING FOR CATARACT INCORPORATING THE HUNTERIAN LECTURES DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS OF ENGLAND. By Robert Henry Elliot, M.D., B.S., Sc.D. Cloth. Price, $3.50. Pp. 94, with 45 illustrations. New York: Paul B. Hoeber, 1918.

This booklet represents the Hunterian lectures delivered before the Royal College of Surgeons of England in 1917. The work of Colonel Elliot is perhaps the most important done on this subject. He presents the history of couching beginning with the operation first described by Celsus, following with the technical methods and statistical material, and discusses the pathologic anatomy of couched eyes based on a collection of fifty-four eyeballs which he himself presented to the Museum of the Royal College. This is believed to be the most valuable collection in the world. The final chapters concern the diagnosis and clinical care of these cases.

THE ESSENTIALS OF MATERIA MEDICA AND THERAPEUTICS FOR NURSES. By John Foote, M.D., Assistant Professor of Therapeutics and Materia Medica, Georgetown University School of Medicine. Third edition. Cloth. Price, $1.75. Pp. 310. Philadelphia: J. B. Lippincott Company, 1918.

This edition is based on the new pharmacopeia, New and Nonofficial Remedies, and on Wood's "Pharmacology and Therapeutics." The book is practical; much of it is in outline form. The last hundred pages consist of ready reference tables, lists of drugs, etc., which should be quite helpful.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Thirty-First Annual Meeting, held at Detroit, Sept. 16-18, 1918

The President, Dr. Albert Goldspohn, Chicago, in the Chair

Stab Wound Drainage in Pelvic Infections

Dr. H. Wellington Yates, Detroit: It should be our constant endeavor to close without drainage, so far as safety will permit. Drainage materials should be removed earlier than is done in the general practice now obtaining. The great majority of all infected areas in the pelvis are suitable for culdesac or stab wound drainage. The abdominal incision should be left free to close by primary union. Stab wounds are securely and quickly united after the drainage is withdrawn, with no fear of subsequent hernia. The musculature of the areas usually chosen for stab wound drainage is our greatest asset to a speedy closure of the drainage opening.

DISCUSSION

Dr. Gordon K. Dickinson, Jersey City, N. J.: Drainage is a misnomer. Gauze does not drain. It is a local irritant and because of that property it walls off the local processes to a certain extent and makes things fairly safe. About ten years ago I made a study as to the value of the omentum in abdominal drainage, and I came to the conclusion then, and I feel the same now, that the omentum, properly applied, will drain more in ten minutes than any gauze will take out in a day.

Dr. J. Henry Carstens, Detroit: I have not drained for I do not know how long. I clean out the abdomen thoroughly without washing it. I mop it out and then close the incision without drainage.

Dr. John W. Keefe, Providence, R. I.: Hard rubber drainage tubes in the abdomen have been largely discarded. Most surgeons feel that a hard rubber drainage tube should not be put next to the intestine. There is no question that an incision into Douglas' pouch for drainage is a desirable thing in a few cases. Looking back over the literature of gynecology one can see how many patients have died from the placing of drainage tubes in the pelvis and the withdrawal by nurses of the serum that formed. As soon as surgeons began to close the abdomen and not interfere with nature, these patients recovered.

Dr. Charles L. Bonifield, Cincinnati: Dr. Keefe said that when surgeons began to keep drainage tubes out of the abdomen we got better results. While that is partly true, it is not the whole truth. One of the reasons we get better results now is that abdominal surgeons are improving their technic, and drainage becomes less necessary.

Dr. Hugo O. Pantzer, Indianapolis: I concur in what Dr. Bonifield says, but there are cases in which we cannot get along without some form of drainage, cases with an accumulation of pus indicating that the peritoneum is unable to cope with it at that time, and hence some form of drainage is necessary.

Pathologic Conditions of the Pelvic Viscera, the Result of Induced Abortions Causing Sterilization

Dr. Francis Reder, St. Louis: All abortions, whether induced or not, pave the way, sooner or later, for sterilization of the woman. An instrumentally induced abortion is more prone to cause sterilization than an abortion induced by therapeutic measures. The resultant pathologic changes in the pelvic organs, following an abortion, can be judged only vaguely. An abdominal section on a healthy woman who, in previous years, has had her pregnancies interrupted, causing sterilization, and who now desires to have a child, is a justifiable procedure after all therapeutic and minor gynecologic measures have proved of no avail. In the application of these measures, an approximate time limit of no less than two years, and of no more than three years, can be assumed. The correction of the pathologic conditions present may or may not enable the woman to become pregnant. Nothing definite can be formulated from a surgical measure undertaken to remove a barrier to pregnancy.

Cesarean Section Under Local Anesthesia

Dr. William Mortimer Brown, Rochester, N. Y.: The chief conditions for which this form of anesthesia may be chosen are myocarditis with relaxed muscle, toxemia with urinary insufficiency, pulmonary tuberculosis, and other conditions that may contraindicate a general anesthetic.

Cesarean Section

Dr. Abraham J. Rongy, New York: My experience with this operation consists of 109 cases, eight of which terminated fatally. During a period of twelve years I saw approximately 1,500 women in labor, all of them presenting some form of dystocia. Out of this great number I resorted to cesarean section eighty-two times. Cesarean section has no place in eclampsia when nature has already commenced to do its work, that is, when labor has already set in. In such cases large doses of morphin are the best form of treatment. Cesarean section has no place in the preeclamptic stage. In such cases one always has time to induce labor, and the results are usually very satisfactory. Only he who is well trained in obstetrics has a right to decide on this operation. A general surgeon has not the necessary knowledge to be competent to pass judgment on such an important question — important not only to the woman and to her future pregnancies, but also to the nation. If cesarean section is performed indiscriminately, there is bound to be a decrease in the birth rate, for the average woman will not submit too many times to this operation. For this and many other reasons, cesarean section should be left entirely to the well trained obstetrician.

Treatment of Pregnancy Toxemia

Dr. George Clark Mosher, Kansas City, Mo.: The technic that involves least shock consists of: (1) Preliminary gradual dilatation by Hegar's dilators up to No. 20; (2) Voorhees bag No. 4, if at term, introduced by Reed's method—cigaret roll held by Pean's forceps; lavage with sodium bicarbonate, 2 per cent., after uterus is emptied. Cases of the fulminating type, long hard cervix (in which no vaginal examination has been done), are best treated by classical cesarean section. When after contamination by frequent digital examination, infection is almost surely to be expected, a Porro or other hysterectomy should be done in the interest of the mother. I have had 95 per cent. recoveries of mothers, and 85 per cent. of the children at term. From my own experience, and that of other observers, including a report by Dr. Ben Meyers of Alaska, who finds that in the last year, an unusually cold wet season, 12 per cent. of his cases suffered from toxemia—the conclusion is drawn that the weather does at least aggravate the tendency to this condition. As there is a close relation between the toxemia and the nervous system, is it not also fair to ascribe to the war an incidental effect as a causative factor?

Observations on Interned Venereal Patients

Dr. James E. Davis, Detroit: All cases of the series were examined serologically by the state board. Bacteriologic examinations of the smears taken from the urethral meatus, Bartholin's duct meatus, cervix uteri, and vagina were repeatedly made. Methylene blue and gram strains were employed. Patients were pronounced cured after the clinical disappearance of all lesions, and after obtaining negative Wassermann reactions before and after provocative arsphenamin injections and after five consecutive smears, preceding which provocative doses of gonococcal vaccine had been administered. The average age of the patients was 17 years, and fourteen were married. The average length of time patients were confined in the hospital was thirteen weeks. The average cost to the state per patient was $195. There were ninety cases of gonorrhea and syphilis, forty-six of syphilis, seventy-two of gonorrhea with positive laboratory findings, and ten of gonorrhea, clinically positive, with laboratory findings negative.

Recognition and Management of Labor Injuries

Dr. Arthur J. Skeel, Cleveland: I wish to emphasize four points: 1. Limiting or entirely avoiding vaginal examinations during labor is a routine preliminary part of the technic of primary repair of labor injuries. 2. Immediate inspection of the cervix, with primary repair of its injuries, reduces the risk of subinvolution and of uterine displacement. 3. The routine use of buried sutures in the perineum for the repair of second degree lacerations permits accurate coaptation and restoration of the parts. 4. Perineal lacerations are more surely repaired than is subpubic damage. Therefore, slow delivery and skill in directing the small diameters of the head through the vulvar ring should be sought. Forcing the head against the pubic arch produces more damage than it prevents.

Vertigo of Menopause

Dr. K. I. Sanes, Pittsburgh: In most of our patients the vertigo was of the objective type, that is, they experienced a sense of rotation around them of the visible or palpable environments. In some of them the vertigo was of a subjective type, a sensation of motion of the body itself. A few of our patients described the vertigo as a sort of swimming movement, a feeling of being intoxicated, an extremely embarrassing condition (the pseudonarcotism of Tilt). Vertigo was seldom the only prominent menopause symptom; it was almost always accompanied by hot and cold flashes, cold perspiration, palpitation, blurred vision, flickering before the eyes, headache, nausea, tinnitus, etc. The relation of vertigo to climacteric functional hypertension is of interest, and it is claimed by some that it is responsible for the menopause vertigo. Excluding as far as possible the cases of organic hypertension (cardiovascular and renal), we found 102 patients with vertigo that had their blood pressure specified on their records, and of these only 45 or 46 per cent. had their blood pressure above 150, and only 20 or 30 per cent. above 160.

In most of our cases, the vertigo was only slight, just a mild dizziness; in others it was so severe that they feared walking by themselves on streets on account of the frequent falls and even loss of consciousness during the attacks of vertigo. If the case can definitely be diagnosed as that of climacteric vertigo, the treatment to be outlined must be that of menopause in general.

The results obtained from the use of ovarian substance, while sometimes strikingly good, are so frequently negative as to raise the question whether it has within it the same finished product or products that the internal secretion consists of; and if it has, whether it is competent to take care of the functional changes of the correlated endocrine glands brought about by the functional changes of the ovarian secretion.

The Heart of a Pregnant Woman

Dr. Louis Burckhardt, Indianapolis: An early diagnosis is the chief factor for successful therapeutics. The menstrual disturbances, the aversion to physical exercise and the vasomotor symptoms will help greatly to single out suspicious cases. To depend on marked objective changes in the heart and the general system will lead to a loss of valuable time. If a heart affection has progressed to a point where drastic measures are unavoidable, irreparable damage has been inflicted on mother and fetus. Under drastic measures I include prolonged and absolute rest in bed, the use of opiates and large doses of digitalis; all these must interfere with a normal metabolism, so essential in this condition.

The first prophylactic steps ought to prevent impregnation, the prohibiting of marriage or the avoiding of conception. If, however, conception has taken place, the pregnancy, in all but the severest cases, must be carried to term. The interruption of pregnancy offers as many chances of a cardiac breakdown as a normal well conducted delivery—excepting an abortion induced before the formation of the placenta has begun. If a patient with a well compensated heart lesion presents herself for prenatal care, we must impress on her mind the necessity of preservation of energy. Saving alone does not suffice, but working up of new vital forces is needed. Not rest alone, but rest and exercise. We demand regular exercises and careful attention to elimination in every normal case; we must control both most minutely in heart cases. The blood pressure readings will assist greatly in controlling the patient's work. Between the thirty-fourth and the thirty-fifth week of pregnancy, daily observations will be necessary in order to determine the proper time of interference. During this period such patients are best strictly confined to bed. As soon as settling has occurred, a considerable amelioration of symptoms is frequently observed and the patient may be given more liberty of action.

(*To be continued*)

COLORADO STATE MEDICAL SOCIETY

Forty-Eighth Annual Meeting, held at Estes Park, Sept. 9-11, 1918

(*Concluded from page 1246*)

Spastic Irritability of the Intestinal Tract

Dr. Julius L. Mortimer, Denver: A spastic state is due to exaggerated physiologic tonic contractions either of circumscribed areas or of entire intestinal segments, or to cramplike constrictions of the peristaltic waves. The intensity and duration of this condition varies according to the disposition of the patient and the nature of the prevailing cause. Prevailing causes are to be sought in the abnormal irritation from the intestinal contents, or in mechanical or chemical reflexes by the formation of large amounts of liquid or gaseous decomposition products. An increase of intestinal contents alone will often produce abnormally increased motility. This may be a consequence of hurried eating or poor mastication. Large undigested food substances as well as foreign bodies will generally pass through the small intestine rapidly without any manifestations. Disturbances will occur usually in the large intestine, where local spasms will be intensified by the occlusion of the foreign body.

Inflammations and new growths of the intestinal wall will result in an increased irritability of the automatic centers of motility. A frequent cause of intestinal spasm as a result of toxic action is found in lead poisoning and nicotin poisoning. Proctospasm may be caused by irritation through the sacral autonomic system, the pelvic nerve, as in tabetic crises, hysteria and neurasthenia.

DISCUSSION

Dr. Leonard Freeman, Denver: Perhaps the most startling and most characteristic form of spasmodic obstruction is that which takes place in the small intestine, usually in the lower portion of the ileum, where a section of bowel not more than from 3 to 6 inches in length will contract to the limit so that it is hard and white and bloodless, not bigger than a lead pencil or fountain pen, and so firm that one can pick it up by one end during a surgical operation and it will stand out straight without bending. This obstruction may take place in many portions of the intestinal canal, but it is usual to find it in one particular place. The contraction is so cut off from the rest of the bowel that the walls of the adjacent intestine are perpendicular. The causes of this obstruction are extremely obscure. The only thing we can say is that it is due to a reflex irritation arising generally in the intestinal canal itself, but possibly arising in other portions of the abdominal cavity like a twisted ovarian pedicle or strangulated hernia, or a twisted testicle or vein. It may follow any kind of surgical operation.

Dr. J. E. Matlack, Longmont: Spasm of the gastro-intestinal tract is both a great help and a great hindrance to diagnosis by means of the roentgen ray. It is a help in that many of the roentgen signs of disease of the stomach, for instance, are due to spasm, to deformity of the duodenum in duodenal ulcer as the result of spasm of that portion of the intestine, and in that way the diagnosis can be made definitely. A valuable method of differentiation between spastic and organic conditions of the stomach is repeated roentgen examinations and the administration of the tincture of belladonna.

Fractures of the Tibia

Dr. William Senger, Pueblo: During the past three years we have treated ninety-two cases of tibial fractures; twenty-five were compound and forty-four comminuted; eight involved the knee joint and twenty-eight the ankle. Amputation because of thrombosis was necessary in one case. As soon as possible the fractured leg is roentgenographed. The preliminary treatment of simple fracture consists of placing the limb in a blanket splint resting on a pillow and further protected by sand bags. Ice caps are applied and nothing further done until the swelling has nearly disappeared. The fracture is then reduced under the fluoroscope. When thus treated, we have never had a simple tibial fracture that has not given good results.

Comminuted fractures can usually be treated as simple fractures; but when the fracture involves the ankle joint or the knee, it may be impossible to reduce and fix properly, except by open operation. Likewise, it is the rule that an open operation is almost imperative in a comminuted spiral fracture with the fibula splintered at a higher level. We do not use the intramedullary autogenous graft. We feel that destruction of the bone marrow is a mistake. In open operations we have completely abandoned the use of all metallic substances for fixation. The autogenous graft answers every purpose and avoids the possibility of future irritation. In the treatment of compound fractures we follow the Carrel-Dakin method. It has proved most satisfactory. In a compound fracture the soft parts should never be sutured in the first aid dressing. It is far better to pour half strength tincture of iodin into the wound and about the surrounding parts. After this has dried, a loose, sterile dressing should be applied, the limb placed in a blanket splint, immobilized, and, if possible, the patient sent to a hospital for further treatment.

The von Pirquet Test in Four Hundred and Sixty-Four Children

Dr. Emanuel Friedman, Denver: These patients ranged in age from a few months to 18 years. The acutely ill were excluded. The majority had abundant opportunity for infection. Most of the children were of tuberculous parents, many of whom had been inmates of sanatoriums in which they have had thoroughly inculcated rules of prophylaxis, which were scrupulously observed in many of the homes. The material conformed in kind with that on which most reports bearing on the frequency of childhood tuberculosis are based.

Of the 464 children tested, 39.8 per cent. reacted positively. Under 1 year, almost 12 per cent. reacted positively; from 10 to 14 years, 55 per cent., and from 14 to 18 years, only 51 per cent. The highest number of positive reactions was noted during the 11 to 13 year period, with 66.7 per cent.; and the lowest at the 5 to 6 year period, with only 13 per cent. positives. A comparison of these figures with those obtained at other sources warrants the conclusion that tuberculous infection among children in Colorado, while not as frequent as in Europe, is certainly no less frequently observed than in other American cities, barring New York.

Water Hemlock Poisoning

Dr. Mary R. Stratton, Denver: Eleven boys, between the ages of 8 and 12 years, were seriously poisoned by eating the root of the water hemlock or *Cicuta occidentalis*. Two of the cases were fatal. The boys had eaten the root after 6 o'clock while out on the grounds after their evening meal. They were taken sick in about an hour after eating. Those first taken sick had been in convulsions between thirty and forty minutes when I first saw them—others for a much shorter time. The sickness began with acute cramp or severe pain in the stomach, with an inclination toward a bowel movement, and vomiting. Mostly the vomit was a clear, frothy fluid. Those that vomited the stomach contents were not so sick. They then became dazed and fell wherever they were and went into the most frightful convulsions and unconsciousness. None of them remembered anything about the events of that night when they awoke in the morning. The spasms were of a tonic character, with cyanosis and frothing at the mouth. The pupils were widely dilated, with the eyes open, eyeballs rigid and no corneal reflex. With some, the eyes were rolled up and the head drawn backward when they went into the convulsions, and they became rigid in that position. In the case of others, the eyes were bent downward and the head forward. The jaws became locked, and it was impossible to give them anything by mouth. The legs were somewhat parted and partly flexed. The arms partly flexed and held from the body, the hands clenched and finger nails blue. The muscles of the whole body were rigid and hard. In those who had been in convulsions some time, the pulse was fast, irregular and weak. During the severe convulsions, the breathing was interfered with to such an extent that the face was blue and livid, and one wondered if they might not die from suffocation. The external surface of the body was cold. There was no bowel action or urination during the convulsions. Once in a while the convulsions would relax only to return again.

The treatment consisted of stomach lavage with a weak tannic acid solution, hypodermic stimulation, chloroform inhalations for the convulsions or twitching, and a dose of salts in the morning. Those who vomited and evacuated the stomach thoroughly at the beginning had a good prognosis. The poison is absorbed rather slowly from the stomach, so that if the stomach is evacuated, even some time after the drug has been taken, it will often prevent a fatal termination

Seminal Vesiculitis: Its Treatment

Dr. William M. Spitzer, Denver: Seminal vesiculitis may cause all the symptoms of a cystitis with its resultant miseries. It may result in an abscess with high temperature, prolonged prostration, and eventually death, simulating typhoid. Peritonitis occasionally, but rarely, ensues from a rupture of such an abscess into the peritoneal cavity. Colic, simulating renal colic, may appear, and the presence of pus in the urine at some time complicates the picture still more. Various ejaculatory disturbances, such as premature ejaculation, bloody ejaculation, painful ejaculation, or abscence of ejaculation at the termination of coitus, exists. Dysuria, pollakiuria, inability to urinate and other urinary disturbances may add to this condition. Various reflex pains, such as suprapubic, perineal, rectal, lumbosacral, sciatic, intra-abdominal (simulating appendicitis) and lumbar pains (simulating renal lesions) are common.

With the vesicle as a focus of infection, any condition may arise. Very common are various arthritides (gonorrheal), myocarditis, iritis and even choroiditis; and infections in any of the organs may ensue.

The following symptoms are more or less classic: 1. Pain; an infected seminal vesicle is always painful or tender to the touch. 2. Induration of the walls of the seminal vesicle. 3. The bringing forth of large, ribbon-shaped, vesicular casts on vesicular expression. 4. Sensitiveness or pain in the region of the verumontanum, which is determined by the aid of the olivary bougie.

The treatment should be divided into three parts, namely, the treatment of acute vesiculitis, subacute vesiculitis and chronic vesiculitis. There is a class of cases that demands surgical interference. These are the cases in which the seminal vesicle acts as a focus of infection and serious results threaten to follow, such as gonorrheal arthritis, iritis, serious myocarditis and any other diseased condition threatening the life or life work of the patient. Within the last three years I have opened and drained continuously over a period of two weeks the vesicles in fifteen patients suffering from gonorrheal arthritis. In no case had the arthritis (always polyarticular) existed for less than three months, and in each case everything had been done in the way of local treatment and vaccines that was possible, without any effect on the arthritis. In each case the arthritis was completely stopped within a few days, all joints being restored to normal within two weeks. Metastasis is cured by opening and draining the vesicles.

10. Meningitis in New-Born and in Infancy.—Barron reviews the literature and cites one case. A male infant, 11 days old, was delivered in breech presentation. During the latter months of the last pregnancy the mother experienced pain in the epigastrium which was of the character of real labor pains during the last two weeks before delivery. She noticed that her abdomen was excessively enlarged. The childbirth, she thinks, was about one month premature. There was a condition of hydramnios during the second stage of labor, more than one gallon of amniotic fluid escaped. The delivery of the head was assisted by the insertion of a finger into the mouth of the fetus and then using a moderate amount of traction. The infant was cyanotic at birth, and it required considerable effort to initiate respiration. The infant had a whimpering cry and at no time nursed well. A slight right-sided paralysis made its appearance on the third day. The right hand appeared puffy and edematous. On the tenth, day there was a bilateral swelling of the eyelids. Several slight convulsions were noticed on the morning of the eleventh day. The lips turned cyanotic. The child died on the same day. At the necropsy it was found that the brain was covered with a layer of brownish fibrinopurulent exudate. This is most marked over the left parietal region. Smears from the exudate show disintegrated pus cells and immense numbers of extracellular and intracellular gram-negative, short, plump bacilli. The organism recovered by culture was definitely the *Bacillus coli-communis.*

18. Suspension and Traction Treatment of Fractures in Base Hospital.—The idea of treating fractures by suspension and traction is not a product of the present war, as it was first used over a hundred years ago. The adaptation of this method to fractures of the arm and many improvements on the original method of Hodgen for treating fractures of the leg are the results of the present war. Many of the new ideas in this method have been developed by surgeons of the staff of the American Ambulance Hospital, especially by Major Joseph Blake. The introduction of this method in the present war was for the treatment of badly infected compound fractures. It has proved of inestimable value, from both a subjective and an objective point of view. Subjectively, there is absolute comfort to the patient at all times, as the fragments of bone remain in the same relative position when the patient moves about in bed and when the dressing is done. The pain from congestion of the limb is eliminated owing to the improved circulation. Objectively, the edema of the limp disappears as the limb is higher than the body, and there are no tight bandages about the limb; the wound heals more quickly, due to better circulation. Union of fractures occurs early as a result of immobilizing the fragments, and ankylosis of neighboring joints is avoided by massage and motion during treatment. It requires some training and patience to apply the apparatus properly at the first dressing. It also requires watchfulness on the part of the surgeon to maintain a proper application of the apparatus throughout treatment; but the results more than compensate for the added work.

19. Use of Turn-Buckle for Traction in Treatment of Fractures.—The turn-buckle is a peculiarly unique mechanism where carefully controlled traction and counter-traction has proved necessary under roentgen-ray findings, and Holyoke believes that it will find a very important place in surgery. He describes a case to illustrate the use of the buckle.

29. Nonsurgical Cure of Incompetence of Ileocecal Valve.—Bryant cites a case as proof that an incompetent ileocecal valve may become competent under medical treatment. The treatment he used is not described.

40. **Scurvy in Relation to Diet.**—The extended experimental work done by Cohen and Mendel may be summarized as follows: Experimental scurvy of the guinea-pig is demonstrated at will with suitably chosen diets. Exclusive diets of cereal grains like oats and barley produce the disease. Germinated oats or barley prevent the appearance of scurvy even when fed for comparatively long periods. Scurvy arises on a diet of soy bean flour, even when the latter is supplemented with fat soluble and water soluble vitamins, inorganic salts and cellulose. Small additions of raw milk do not prevent the onset of scurvy. Larger quantities cause the symptoms to disappear. Roughage in the diet plays, if anything, a minor accessory rôle in the prevention of scurvy. This disease is not essentially dependent on constipation as a causative factor though the latter may aggravate the symptoms. Cabbage seems to retain some antiscorbutic properties even when dried. Contrary to certain current statements, highly purified lactose, fed with a scurvy producing diet appears to have no effect on the course of the disease.

45. **Effect of Fruits in Dietary in Scurvy.**—Hess and Unger found that orange juice which had been allowed to age for some months in the refrigerator lost some of its antiscorbutic power. This factor may be extracted from orange juice by means of 95 per cent. alcohol, and is entirely absent in the residue. Artificial orange juice prepared according to the formula of McCollum and Pitz failed to protect guinea-pigs from or to cure them of scurvy. It was also found to lack antiscorbutic power in infantile scurvy. Orange peel possesses marked antiscorbutic potency, and withstands desiccation remarkably well, retaining considerable of this power after being dried for three months. Prunes possess practically no value as a preventive against scurvy. Dehydrated vegetables were found to contain little or no antiscorbutic virtue. This experience coincides with that encountered in relation to human scurvy. As this food is of decided nutritive value efforts should be instituted to improve the methods of dehydrating and of storing so as to obviate this deficiency.

49. **Fat Soluble Vitamin.**—Much emphasis has been placed on the superior value of butter fat as compared with other fats used in the human diet, due to the larger content of fat soluble vitamin in the former. The experiments briefly discussed in this paper indicate some of the conditions which may modify and even eliminate all reasons for this distinction. Lard, vegetable fats, and beef fats on the average, as has been shown repeatedly, do not compare favorably with butter fat. The liquid portion of beef fat as first found by Osborne and Mendel and later by Halliburton and Drummond, and also the fats of certain animal organs are richer in the fat soluble vitamin and in some instances may compare very favorably with butter fat. In general, however, oleomargarins on account of the large amounts of the vitamin poor fats used in their manufacture and in spite of the fact that they are churned with milk and contain some butter fat are not to be considered in the same class as good butter in providing the organism with the fat soluble vitamin. Questions of influence of feed, storage conditions, and temperatures used in the renovation of inferior products and even the method of use of the product in the home must be taken into consideration when depending on butter fat as a sole source of fat soluble vitamin in the dietary. With an abundance of a considerable amount of the vegetative parts of plants in the diet the superior value of butter fat over other fats in the human diet is questionable. In the rat as small an amount as 5 per cent. of alfalfa in the ration provides sufficient fat soluble vitamin for normal growth, reproduction, and the rearing of some young. In the absence of such materials in the diet the superior value of butter fat and in fact its necessity for normal nutrition is not to be denied. Then it becomes an important matter to know how this superior quality of butter fat can be obtained and preserved.

55. **Leukocytes in Influenza.**—During April, 1918, a highly contagious, but comparatively mild infection of the respiratory tract was epidemic at Camp Hancock. Several thousand men in the command were infected, but relatively few were ill enough to be sent to the base hospital. The only fatal case occurred early in the epidemic. A blood culture made on the second day of the disease showed in twenty-four hours a heavy growth of small nonmotile, gram-negative, bacilli—*B. influenzae*. *B. influenzae* was recovered from cultures taken from the lung and spleen. Early in the epidemic, Forbes says, it was noted that leukopenia or at least absence of hyperleukocytosis, was a constant factor, and the leukocyte count was frequently of aid in differential diagnosis. However, the clinical picture of the disease usually made diagnosis easy: Nearly every patient gave as the initial symptoms backache, headache and slight cough or sore throat. Conjunctivitis and a marked injection of the soft palate was noted in 90 per cent. of the cases. In addition, a slight or moderate general adenopathy was often noted. The face was flushed and in a few cases the skin of the thorax presented a mild erythema. In three cases a provisional diagnosis of scarlet fever was made until the blood count showed a leukopenia.

71. See The Journal, Oct. 12, p. 1248, No. 42.

73. **Treatment of Infections and Infected Wounds with Dichloramin-T.**—At present records have been obtained by the authors from 19,040 completed cases in civil surgical practice which have been treated with dichloramin-T during the last fifteen months. These patients have been treated in the Pennsylvania, the University of Pennsylvania, Germantown, Children's and Bryn Mawr hospitals and the accident services of the Midvale Steel Works and the Remington Arms Company. After these fifteen months' investigation they feel that the use of dichloramin-T has definitely improved the results they have obtained in the primary closure of traumatic wounds of the soft tissues, bones and joints. In the treatment of superficial accessible infections dichloramin-T has uniformly given them better results than any other germicide they have employed, and that the method of its application is simpler and the dressings more economical than with any of the other chlorin agents.

The best results with dichloramin-T can only be obtained when actual chemical contact of the germicide with the infecting organism is maintained. To maintain such contact in superficial surgical infections is a simple matter, and in the first few months of the work a satisfactory technic for this class of wounds was developed. In deep and inaccessible infections the problem is more difficult, and the greater part of the fifteen months has been devoted to this aspect. The confidence in the germicidal value of dichloramin-T has so developed that when it does not control infection the authors feel that the chemical contact has not been maintained, the mass of the germicide employed has not been sufficient, or adequate surgical treatment has not been given.

The striking detoxicating effect of the chlorin group of agents which has become common knowledge through the general use of neutral solution of chlorinated soda is just as satisfactory exhibited with dichloramin-T. Dichloramin, unlike the aqueous hypochlorite solution, has no effect on the knots of catgut ligatures and no disintegrating effect on the catgut itself. The occurrence of secondary hemorrhages in wounds treated by the Carrel method was not uncommon in their experience at the American Ambulance. Major Sweet reports that, in his 1,200 cases of major infected military wounds, there was not one secondary hemorrhage.

The authors say that too great stress cannot be laid on the value of dichloramin as a deodorant dressing. The absence of the usual disagreeable odors in their wards, containing cases with fecal fistulas, is a general observation. During the last two months it has been used routinely in the wards of the Oncological Hospital in Philadelphia. Where formerly these putrid, sloughing, malignant tissues were irrigated every two hours with all kinds of solutions, with indifferent success in the control of infection and with a persistence of the offensive odor, now they are packed lightly every six hours with gauze saturated with a 5 per cent. solution of dichloramin-T. Dr. Gordon Saxon reports that not only has the odor disappeared entirely, but the wound infections have been controlled.

90. **Wounds of Chest.**—According to Soltau the chest wound formed on an average 2.5 per cent. of all casualties admitted to the casualty clearing stations and, on occasions, it had risen to 3.5 per cent. To deal properly with cases in these numbers he considered that the following preparations were necessary in a casualty clearing station: 1. A chest team, consisting of a physician and surgeon, who should work in close collaboration, selecting the right type of case for operation, etc. 2. A ward with fifty beds, of which twenty should be fitted with the Fowler elevating frame. (This would allow for the accommodation and retention of cases admitted during forty-eight hours, on an estimated basis of 1,000 admissions a day, which might be expected in active times.) 3. A skilled nursing staff and trained orderlies; apparatus for giving oxygen, preferably Haldane's; if possible, an operating theater attached; immediate access to a bacteriologic laboratory and a roentgenographic outfit. 4. It is necessary also to have a systematized method of note taking and recording.

The mortality had been calculated from returns made from the greater part of the British front during the fighting in 1917. It was impossible to be certain of the death rate in the regimental aid post, but such deaths were practically all in the fatally wounded. At the field ambulance stations it was 7 per cent. In the casualty clearing stations it was 17.18 per cent., that is, 15.9 per cent. in the ninety-three remaining cases. At the base it was about 6 per cent., that is, 4.6 per cent. in the seventy-seven remaining cases. The total mortality in 100 cases which reached a medical unit was therefore 27.5 per cent.

The causes of death were: (*a*) anatomic, (*b*) septic. (*a*) This class included gross lesions, with profound shock and hemorrhage, the complicating lesions involving abdomen and other areas, the multiple wounds, and deaths from edema of the lung and asphyxia. (*b*) The types of infecting organisms at the base were: gas forming organisms, 48 per cent.; streptococci, 40 per cent., and lung organisms, 12 per cent. The infected cases in the front area showed a similar distribution of organisms. The streptococcic infections were the most fatal. In the field ambulance zone the death rate was due entirely to anatomic causes; in the casualty clearing stations it was due both to anatomic and to septic causes, while at the base it was entirely septic in origin. The septic death rate in the casualty clearing stations area was about 26 per cent. of all deaths. Applying the figures given as to mortality, it will be seen that of every 100 men wounded in the chest, about nine die of sepsis.

In the line of treatment, the following points required attention: cleanliness; the combating of shock by careful warming, taking care not to overdo the "réchauffement"; the relief of pain by morphin or one of its derivatives, and by placing the patient in the position which he himself finds most comfortable. The necessity of closing an open wound is mentioned. This is best done by suture, and, in cases in which this is impossible, by most careful plugging. The case should be evacuated to a casualty clearing station as soon as the primary shock is overcome, usually in about three or four hours.

At the casualty clearing station the first essential is to secure rest. Early examination should be confined to determining that there is neither bleeding nor a sucking wound. More detailed examination may follow in a few hours, when an exact diagnosis as to the conditions present, coupled with roentgen-ray localization of foreign bodies, etc., should be made. Sepsis must be continually watched for, both by needling and by observing the constitutional signs. The large hemothorax needs aspiration, which is best done about forty-eight to seventy-two hours after wounding. As regards surgery, the following types of wound might be taken as needing operation: the large open wound or the "stove-in" chest, requiring plastic repair, and closure; the large retained foreign body, when accurately localized; the infected chest, which could be treated either by cleansing and closure or by drainage.

When to evacuate is a constant problem especially in times of active fighting. In quiet times it is better to evacuate the straightforward cases either at the end of three days or else after ten days. The intervening period is the time when sepsis usually appears, and it is better not to let patients travel during that period. In rush times, all wounds unaccompanied by extensive parietal injury, in which the hemothorax is not excessive, may be evacuated within twenty-four hours, provided the primary shock is overcome. After operation, patients should be retained for at least ten days. The open or draining chests travel badly. Patients should not be evacuated within twenty-four hours of aspiration. Soltau says that it is better to hold all patients until convalescent, but the ideal was rarely attainable, and it is often absolutely essential to evacuate early. He emphasizes that surgical treatment concerns only a small portion of the cases, that in these the highest skill is necessary, and that for the remainder the painstaking care of a skilled physician is needed.

92. **Treatment of Gunshot Wounds of Chest in Hospitals on Lines of Communication.**—The main problem in the treatment of these cases, Bradford says, is that of forming an accurate diagnosis: first, as to the exact anatomic condition present; and second, as to the presence or absence of infection. For the adequate treatment of these cases it is essential that these patients should be placed in special wards under the care of a physician and a surgeon working together in close cooperation. If the hemothorax is sterile and small in amount no special treatment is required. Aspiration should be employed in all cases of moderate or large size. The fluid should be removed slowly. The oxygen replacement method is of great value, inasmuch as by this means all the bloody effusion can be removed at one sitting with the minimum discomfort to the patient, provided local anesthesia is employed. In the exceptional cases where clotting en masse has occurred the chest should be opened and the clot removed, the chest being then closed and subsequently aspiration practiced if necessary. In cases of infected hemothorax there should be no delay in the treatment of the patient by surgical methods, such as drainage of the pleura or preferably by cleansing the pleura after the excision of a long length of rib with immediate closure of the chest and subsequent repeated aspiration. The only class of case that admits of delay is that in which the patient presents no symptoms and yet the pleural fluid contains organisms. Some of these patients undoubtedly get well if only treated with aspiration, but in many of these the patient's condition is not really satisfactory, the fluid reaccumulates and it is questionable whether it is not better to treat such patients by opening and cleansing the pleura with immediate closure.

93. **Surgical Treatment of Chest Wounds.**—Tuffier believes that the surgical operations necessitated by the complications which follow wounds of the chest are relatively few. He divides them into two classes: Aseptic complications, which include foreign bodies, hemothorax, pulmonary sclerosis, and ultimately pulmonary tuberculosis; and infections complications, which are constituted by purulent pleurisy, abscess and gangrene of the lungs. He states that foreign bodies should be extracted, after the usual process of localization, only when they cause functional troubles which can be definitely traced to their presence. Tuffier and his colleague Depage advocate a method of treating cases of open purulent pleurisy, based on chemical disinfection of the wound followed by closure of the surgical incision, both in medical purulent pleurisy and in posttraumatic surgical suppurations. (*a*) Treatment of pleural suppuration in unopened cavity comprises three steps: pleurotomy, chemical disinfection and closure. (*b*) Treatment of fistular purulent pleurisy: A bacteriologic examination of the discharge is made by swabs taken from three points: (1) the deep part of the cavity; (2) the edges of the fistula; (3) the skin near the wound. The nature of the discharge being thus established, the treatment is instituted. It comprises three steps, as in the procedure previously described: (1) Débridement and incision of the pleural adhesions; (2) chemical disinfection; (3) closure. When three successive swabs, taken from the depths of the wound, from the edges, and from the neighboring skin, remain negative, the wound is sutured.

94. **Results of Early Surgical Treatment of Lung Wounds.**—For the last two years Duval has treated the wounds of the lungs presenting serious immediate accidents, external or internal bleeding, and opened thorax, by immediate surgical operation on the wound of the lung. For the past year and a half he has operated systematically without compulsion of urgency on certain wounds of the chest to remove the foreign bodies (missile, splinters), to clean surgically the wound of the lung (excision, sweeping suture), to clean the pleura and to treat the wound of the chest wall. Without any immediate surgical treatment the total mortality of chest wounds reaches 30 per cent., not including the soldiers who die in the midposts of the regiments. Through and through wounds, 21.2 per cent.; wounds with shell fragment retained, 30.3 per cent.; wounds with opened thorax, 27 per cent.; wounds with closed thorax, 15 per cent. These figures are based on 3,453 cases.

The authors' personal statistics of last year, including all cases from the field ambulance to the evacuation hospital, all the patients who died without having been operated on, those operated on for serious bleeding or opened thorax, those operated on systematically, and those not operated on, are taken from 161 cases among which there were 27 deaths, a mortality of 16.7 per cent. Of these 27 soldiers who died, 13 were not operated on. They died soon after reaching the ambulance in such bad state that nothing could be done to save them; 148 patients could be treated, 14 died, mortality 10.5 per cent. Among these 148 cases, 29 patients were operated on through urgency, either because they were bleeding severely —16 patients, 9 died—or because the thorax was opened—13 patients, 4 died—the mortality among these being 13. The mortality among the patients operated on through urgency was 44.8 per cent. There were 119 cases which probably would have been treated medically in other ambulances. One hundred and two patients were treated medically because there was no indication for operating; 5 developed empyema; one of them healed perfectly; one died of pleural infection—it was the only death among the 102 cases; the 17 remaining patients who presented no urgent indication for operation but who, according to Duval's personal experience, would probably have developed infection, were nevertheless operated on immediately after reaching the ambulance; the indications for operating being given either by the size of the missile or the injury of the chest wall, fracture of ribs or of scapula, or the importance of the hematoma in the lung. This prophylactic operation consists in: removal of the foreign body; direct treatment of the wound of the lung; bleeding of the pleural cavity; careful excision of the wound of the chest wall. Duval's opinion is that infections are due to the fact that the wound of the lung had not been thoroughly treated, incomplete excision, bits of clothing, or splinters remaining in the wound or in the pleura, and the missile not removed.

95. **Extraction of Projectiles from Pleura and Diaphragm.**—Villéon has abandoned the classic method of thoracotomy in extracting projectiles in the pleura for the simpler method by means of forceps of his own design manipulated under a radioscopic screen and inserted through a small incision. The results thus obtained have been uniformly excellent with a minimum of surgical disturbance and no pneumothorax.

6. **Treatment of Seborrheic Eruptions.**—After studying the effect of giving alkalis in some 300 cases with seborrheic manifestations Barber and Semon have satisfied themselves that their action may be described as specific. It is not contended, however, that administration of alkalis abolishes the necessity for local applications, but it is claimed that this method of treatment hastens in remarkable fashion the clearing of the various eruptions dependent on the seborrheic state, and, provided that the patient be then given an adequate quantity of alkaline salt per diem, relapses will not occur. The best local applications are oily alkaline suspensions of calamine—for example:

℞	Calamine praep	2
	Aqua calcis	8
	Ol. arachis. vel ol. olivae	ad. 30

Most seborrheic lesions are amenable to this application, which should be renewed not less than twice daily, on lint. When oil is difficult to obtain in sufficient quantity, sodium bicarbonate in 2 per cent. solution in water is very useful. It must be applied thrice daily at least, as a soak on lint under jaconet, and should be changed once during the night if the lesions are very acute. At a later stage when erythema and congestion with irritability of the skin surface persist, the part should be covered with lint or linen smeared with Lassar's paste. All hairy parts, with the exception of the eyebrows and lashes, should be close cropped or shaved.

7. **Recruits with Doubtful Heart Conditions.**—Wells endeavored to determine the incidence in 10,000 cases of various diseases which have been supposed to lead to damage of the cardiac valves or myocardium. A history of rheumatic fever was obtained in 19.2 per cent.; chorea, 2.6 per cent.; rheumatism, 16.1 per cent.; growing pains, 26.5 per cent.; tonsillitis, 22.1 per cent.; scarlet fever, 21.8 per cent.; diphtheria, 7.2 per cent.; pneumonia, 5.3 per cent.; influenza, 56.0 per cent.; syphilis, 2.0 per cent.; gonorrhea, 5.95 per cent., and strain, 27.1 per cent.

23. **Cultural Reactions of Anaerobes.**—The conditions of modern warfare are such that the soiling of a wound by earth or by clothing infected with fecal organisms is unavoidable. Further, the short range bullet and the shell fragment bring about a destruction of tissue which gives just those conditions that are most favorable for anaerobic growth. These two factors in combination result in the implantation of anaerobes into a focus of dead tissue and so reproduce in the living body a condition which in certain respects is comparable to an artificial culture.

In estimating the extent of the initial trauma, Henry says, one has to take into consideration, not only the amount of tissue in the wound which is directly destroyed by the missile, but also the amount of tissue in the vicinity and confines of the wound which is damaged through interference of its blood supply either by laceration of its vessels or by the pressure from hemorrhage. It is this extra destruction which makes the wound produced by the modern missile so much more formidable than that produced by the long range bullet of the South African War. Quite apart from the destruction produced by the missile in the wound itself, the early growth of the saccharolytic anaerobes initiates a spreading devitalization process in the surrounding tissues, a process in which gas formation, edema and the appearance of autolytic enzymes all figure as causative factors.

This early period is followed by a second phase which is characterized by the development of the more slowly growing proteolytic organisms. The gas formed in the proteolytic stage of wound infection contains sulphuretted hydrogen and certain volatile bodies, and it is these which give rise to the heavy penetrating fetid odor which is such a striking clinical feature of anaerobe infected wounds. The blackening which develops under artificial conditions in meat cultures, and which indicates the formation of a sulphid of iron, is likewise to be found in wounds.

The third phase in anaerobic infection consists in the development of a toxemia, the exact nature of which is as yet undetermined. The clinical picture produced is chiefly that of a rapidly increasing circulatory failure in which death may result so abruptly as to give the impression that it has been caused by pulmonary embolism. But not a single example of the latter condition has been met in a series of over 600 necropsies on men dying from gunshot wounds. This state of rapid circulatory failure has none of the clinical features that are usually associated with acidosis, nor is there any clear laboratory evidence that the local production of acid in and about an infected wound may alter the general reaction of the circulating blood and so cause an acid intoxication of the person. Therefore, the toxemia is believed to be caused by the absorption of some degradation product of protein rather than of carbohydrate, and that it is a toxic protein derivative rather than acid which brings about the abrupt shocklike collapse of the circulation.

The last stage of anaerobic growth is that of successful bacterial invasion of the blood stream. In the majority of cases this inroad occurs just at, or immediately preceding, the death of the person.

25. **Perforating Wounds of Abdominal Viscera.**—Certain facts regarding penetrating wounds of the abdomen on which the clinical evidence is at present somewhat obscure were worked out experimentally by Drummond and Fraser. The first question considered was that of, to what extent can perforating wounds of the intestine recover without operation? The authors used hares, cats and dogs in this work. They found that bullet wounds of the intestine can be very closely simulated by cutting the intestine wall with small sharp scissors. Single artificially made wounds of small size recover, irrespective of the portion of the intestinal tract in which they may occur. Multiple small experimental wounds occasionally undergo spontaneous recovery, but, if too numerous, are fatal.

The second question considered was: If perforation of the intestinal tract occurs, is there any one portion of the intestine that has a greater tendency to spontaneous cure than another? It was found that wounds of the ileum show a greater tendency to spontaneous recovery than any other part of the intestinal tract. In the absence of omentum, spontaneous closure of intestinal wounds occurs by adhesion of neighboring coils of intestine with a plastic peritonitis. Spontaneous closure is hastened when omentum is brought into contact with the injured part. The omentum is at first widely adherent over the injured part. At the end of three days the points of adhesion are limited to the actual intestine perforation. At the end of seven days a vascular anastomosis has occurred between omentum and intestine wall. Mucous membrane at the point of injury remains prolapsed for about a week, in this was to some extent blocking up the aperture. It is eventually replaced by a plug of fibrin. At the site of perforation there tends eventually to be a small sacculation of the mucous coat through the unsupported gap in the muscular tissue. Large areas of stomach wall can be replaced by omental tissue, but restoration of the stomach epithelium does not appear to occur.

26. **Gas Gangrene of Muscle.**—As the result of studying a large number of cases of gas gangrene, Emrys-Roberts and Cowell recognize three main clinical types: *A*. The common type which occurs in wounded lying out twelve to twenty-four hours, or which develops a few hours after the first operation. *B*. The fulminating type where the patient, if untreated, may be dead in a few hours. *C*. The delayed type with a slow onset, so that the condition only becomes established several days, or even weeks, after the date of wounds. In the established cases, the clinical picture is so striking, with the pungent smell, color changes of dead muscle, and grave constitutional symptoms, that the diagnosis never remains long in doubt. It is in the earliest stages of the common type that the importance of immediate diagnosis lies. Here, if attention is paid to the local physical signs found in the wound, a diagnosis can be made before general symptoms have had time to develop. There are two types of wound of muscle in which gas gangrene is especially liable to develop. First, in deep penetrating wounds, with or without fracture of the bone, in which the main vessels may or may not be involved; and, second, an extensive surface wound, where gross laceration of the muscles has been produced, and where large amounts of infective material, such as dirt and fragments of clothing, have been carried in. The authors describe, in detail, the macroscopic and microscopic appearances of the infected muscle at different levels.

The belief is held that gas gangrene of muscle is essentially a manifestation of anaerobic infection. Extensive trauma is an important etiologic factor, as is also the symptom complex of shock, hemorrhage, and exhaustion. The toxins evolved by the growth of the anaerobes contain a myolytic substance—an acid, and, possibly also, deleterious disintegration products; in addition, they possess antichemiotactic properties toward leukocytes. The lytic changes in individual fibers are traced through the following stages during the process of advance: Blurring and eventual loss of cross striations, exaggeration of longitudinal striae, swelling of the fiber, changes in staining properties, and the formation of fluid containing perifibrillar spaces, in which are suspended the toxins and bacilli; fragmentation of the fiber, with marked lysis (which may proceed to complete disintegration); and, finally, phagocytosis by the leukocytes at and near the wound surface. Lytic changes also take place in the muscle fibers of blood vessels, though these are comparatively late phenomena. The capillaries owing to their lack of muscle constituents escape, and, as the result of free anastomoses, the blood supply is generally maintained, and diapedesis of leukocytes provided for. The formation of a fibrinous leukocytic layer at the wound surface is characteristic. The greater the number of leukocytes present, the greater the degree of neutralization of the toxins, and vice versa. The presence of this layer is associated with the absence of pus.

In cases in which the stage of recovery and arrest of the process is reached, the fibrinous leukocytic layer assumes the character of a white line of demarcation, separating dead muscle on the one hand from living muscle on the other. Subsequently this layer is cast off in the form of sloughs, and true granulation tissue takes its place. During the stage of arrest of the process the lytic changes are so abbreviated or compressed in the case of individual fibers, that the change from living striated fiber to the last stage of lysis and phagocytosis is abrupt. The production of gas is always a late phenomenon, except in the fulminating type of case. Its action is purely mechanical, and may lead to ischemia by compression within fascial sheaths, thus assisting and hastening the infective process. Although anaerobic bacilli can be demonstrated in apparently normal muscle well ahead of the process of gas gangrene, they do not assume a pathologic rôle, except when, in case of very grave infection, they are associated in the process of a bacteremia and may give rise to secondary foci. Vascular changes, apart from the effects of trauma, are absent in the advancing edge of the gas gangrene process. Regeneration of muscle fiber is extremely improbable.

28. **Fatty Tissue Transplantation Into Spleen.**—Experimental work was done by Matsuoka to ascertain whether there is any difference in the fat of transplanted fat-cells from the bone marrow and from lobulated fatty tissue proper, that is, from so-called primitive fat organs. With this end in view he autoplastically transplanted fat from the peritoneum and from the cervical region into the spleen. Autoplasty of lobulated fatty tissue from the peritoneum into the spleen was

always successful. Various regenerative processes appear in the fat-cells as early as three days after transplantation. Healing over of the transplanted fatty tissue is much more rapid than in the case of bone marrow; at the same time all fat-cells of the transplanted tissue are well developed.

Autoplasty of the so-called primitive fat organ into the spleen was also successful. Peritoneal connective tissue transplanted with the fatty tissue is converted into fatty tissue after transplantation into the spleen. Epithelial-like fat-cells of the so-called primitive fat organs are converted into common signet-ring shaped fat-cells after autoplasty into the spleen. After transplantation of fatty tissue into the spleen it is evident that connective tissue cells of the spleen may be changed into fat-cells by heterogeneous regeneration during the healing over of the graft.

From these experiments with fat transplantation it is apparent that fat cells of any kind may originate by indirect metaplasia of connective tissue cells, and that there is no conclusive evidence of the presence of so-called *sui generis* fat-cells.

29. **Action of Micro-Organisms on Transplanted Bone Marrow.**—Matsuoka infected rabbits with tubercle bacilli in order to cause chronic irritation of the bone marrow. In two cases which were examined eighty-nine and 112 days respectively after the subcutaneous injection of tubercle bacillus emulsion, the mesenteric glands showed necrosis and secondary fibrous induration. Disseminated, miliary, and also conglomerated tubercles and tuberculous pneumonia were present in the lungs. The spleen exhibited miliary, partly caseated tubercles, consisting mainly of epithelial cells. There was thus a general widespread tuberculosis partly brought about by hematogenous infection. The transplanted bone marrow in the spleen consisted principally of well developed fatty marrow, in a small part of which islets of marrow cells were to be seen between the fat cells. In another part, however, the bone marrow was diffusely cellular with uniform hyperplasia of the various medullary cells. The bone marrow in the femur had the same appearance as the transplanted bone marrow in the spleen.

The animals were dissected 185 and 190 days after transplantation, at which times, after simple autoplasty into the spleen, no evidence of myeloid deposits of the spleen substance is present. Tuberculous infection did not result in the appearance of myeloid cells. It is evident from these observations that even with such slight general functional irritations, as occurs in tuberculous infection, bone marrow transplanted autoplastically into the spleen in moderate amounts has the same reaction as the remaining untransplanted bone marrow. This view is also in accordance with the biologic healing up of the graft in the spleen.

30. **Differentiating Between Endameba Histolytica and Endameba Coli.**—With the intention of facilitating the rapid recognition of the ameboid form of the parasite, Cutler and Williamson have employed a 1:10,000 solution of neutral red in 0.85 per cent. sodium chlorid solution. A loopful of feces is emulsified in a drop of the neutral red solution on a glass slide. The preparation is covered with a coverslip and examined with one-sixth inch objective and No. 10 eyepiece. A warm stage is an advantage, but is not essential. In such a preparation the vegetative form of *E. histolytica* takes up the neutral red, and the stained amebas can readily be seen and recognized. The pink dye is uniformly distributed throughout the endoplasm, while the ectoplasm remains unstained. *Endameba coli* is not stained and appears as a light gray body. The method forms an easy and satisfactory means of differentiation between the two micro-organisms.

35. **Controlling Fragments in Gunshot Wounds of Jaws.**—Pickerill maintained that there is, or should be, no best method of controlling fragments. Each case should be treated individually, according to its requirements. Control and not absolute immobilization of the fragments should be the aim of any method of treatment. The utilization of function and perhaps slight mobility of the fragments from as early a time as possible is the best stimulus to union. A conservative line of control should be adopted whenever possible; that is, loose teeth and small fragments should be retained and controlled with function rather than be sacrificed to obtain a quick but inferior result.

37. **Susceptibility of Antiscorbutic Principle to Alkalinity.**—The experiments made by Harden and Zilva show definitely that alkalinity has a very deleterious effect on the antiscorbutic potency of orange juice. Most antiscorbutic vegetables are either neutral or very slightly acid, and any culinary manipulation which entails alkaline treatment, even to a slight degree, will be instrumental in the destruction, if not of the entire, at least of a significant part of the antiscorbutic potency of such vegetables. When orange juice was made twentieth normal alkaline it was found that it did not prevent or delay the onset of scurvy.

38. **Prognosis in Trench Nephritis.**—Evidence presented by Dyke seems to indicate that the condition known as trench nephritis differs little from nephritis as met with in civilian practice except in the greater frequency of its occurrence, and that it is either a primary acute nephritis or an exacerbation of preexisting disease, induced by fatigue and exposure.

52 *Tuberculous Cavities with Few Bacilli. C. Mantoux.—p. 307.

48. **Familial Hypertrophic Neuritis.**—Marie and Bertrand report with eighteen illustrations some interesting histopathologic findings at necropsy in two cases of familial hypertrophic neuritis.

49. **Electrically Induced Nystagmus.**—Bard discusses the nystagmus and other phenomena induced by placing on the temples the electrodes from a battery. The differences between the phenomena thus induced and those from thermic stimulation of the labyrinth throw light on the mechanism of the nystagmus, etc., under these conditions, as he explains in detail. The results from the two methods usefully supplement each other.

50. **Albuminuria in Soldiers.**—Merklen found complications on the part of the kidneys directly after acute infectious diseases in 17 per cent. of the men examined, irrespective of whether the men had been serving at the front or had never reached the trench line. In six of eighteen men the albuminuria had developed after acute tonsillitis. There was a history of some old acute infectious disease in 40 per cent. of the eighty men from the front and in 50 per cent. of the thirty others. In 22 per cent. there was primary nephritis

occurring in previously healthy men. In two of the men the albuminuria developed after antityphoid vaccination. Merklen's final conclusion is that chronic albuminuria which may be well borne in civilian life is extremely liable to give trouble under the stress of military life, even of limited service.

51. **Signs of Adhesive Pericarditis.**—Lenoble concludes from his study of eight cases of adhesive mediastinitis that there are no pathognomonic signs of it. Operative measures are called for when access to the adhesions is possible. The diagnosis is facilitated whenever certain radiographic fixed shadows show a special intensity. Also by the thickening of the pleura detected on attempting to puncture it, the needle meeting resistance as if from leather or thick cardboard.

52. **Tuberculous Cavities with Few Bacilli.**—The *Annales* has joined the *Lyon Chirurgical* and a number of other French, Italian and Swedish Journals which now are giving a brief abstract in English of each article. The abstract accompanying Mantoux' article is given herewith complete. "There are some chronical cavitarious tuberculous patients far from any evolving push, of which the repeated examination of the spits, even preceded by homogeneisation and centrifugation, is unfit for disclosing the presence of the Koch-bacillus; the only inoculation to the guinea-pig identifies those cavitarious paucibacillarious (with few bacilli) tuberculoses. It is necessary, with every sick suspected of tuberculosis, to have recourse of the triple stethacoustical, bacteriologic and radiologic examination. The three methods are equally indispensable; one corrects the errors of the other; an examination of a tuberculous is incomplete, if it does not rest on this diagnostical tripod."

53. **Spirochete Bronchitis.**—Nolf and Spehl have encountered eight cases of bronchitis which resembled Castellani's bronchospirochetosis and also Violle's spirochete bleeding bronchitis but differed from both by the extremely fetid character of breath and sputum. There was a hemorrhagic tendency only in one of the cases. The bronchitis was primary in six of the eight cases, and one of these men died. The onset was stormy, with progressive weakness, dyspnea and cyanosis, and numerous spirochetes in the sputum. The duration of the disease was over a month at least; in the fatal primary case, seventy-three days, and in the two secondary cases, ten days and two months.

56. **Night Blindness in Soldiers.**—Danis reviews the literature on hemeralopia and states that he has encountered it in 7.52 per cent. of 2,700 Belgian soldiers with eye disturbances of various kinds. There seems to be a recrudescence of it in the men on active service. Alcohol is totally proscribed on the Belgian front, and the coffee is made weak, but the men smoke a great deal. No central scotomas were discovered. Probably the hemeralopia in many cases is merely the revealing under army conditions of an old unsuspected tendency to night blindness, but there is no doubt that the physical and emotional stress of the war has sometimes induced essential hemeralopia by some disturbance in the local circulation, rendering the retina unable to adapt itself in the obscurity of the night. These men should be spared night service, but simulation must be guarded against.

57. **Wounds of the Lung.**—Lefebvre's long study of the immediate complications of wounds of the lung concludes by urging immediate suture of the pleura as almost the routine procedure, like a laparotomy for an abdominal wound. Surgical closing of the breach in the wall immobilizes enough to favor hemothorax, and the compression from this may check further hemorrhage. Moving a man wounded in the chest is even more serious for him than with an abdominal wound. If possible, he should be kept for two or three days. Shock in men wounded in the chest simulates grave anemia. Repose and immobilization are the best treatment. If the heart is much displaced, it may be advisable to puncture. It may prove possible to arrest hemorrhage by artificial pneumothorax. The Italians have used this method considerably for war wounds of the chest, and laud the results obtained. It seems logical to get rid of the extravasated blood, liable to set up infection, and replace it with a sterile artificial pneumothorax to keep up the compression. If the hemorrhage persists, thoracotomy and suture of the lung are indicated. With increasing experience this will probably be done earlier to arrest hemorrhage and not be left for the last resource. The immediate advantages of suturing the pleura are so great that the danger from leaving a foreign body in the cavity can be overlooked. Local anesthesia or simply morphin is preferable to general anesthesia. The ribs can be spread apart, to enlarge the opening, resecting the ends of a fractured rib.

58 *Microbic Associations in Meningitis. Condat.—p. 449.
59 Acute Tuberculous Nephritis. L. Petitpierre.—p. 467.
60 *Phlegmon in the Orbit. Condat.—p. 473.
61 Present Status of Acrocephaly. J. Comby.—p. 476.

58. **Mixed Meningitis.**—Condat reviews the experiences with 47 recent cases of meningitis in Comby's service. She has compiled others, bringing the total to 168 cases, with mortality of 31.5 per cent. A number of the patients were young infants who always present an exceptionally high death rate. All but 11 of her 47 cases were meningococcus cases, with 25 per cent. mortality. Treatment was always by intraspinal injection of 15, 20 or 30 c.c. of antimeningococcus serum, according to the age of the child, whenever the lumbar puncture fluid looked turbid. If the meningococcus is found, the injection is repeated the next day and again after forty-eight hours. Two injections answered the purpose in 3 cases; three were required in 12 and four in 6. In 9 cases from five to ten injections were made; in 3 cases a tardy relapse or recurrence compelled a new series of injections. No special precautions were taken against serum sickness and except for an occasional rash or slight arthralgia there were no mishaps from it. She keeps up the serotherapy so long as the fluid is turbid; recovery followed in some cases which had seemed absolutely beyond relief. To start the serotherapy early is more important than the type of meningococcus involved. Everything should be done to simplify it and render it available for every practitioner. Any attempt to mix serums from different strains merely renders the serotherapy more complicated. This should be left to institutions. Even at the best it may delay proper treatment.

60. **Phlegmon in Orbit.**—There had been first a rhinopharyngitis, then ethmoiditis and then the phlegmon in the left orbit. The general condition kept good and the pus broke through spontaneously with complete recovery during the several months to date.

69 Periarterial Sympathectomy in Raynaud's Disease. L. Veillet.—p. 571.

62. **Tardy Relapses of Meningitis.**—Netter says that among 350 meningitis patients, 1.14 per cent. had a relapse in from one to nearly three months after apparent recovery. In two infants intercurrent measles probably brought on the relapse. Some of his and others' cases suggest that antityphoid vaccination may produce a reaction in the organism which might favor the proliferation of otherwise harmless meningococci slumbering in the nasopharynx. In certain exceptional cases, the reaction to an antityphoid injection may simulate meningitis. In one case meningitis was soon followed by paratyphoid B and this in turn by meningitis again, with final recovery under serotherapy. Sainton reported syncope after

an intravenous injection of antimeningococcus serum, which required artificial respiration to revive the patient.

67. **Hemoglobinuria in Malaria.**—These two communications describe several cases of malarial *bilieuse hémoglobinurique* and explain the disturbances as the result of a kind of auto-anaphylaxis. This auto-anaphylaxis is of a physical nature, and it is the initial phenomenon of the hemoglobinuric jaundice. The massive destruction of red corpuscles occurs suddenly and rapidly and the blood pressure falls, but the reds that escape display normal resisting powers, and no hemolytic substance can be detected in the serum nor in extracts of various organs. The liver and kidneys were found apparently sound. A small dose of quinin may start the auto-anaphylaxis in those hypersusceptible to it, but it occurs in others in the absence of quinin. The practical conclusion of the articles is that *bilieuse hémoglobinurique* should be treated by anti-anaphylaxis measures such as have proved effectual under other conditions. The blood serum taken during a malarial attack might be used in the anti-anaphylaxis. This might serve to "consolidate the hemolytic complex" as Widal, Abrami and Brissaud have accomplished in paroxysmal *hemoglobinuria a frigore*. One of the patients recovered but two others died, the massive destruction of the red corpuscles having induced extreme anemia with fatal anoxemia. Death occurred more rapidly than is the case from anemia alone.

68. **Intravenous Injections of Hexamethylenamin.**—Loeper and Grosdidier determined the relative harmlessness of hexamethylenamin in injections by the vein in rabbits and then they applied it in typhoid, pneumonia, nephritis and liver disease. The action of the drug by the vein, they say, is infinitely superior to that by subcutaneous injection or by the mouth. It had an unmistakably favorable influence on the temperature, the general condition and on kidney functioning. In fifteen pneumonia cases all were improved and cured; in five the disease was aborted, defervescence occurring the following day. In septic bronchopneumonia the temperature declined more gradually but the general condition improved. Very slight influence was noted in the pleural streptococcus cases and it was inconstant in the secondary streptococcemias. Rabbits bore perfectly injection by the vein of 0.5 gm. per kg. and man seems to bear without harm 1.5 to 2 gm. The dose was 0.25 gm. to 1 c.c. sterilized water, the solution prepared cold, with intermittent sterilization. The volume introduced should not be over 6 or 8 c.c., that is, about 2 gm.

The same treatment was applied in serofibrinous pleurisy with good effects, slow but progressive. The results seemed to be the same when the drug was injected directly into the pleural cavity. In tuberculosis, they say that a series of twenty injections seemed to induce *très réelles améliorations*. One young soldier with nephritis and dropsy, pneumonia and sputum swarming with tubercle bacilli was given 21 gm. of the drug in two series of seven injections, and notable improvement followed. They add that of course this medication is only palliative, but the experiences to date indicate that it acts on the general reactions, the febrile, the toxic and the septic. It is a sedative but without depressing action, and it seems to reduce the intoxication from the infection wherever the infectious process may be located.

70 *Disturbances in Nails after War Wounds. A. Le Dantec.—p. 215.
71 *Operations for Wounds of Nerves. A. Hesnard.—p. 218.
72 Pseudo-Tuberculosis of Peritoneum. J. Vitrac.—p. 224.
73 Suggestions for Rural Hygiene. Darbouet.—p. 226.

70. **Finger Nail Sign of Irritative Neuritis.**—Le Dantec has frequently noticed as a trophic disturbance in the finger nails after a war wound of the arm, the development of a roll of flesh under the outer end of the nail. This *bourrelet sous-unguéal* is a warning of the presence of some scrap of pro- jectile or gravel in the tissues. The matrix, the bed of the nail and the nail itself all seem to be subject to a manifest process of hyperplasia. Percussion of the nerve its entire length will generally locate the foreign body, the cause of the trouble. This is usually where the nerve is embedded in cicatricial tissue. The percussion induces an intense tingling pain to the tip of the fingers or toes. He has succeeded in releasing the adherent nerve by daily potassium iodid ionization of the spot, the electrodes applied to both sides of the limb, supplemented by massage and exercise to break up gradually the adhesions. In one case he abolished the pain by injecting alcohol (70 per cent.) into the adherent cicatrix. As the cause for the irritative neuritis is removed, the protuberant flesh under the nails disappears with it.

71. **War Wounds of Nerves.**—Hesnard reviews the indications and contraindications for operations on peripheral nerves as determined from the immediate and remote experiences at the Bizerte *centre neuro-psychiatrique* of which he is chief. Good results were seldom obtained when the interval was over four months, and the best outcome was with intervals of from one up to four months. The operation might even be done the very day of the war wound. He thinks that the danger of an aseptic operation near a recent or slightly infected wound may have been exaggerated. He has witnessed again and again the excellent reunion of surgical wounds made for intervention on nerves a few centimeters from a war wound in evolution and previously infected. But such haste is not indispensable, and he advocates operating regardless of the interval when clinical examination shows the absence of complete or very pronounced degeneration of the wounded nerve and the muscles which it innervates. By "degeneration" he does not mean the degeneration response to electric tests. This may be encountered with superficial and curable injuries. Only anatomic neuromuscular degenerescence indicates that the nerve is lost beyond redemption, and this may take eight or ten months; in some cases up to one year or three years. Some stop short of complete degeneration and finally recuperate spontaneously. Suture after the nerve had been completely severed resulted in a cure in two out of fifteen cases, and improvement only in two other cases. Certain nerves recuperate earlier and more completely than others; in this order he lists the radial, the external sciatic, the ulnar, the internal sciatic, the median, and the trunk sciatic nerves.

79 *Radium Treatment of Cancer of Prostate. G. Marion.—p. 335.
80 *Transactions of Urologic Conference.—p. 337.

74. **Kidney Stones in Soldiers.**—This report from a *centre urologique* states that in the total of thirty-four cases of kidney stones encountered in the course of three years, the kidney was infected in all but five. The remarkable clinical latency of stones in the kidneys as long as the kidney is not infected is shown by many of the cases. The unhygienic conditions at the front predisposing to autointoxication, and the jolting over rough roads, etc., damage kidneys already impaired by the presence of stones, and if an infectious process is set up this first attracts attention to the kidneys. The experiences related teach the importance of radiographing the whole urinary apparatus when there are even vague complaints in respect to the kidneys. Ambard's ureosecretory constant showed a marked turn for the better after removal of the stones.

75. **Fistulas of the Urethra.**—Cathelin devotes nearly fifty pages to analysis of the different war wounds of the external genitals and the best means for repair. His article is accompanied by twenty-seven illustrations, and he emphasizes the necessity in operating always to be ultra conservative, as every minutest scrap of skin is extremely important for the plastic operation later. Even when the penis has been almost completely severed, he has succeeded in getting it to heal in place. He gives minute directions for the various plastic operations and calls attention in particular to his method of curing a fistula by turning in the skin. (It was briefly described with an illustration in The Journal, Aug. 17, 1918, p. 606.) He has applied it in thirteen cases of war fistulas with complete and rapid cure in a few days, the men soon

returning to service. In nine cases of inflammatory fistulas the cure was prompt and complete in seven, but the tissues were too pathologic in the other two cases. This technic is applicable to fistulas anywhere, in the intestine, salivary glands, bladder, etc. He regards it as destined to a future, "a great progress which we owe to the war." This *inversion cutanée avec section bipolaire* is the ideal method, he reiterates, for treating a fistula into the urethra as it does not encroach on the urethra itself at all, and the cure is permanent without ulterior stenosis. He warns that a retention catheter is disastrous after these autoplastic operations. The intermittent use of the catheter answered the purpose in his cases.

76. **Bilharziasis of the Bladder.**—Desnos reports a case in which there have been no further symptoms during the two years since he gave a ten months' course of diathermy treatment. The cystoscopic findings now show clinically normal conditions in the bladder. The application of the high frequency current was somewhat painful, so that he could not cauterize more than ten or twelve of the minute vesicular elevations in the bladder walls at one sitting. The only danger with this treatment is the possibility of hemorrhage as the little eschars drop off in about two days. There was only slight hematuria in his case.

Marion's patient complained only of his right kidney, which proved to be absolutely sound. Fifteen little bleeding elevations were seen in the bladder walls, while the ureter urine was normal on both sides. The patient clamored for an operation on his right kidney but Marion compromised by resecting the little polypous bunches through a suprapubic incision, and cauterized the site of each. At once all symptoms subsided and the cure has been complete to date.

79. **Radium Treatment of Cancer of the Prostate.**—Marion punctures to the prostate with a hydrocele trocar, a little to one side of the median line of the perineum, guided by the finger in the rectum. The radium tube, mounted on a silver wire, is then introduced in place of the trocar. The same procedure is repeated on the other side. In forty-eight hours after withdrawal of the radium tubes the puncture holes are healed and the patient can get up and return to business.

80. **Conference of Army Urologists.**—The men in charge of the French "urologic centers" held a conference recently at Paris. Two questions had been appointed for discussion; the treatment of war wounds of kidney and ureter, and autoplastic procedures for traumatic fistulas of the urethra. The transactions are reported here in full. The leading address on the second subject is summarized in Abstract 75 above.

81 *Scarlatinal Endocarditis. Nobécourt.—p. 429.
82 *Malarial Mammitis. H. de Brun.—p. 430.
83 Extraction of Projectiles in Skull. H. Béclère.—p. 431.
84 Sulphur-Oil Injections for Psoriasis. L. Bory.—p. 432.

81. **Scarlatinal Endocarditis.**—According to Nobécourt's experience, scarlatinal endocarditis is more liable to run into a chronic phase in children than in adults. In seven cases in soldiers under 24 the heart sounds returned to normal in from thirty to fifty days in five of the men. Others have reported similar experiences, showing about 28.5 per cent. left with persisting valvular trouble. Tardy tachycardia may occur after scarlet fever with or without the endocarditis. In one soldier acute articular rheumatism developed at the twenty-seventh day of scarlet fever, and mitral endocarditis followed, with pericarditis, pleuritis and phlebitis in left leg. Another had acute articular rheumatism the fifth day of the scarlet fever, mitral endocarditis the seventh, and acute nephritis the thirtieth. Scarlatinal endocarditis is of the simple type. The best testimony to an infectious endocarditis is the existence of severe secondary infections, a tardy infectious syndrome. In conclusion he reiterates that the agent of acute articular rheumatism and the agent of scarlet fever can determine clinically identical affections of the heart.

82. **Malarial Mammitis.**—De Brun has encountered sixteen cases of a characteristic swelling and pain in the mamma on one or both sides in soldiers with a severe form of malaria, or the mammitis may develop as the first manifestation of the malaria. The men button their suspenders farther along on that side, and this "suspenders sign," or the pain from lying on the breast in sleeping may be the first thing to call attention to the malaria. The mammitis persisted for six and for eight months in two of his cases; only exceptionally was it as brief as twelve and fourteen days. No tendency to sclerosis later was detected in any instance. All the men had ordinary tertian malaria. In one the mammitis developed three months after contracting the malaria; in one not until after fourteen months. No action on the mammitis was apparent from quinin, even pushed with 2 gm. a day, and the usual sedatives had little effect in reducing the pain.

88 *Rupture into Peritoneum of Echinococcus Cyst. F. Dévé.—p. 125.
89 *Laws Regulating Healing of Skin Wounds. A. Lumière.—p. 168. Conc'n.

85. **War Wounds of Wrist.**—The indications for operation are deduced by Combier and Murard from the ultimate results of their treatment in twenty-seven cases. With a suppurative process, the effects of treatment are not very brilliant. In their four cases of this kind, amputation had to be done later in one, but one of the others has good use of his hand seven months after the total carpectomy. It was done the twenty-eighth day after the seton wound of the left wrist.

86. **Conservative Treatment of Wounds of Knee.**—Delmas is an advocate of extreme conservatism in treatment of wounds of the knee. He says that Willems' method of immediate and active mobilization of the knee (described in these columns on page 1009, abstract 23), has resulted in more rapid and more perfect cures in the cases in which asepsis can be counted on, than with other methods. Otherwise, in simple cases Delmas' practice is a lateral arthrotomy. It is easy then to open up the joint by severing the patellar ligament if the lesion is found extensive.

87. **Amputation of the Thigh.**—Martin discusses the indications, the technic and the results in fifty-three cases. He says it is not a grave operation when done correctly and rapidly under general ethyl chlorid anesthesia. The shock of the wound is the main thing; the operative shock is insignificant in comparison. The prognosis depends on the wound or the gas gangrene compelling the amputation. The latter, he declares, does not aggravate the prognosis, but the amputation cannot cure unless it removes the septic focus entire. Before September, 1915, he had to amputate for septicemia in seventeen cases but since then only in eight cases. The mortality in the first group was 41 and in the second 12.5 per cent. Salvation with a penetrating wound of the knee lies in immediate extensive exploration of the knee and early resection if demanded. A rebellious purulent arthritis calls for amputation when the reactions of the organism demonstrate that the arthritis is getting the upper hand. The application of these principles has brought his mortality from 44.4 per cent. down to zero. When septicemia after a war wound of the leg or thigh shows no signs of yielding to treatment, he bows to the inevitable and amputates in time, and thus has brought the mortality down to zero in this category also.

88. **Rupture of Echinococcus Cyst in Biliary Apparatus.**—Dévé refers to what he calls *choleperitoine hydatique*, that is, a torpid effusion in the abdomen consecutive to the accumulation in the peritoneal cavity of nonvirulent bile escaping from a ruptured echinococcus cyst in the liver. He devotes forty-two pages to the various aspects of this phenomenon and its consequences. The possibility of an echinococcus cyst as the cause of the accumulation of bile in the peritoneal cavity should never be forgotten. He warns that multiple cysts should always be suspected, and the permeability of the biliary passages verified before concluding the operation. When an accumulation of bile in the peritoneum has become encysted, it is dangerous and useless to attempt to remove it. But it is important to destroy any elements liable to start new cysts, and he relies on ether for the purpose, convinced that it has a specific destructive action on the scolex. Copious ether lavage of the peritoneum is thus advisable when a cyst

In another case the man of 30 had ten operations for papillomas in the bladder in the course of nearly six years. The tumors finally recurred in a malignant form. After the tenth operation, roentgen treatment was given through a temporary bladder fistula, and the man has had *no recurrence* during the nine years since to date. Eight twenty-minute exposures were given in the course of eight days. A medium hard tube was used, with a total of 17.5 H units; distance, 22 cm. The exposures were preceded by local anesthesia and morphin. The general practitioner must bear in mind the marked tendency of benign bladder tumors to develop early into cancer, and not waste too much time on symptomatic treatment of hematuria and cystitis. The operation must be extensive and radical, and the patient must be kept under regular control for the first few years so that any recurrence may be detected and removed at once. All bladder tumors seem to possess a potentially malignant character. Only 12 of the 49 patients were women; the youngest was 29, the oldest 80. The immediate postoperative mortality was 45 per cent., but 3 of the 7 cancer patients who survived the operation are still living, nine, seven and six years to date. Of the 20 patients with apparently benign tumors, no less than 9 have died since, all from malignant disease except 2.

Norsk Magazin for Lægevidenskaben, Christiania

126 *Idiopathic Dilatation of Esophagus. F. Harbitz.—p. 841.
127 *Thalamometer. G. Ræder.—p. 862.
128 *Chronic Stenosis in Larynx or Trachea. V. Uchermann.—p. 872.
129 *Syphilis of Internal Organs. K. Nicolaysen.—p. 890.
130 *Aplasia or Dystopia of Kidney. G. Schaanning.—p. 901.
131 *Mechanism of Acute Duodenal Occlusion. S. Høyer.—p. 914.

126. **Idiopathic Dilatation of the Esophagus.**—Harbitz describes the clinical and necropsy findings in three cases of this anomaly which he classes with Hirschsprung's disease and hypertrophy of the pylorus in infants. All three seem to be the result of some congenital abnormality, possibly a tendency to functional atony of the walls, with abnormal conditions in the vagus nerve causing spasmodic contraction of the bowel, pylorus or cardia. The patients in the three cases reported were men of 34, 40 and 27, and they had been having noticeable dilatation of the esophagus for eight, four and seven years.

127. **To Measure Depth of Anterior Chamber.**—Ræder calls the instrument described, with illustrations, the thalamometer.

128. **Operative Treatment for Stenosis in Trachea and Larynx.**—Uchermann reviews the different methods in vogue for treating chronic stenosis in trachea or larynx and expatiates on the unsatisfactory results often obtained with these needlessly extensive and comprehensive operations. All that is necessary is to act on the exact point of the traumatic stenosis, stretch it, and leave the rest of the organ intact. He accomplishes this by introducing a nickeled cylinder on a handle. It is introduced from the cannula opening, just below the stenosis, and does not extend above it. No force is used to introduce it as the stenosis is severed beforehand on the median line. The blunt-tipped herniotome with which this is done does not incise the skin except the buttonhole for its introduction. Since 1909 he has applied this treatment in five severe cases, all but one sequels of diphtheria. The patients were children from 2 to 4 years old and one young woman. The latter had worn a tracheotomy cannula for seven years after diphtheria at the age of 4. After its removal the tracheostomy could not be closed on account of the stenosis. All were completely cured with this slitting of the stenosis tissue plus retrograde dilation. He makes a point of removing the cylinder and the cannula every morning to allow the patient a chance to cough up mucus. They are then replaced at once.

129. **Visceral and Pulmonary Syphilis.**—Nicolaysen writes that unquestionable syphilis was found in 10.5 per cent. of 1,137 cadavers before 1906, and in 6.4 per cent. of the 2,695 since then. In a case described in detail the man of 51 had presented symptoms at 40 diagnosed as beriberi at the time. Later came ascites, with dyspnea, dulness over both lungs at the rear, and edema, but no fever; occasionally there was vomiting of brownish masses. Necropsy showed the brain, heart and large vessels apparently normal but a large gumma was found in one lung and smaller ones in the liver, pylorus and around the spleen, plus a fibrous orchitis. No signs of tuberculosis anywhere.

130. **Congenital Kidney Anomalies.**—Schaaning states that the solitary kidney and the displaced kidney are peculiarly subject to disease. He reports a case of each. Winter found pathologic conditions in sixty-five of 235 solitary kidneys. The displaced kidney may press on the bowel, bladder or genital organs and interfere with their functioning or induce neuralgia, etc., from pressure on nerves or vessels. Twelve cases of chronic renal tuberculosis with a spontaneous cure have been published in Norway, but the "cure" is usually at the expense of the functional capacity of the kidney. In two such cases, at necropsy or operation, the kidney felt as if made of cement.

131. **Acute Paralytic Occlusion of the Duodenum.**—Høyer applies this term to what others call acute arteriomesenteric occlusion, duodenojejunal ileus or acute gastroduodenal atony. The acute dilatation of the stomach is usually the most striking feature of the cases, and lavage of the stomach, with change to the prone position often bring relief and cure. In an otherwise typical case described there was no dilatation of the stomach, and von Haberer has published a similar case. The acute dilatation of the stomach may occur from some mechanical hindrance or from paralysis of the stomach or both. The mechanical hindrance may be from spasm of the pylorus from an impacted piece of meat or a polyp or a kinking of the pylorus or upper duodenum or from pressure from a tampon, as after a gallstone operation. When the mechanical hindrance is lower down, in the lower duodenum or upper jejunum, the course is less acute; the vomit contains bile, but no fecal matter, the peristalsis of the stomach is lively but the stomach may not become dilated, and in these cases no benefit is derived from change to the prone position. Gastroptosis seems to afford a predisposition. Høyer's experimental research on dogs has confirmed his clinical deductions that the explanation of the whole trouble is that the bowel becomes obstructed by paralysis and dilatation of the lower duodenum—irrespective of whether or not there is dilatation of the stomach. The occlusion is induced by some kinking or some fold or valve formation at the point where the loose duodenum joins the more solidly fastened and relatively narrow jejunum, that is, at the duodenojejunal flexure. Possibly also cases occur in which, without any actual mechanical occlusion, the lower third of the duodenum may become too weak to force its contents through the lumen of the flexure. Lavage of the stomach, the pelvis raised, and change of position are called for at once; the prone position or the knee-elbow, or merely lying on the right side may bring relief. If not, operative measures are indispensable. No food should be allowed by the mouth; fluids should be given by the rectum. When it is necessary to operate, jejunostomy with a drain introduced into the duodenum seems rational or, possibly better yet, expose the duodenum after dividing the gastrocolic ligament between two ligatures, and try to mobilize the flexure, making a small opening into the duodenum and inserting a drain. The cases on record in which gastrojejunostomy was done or merely the duodenum evacuated have given bad results, as also gastrostomy.

Ugeskrift for Læger, Copenhagen

Aug. 1, 1918, **80**, No. 31

132 *Test for Sugar. H. C. Hagedorn and B. N. Jensen.—p. 1217.

132. **Quantitative Determination of Minute Amounts of Sugar.**—Hagedorn and Jensen comment on some of the disadvantages of Bang's micromethod for determining the sugar content of blood; among others the extreme precision required in the boiling procedure, and the nondurability of the iodin solution. With potassium ferricyanid it is possible to obtain equally reliable findings without these drawbacks, as they describe in detail. The technic is based on the fact that a chemical once reduced does not become oxidized anew during the short time required for the test. Several tables are given showing the precision of the method. The technic is simple although five reagents are required.

THE RETROGRADE MOVEMENT OF URETERAL CALCULI

HERMAN L. KRETSCHMER, M.D.
Captain, M. R. C., U. S. Army; Urologist, Presbyterian Hospital; Genito-Urinary Surgeon, Alexian Brothers' Hospital
CHICAGO

The advent of the roentgen ray marks the beginning of the period which is rightly characterized as the period of accurate and intelligent treatment of ureteral calculi. The roentgen ray, while contributing so largely to the diagnosis and treatment of this condition, is also accompanied by certain sources of error, chief of which are: (1) failure to demonstrate a calculus when present; (2) a wrong interpretation of shadows found in the plate, and (3) failure to find at operation a calculus which was definitely demonstrated by the roentgen ray to be in a "given portion" of the ureter.

1. With improved technic, failure to demonstrate the presence of a stone when present now makes up a very small percentage of cases. This small percentage can be still further reduced by subsequent examinations with the roentgen ray, by a careful rereading of the plates, by intra-ureteral injections of colloidal silver salts, and by the use of wax-tipped catheters.

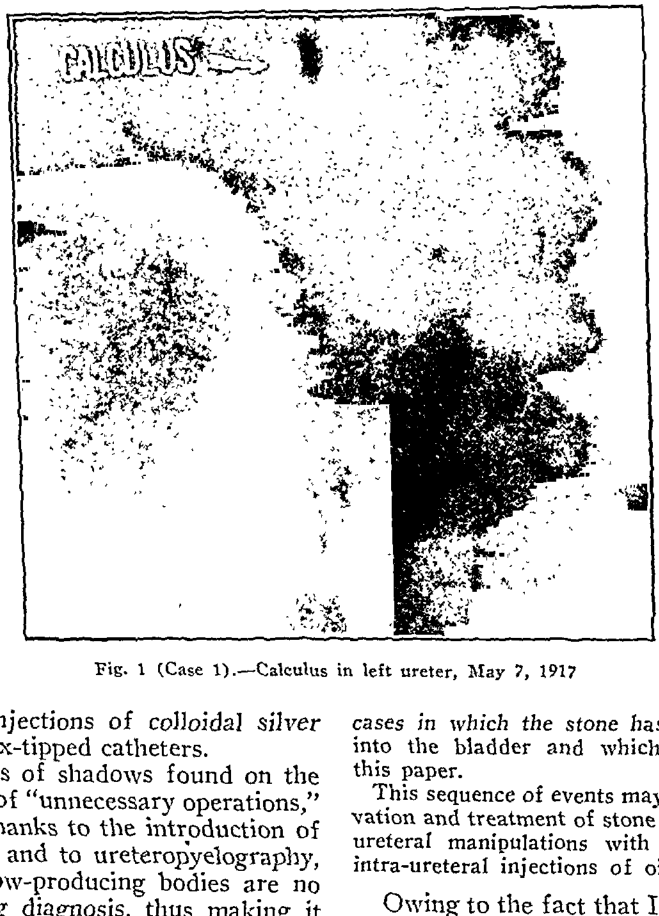

Fig. 1 (Case 1).—Calculus in left ureter, May 7, 1917

2. Wrong interpretations of shadows found on the plates have been the cause of "unnecessary operations," and still lead to them. Thanks to the introduction of the shadowgraph catheter and to ureteropyelography, these extra-ureteral shadow-producing bodies are no longer a source of wrong diagnosis, thus making it possible to avoid unnecessary operations. The nature and origin of these bodies have been described so many times that it is not necessary here to enter into a detailed discussion of them. There is still a very small percentage of cases in which the source of error consists in the passing of a shadowgraph catheter, localizing the stone or suspected stone shadow thereby, and yet finding no stone at operation. Another source of error consists in the fact that the shadow, while extra-ureteral, lies in the same plane as the shadowgraph catheter. To overcome this error, stereoscopic plates should be made in all doubtful cases.[1] Still another source of error will be considered under the next heading, on the failure to demonstrate at operation a calculus which was definitely demonstrated by roentgen ray in a given portion of the ureter.

3. There has been introduced into this topic another phase equally important as the ones just discussed, if not more important, because occasionally it results in an operation that fails to relieve the patient of the calculus. I refer to a condition which, for want of a better term, may be designated as the retrograde movement of ureteral calculi.

The circumstances are generally about as follows, in the order of their sequence:

The patient has symptoms and signs of stone in the ureter.

This is verified by the roentgen ray and the shadowgraph catheter.

The patient is operated on and no stone is found at the location in which a stone shadow was seen on the roentgenogram.

Further roentgenograms show that the stone has wandered back up the ureter or perhaps back into the kidney, excluding that group of cases in which the stone has wandered down the ureter or into the bladder and which are not to be considered in this paper.

This sequence of events may also occur following the observation and treatment of stone in the ureter by means of intra-ureteral manipulations with the ureteral catheter and the intra-ureteral injections of oil, glycerin, papaverin, etc.

Owing to the fact that I narrowly escaped this error, namely, of operating on the wrong part of the ureter, in one case, and because I saw the same phenomenon occur in a case under treatment without operation, and for the purpose of calling attention to this all-important fact, thereby possibly preventing others from falling into the same trap, I shall report two cases.

---

[1] Recently we have used a new procedure which consists of making a double exposure on a single plate. The technic for this procedure is fully described in: Kretschmer, H. L.: A New Method for the Localization of Ureteral Calculi, Surg., Gynec. and Obst., to be published.

REPORT OF CASES

Case 1.—*History.*—A man aged 50, referred to me by Dr. Clifford McCullough, entered the Presbyterian Hospital, May 7, 1917, complaining of pain in his left side. This pain was first noticed about 1 p. m., May 5, and was dull in the beginning and later colicky in type. It radiated along the course of the ureter and into the scrotum. By 6 p. m. he had a chill and his temperature began to rise. Alternating periods of chill, fever and perspiration continued for forty-eight hours, when he was taken to the hospital. During this time the output of urine was scanty.

Fourteen years before the patient had had a severe attack of ptomain poisoning. In 1906 he consulted Dr. Frank Billings. At that time no stone was found in the urinary tract and a diagnosis of pyelitis was made. Since then he has had varying forms of treatment, and was sent abroad for the cure of Bright's disease. In 1907 he had another severe attack, lasting six weeks.

The last attack of renal colic occurred four weeks before I saw him and lasted for twenty hours. During some of the attacks he had severe spells of hiccup, one of which lasted for four days.

Seven years ago the patient passed a small stone.

The patient denied all specific infection. His habits were moderate. He used alcohol and tobacco only occasionally, and his diet was rigidly meat-free for years.

Examination.—The patient was well nourished and of good color. He suffered considerable pain. The pupils were equal and reacted to light and accommodation. The neck, lungs and heart were negative. The liver was palpable on deep inspiration, and there was considerable tenderness over the region of the left kidney and ureter. The kidneys and spleen were not palpable. The genitalia were negative and the reflexes were normal.

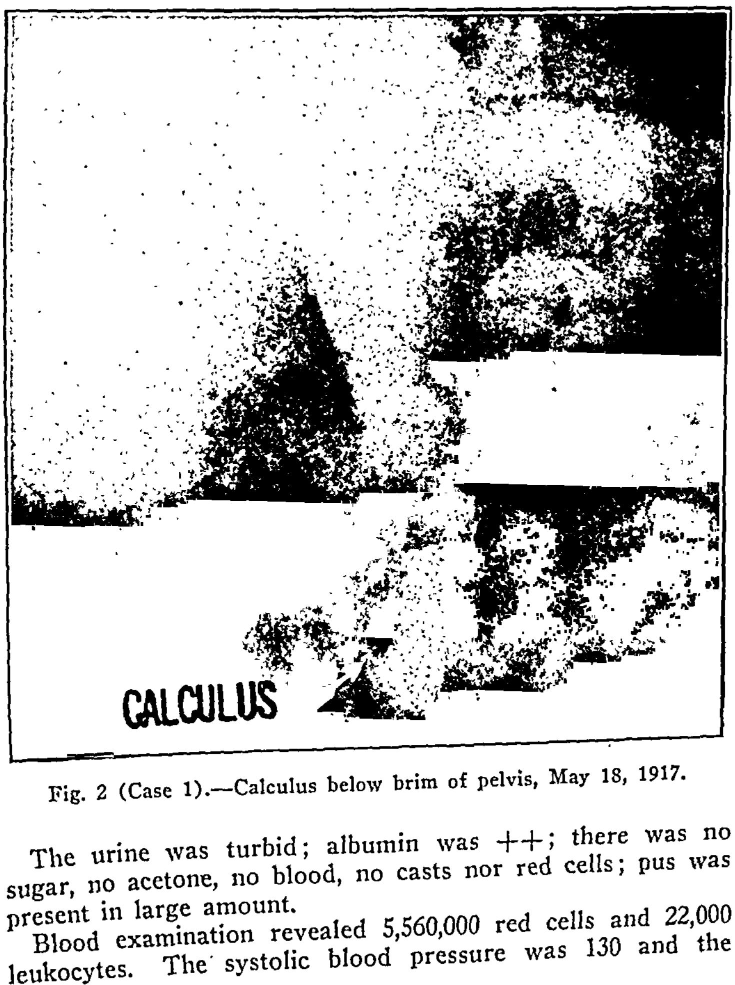

Fig. 2 (Case 1).—Calculus below brim of pelvis, May 18, 1917.

The urine was turbid; albumin was ++; there was no sugar, no acetone, no blood, no casts nor red cells; pus was present in large amount.

Blood examination revealed 5,560,000 red cells and 22,000 leukocytes. The systolic blood pressure was 130 and the diastolic 70.

Roentgenoscopy revealed a calculus in the left ureter at the level of the fourth lumbar vertebra (Fig. 1).

On cystoscopic examination the bladder was negative except for a slight amount of congestion around the internal urethral orifice. Both ureteral orifices were normal. Because of the large size of the stone, it was thought advisable to increase the size of the left ureteral orifice. Therefore, the left ureteral orifice was slit with the scissors, introduced through the operating cystoscope. A ureteral catheter was passed until an obstruction was met high up in the ureter, and 20 c.c. of sterile oil were injected.

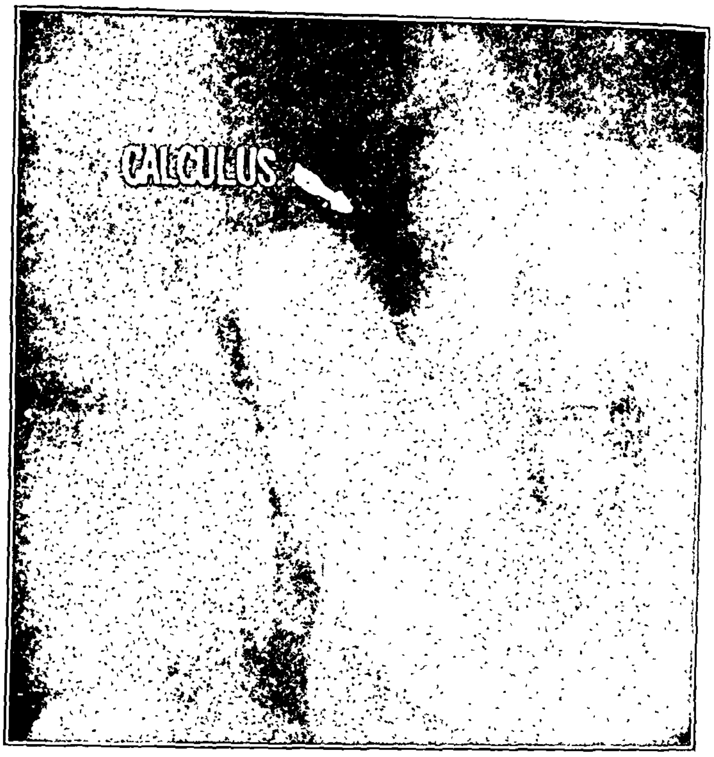

Fig. 3 (Case 1).—Calculus over edge of sacrum, May 27, 1917.

Treatment and Course.—Following the cystoscopy, the patient became very toxic and had a chill which lasted twenty minutes and a temperature of 103; he was somewhat irrational. This was followed by hiccup, which lasted five days.

At a phenolsulphonephthalein test, June 10, the appearance time was eight and one-half minutes; the output for the first hour was 18 per cent., and for the second hour, 20 per cent.

From May 19 to June 21, the patient received a total of four injections of sterile olive oil into the left ureter, the amounts varying from 15 to 25 c.c. During this time he also received four injections of a 2 per cent. solution of papaverin hydrochlorid.

The patient left the hospital, June 19, very much improved.

A series of roentgenograms, made at various dates from May 7, 1917, to Feb. 5, 1918, show that the calculus, during the intra-ureteral treatment, wandered from a position opposite the third lumbar vertebra down into the pelvis, so that it was seen lying along the margin of the sacrum (Fig. 4). Just before the patient left the hospital, another roentgenogram was made; this showed that the stone had wandered back up the ureter so that it lay opposite the transverse process of the fourth lumbar vertebra.

Two subsequent roentgenograms, one made Aug. 8, 1917, and one Feb. 5, 1918, showed the stone in approximately the same position as it was when the patient left the hospital.

From a review of this series of roentgenograms (Figs. 1, 2, 3, 4, 5, 6 and 7), it is evident that the stone wandered from the lumbar portion of the ureter into the pelvic portion and subsequently wandered back up into the lumbar portion of the ureter. These roentgenograms, however, did not show the lowest position which the stone attained, for at one of the ureteral catheterizations the catheter met an obstruction about 1 inch above the ureteral orifice.

Case 2.—*History.*—A physician, Dr. Z., aged 38, had an attack of renal colic fourteen years before, associated with pain in the penis and testicles, during which time he passed two small kidney stones. In the summer of 1914 he again noticed some blood in the urine. In 1915 he had a very severe hemorrhage, passing about a pint of port wine colored urine without any pain; he also passed a great many large clots. The hematuria has been more or less continuous ever since; at times the urine was clear for a few days. The last attack of hematuria occured a week before his admittance, Aug. 14, 1917. He also complained of pain in the left groin. This was so distinct that he could put his finger on the spot, and at times was so severe that he was obliged to take morphin. The only urinary symptom was that of pain, which was always present at the end of urination. The patient had a backache, which was dull in character and aggravated by standing.

Examination.—The general physical examination was completely negative.

Examination of the urine revealed an alkaline reaction, specific gravity 1.020, albumin +, blood +, and no sugar. Microscopic examination revealed pus cells and red blood cells.

A roentgenogram, made by Dr. H. E. Potter, disclosed the presence of a stone in the left ureter, near the junction of the ureter with the bladder (Fig. 8). The kidneys were negative.

Cystoscopic examination revealed the bladder and ureteral orifices normal.

Treatment and Course.—At ureteral catheterization the ureteral catheter met an obstruction 1 inch above the ureteral orifice. Because of the low lying position of the stone, as verified by roentgenoscopy and obstruction to the catheter, it was decided to slit the ureteral orifice with the operating scissors and to inject papaverin and oil into the ureter. In all, the patient received three injections of oil and papaverin without the position of the stone changing.

In view of the fact that the stone failed to respond to this treatment, and because of the subjective symptoms, which were enough to interfere with the patient's occupation, it was decided to operate. I had planned to perform a suprapubic cystotomy and remove the stone transvesically. Just before the patient was taken to the operating room, another roentgenogram showed the stone lying between the fourth and fifth lumbar vertebrae (Fig. 9).

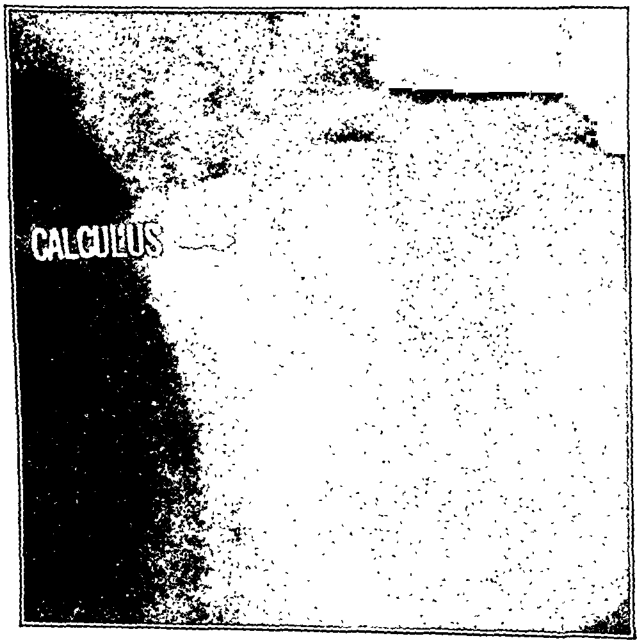

Fig. 4 (Case 1).—Calculus at edge of sacrum, June 1, 1917.

From these pictures, made Aug. 14 and Oct. 5, 1917, it is clear that the calculus wandered back up the ureter from a point just outside the bladder to a point in the lumbar portion of the ureter between the fourth and fifth lumbar vertebrae.

I removed the stone by an extraperitoneal ureterotomy. This precautionary measure of taking a roentgenogram just before the patient received the anesthetic prevented my carrying out the operation originally planned, namely, a suprapubic operation, which, had it been carried out, would not have been successful under the circumstances.

COMMENT

The question that most naturally arises from the experience of having two cases of retrograde movement of ureteral stone is, How is it possible for a stone to wander back up the ureter for a varying distance or even to wander back into the renal pelvis?

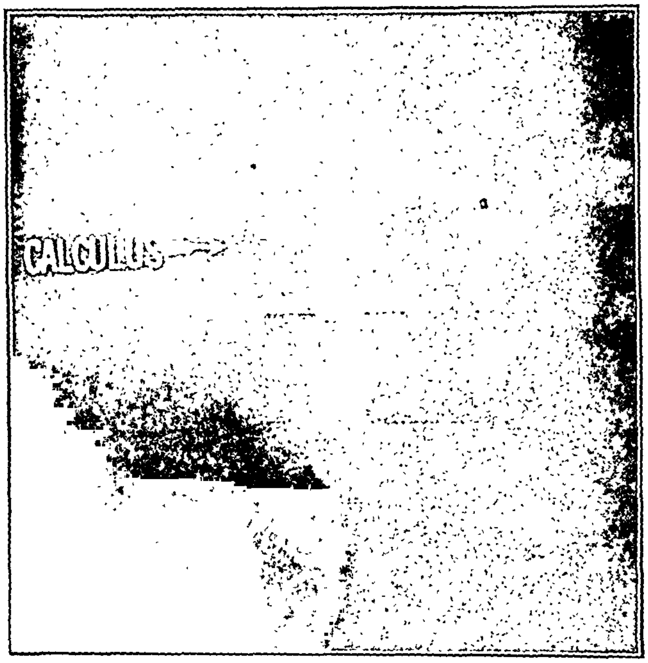

Fig. 5 (Case 1).—Calculus opposite fourth lumbar vertebra, June 19, 1917.

Two possibilities at once suggest themselves:

1. In the first group of cases the ureter is dilated, either as the result of the presence of the stone or of some other pathologic condition, as stricture, to such a degree as to permit the stone to fall about at will, so that when the patient is erect the stone will lie in the lowest part of the ureter, and when the patient is placed on his back or in the Trendelenburg position, the stone falls "up" the dilated ureter for a variable distance or may even be found in the kidney pelvis.

This explanation suffices in a certain number of cases and has been proved correct at the time of operation, when the ureter was found enormously dilated. Cases belonging in this category have been reported by various authors, and in this connection may be mentioned the cases reported by Legueu,[2] Escat,[3] Thomas,[4] Holland,[5] Jeanbrau,[6] Hunter[7] and Fowler.[8]

Owing to the scarcity of cases reported, it appeared to be desirable to collect as many instances as possible from the literature at hand and make brief abstracts. These are given at the end of the paper.

From some of the case reports it appears that the stones were located in dilated ureters and that because of the dilatation the stones were able to wander up and down the ureter at will. This conclusion is borne out by the fact that the stones were changed in location by changes in the position of the patients, and furthermore by the fact that at the time of operation the ureter was found to be dilated.

2. The second group of cases, namely, those in which no dilatation of the ureter was found at operation, will have to be explained on another basis—that the retrograde movement of the stone was the result of reversed peristalsis of the ureter.

Reversed peristalsis occurs in other hollow viscera, such as the intestine, and it seems reasonable to assume that this phenomenon is also possible in the ureter, although many authors question this.

Evidence tending to substantiate this view has been brought forth both clinically and experimentally. That fluid can travel from the bladder up into the kidney has been demonstrated roentgenographically by various observers in cases in which there was no disease of the genito-urinary tract. In a study of a large number of cystographs made in normal cases, I[9] have shown that solutions of thorium, collargol or cargentos, placed in the bladder, can find their way into the renal pelvis. In cases in which there is disease of the ureteral orifice (tuberculosis) that would interfere with the normal closure, this would of course occur, but these cases do not come under consideration here.

The question may therefore be raised that if it is possible to have fluid propelled up into the pelvis of the kidney from the bladder, is it not possible to have a stone transported upward by reversed peristalsis?

Besides this above-mentioned proof of the possibility of fluid going up into the kidney from the bladder, there can also be brought forth experimental work in which the phenomenon has been demonstrated in laboratory animals. In view of the fact that a regurgitation is possible, it naturally brings up the question of the mechanism by which this regurgitation takes place.

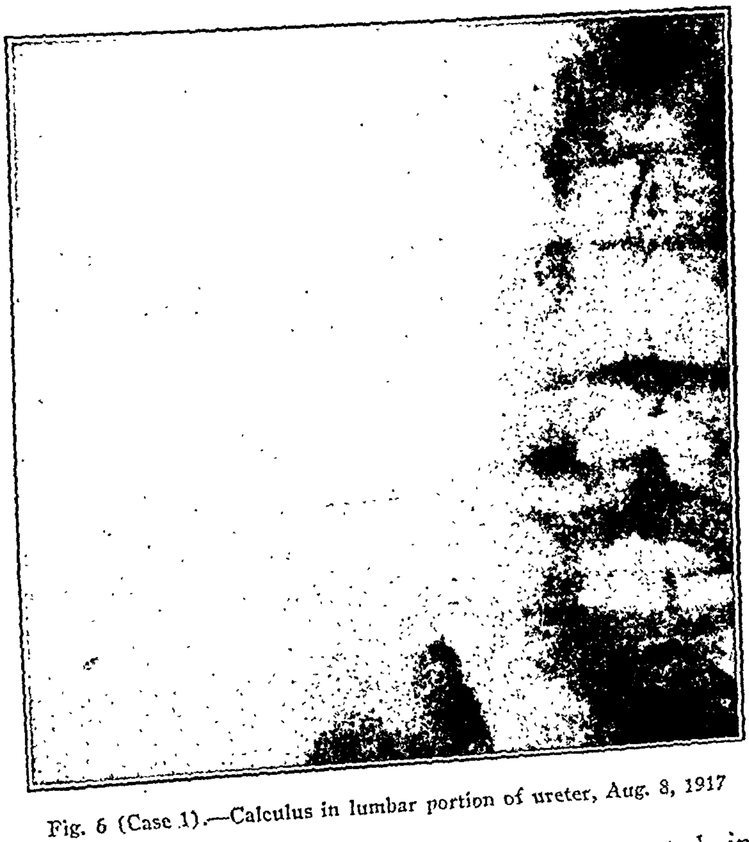

Fig. 6 (Case 1).—Calculus in lumbar portion of ureter, Aug. 8, 1917

The following possibilities may be mentioned:

First, that the ureter remains passive; that at the time the ureterovesical valve or sphincter opens to permit the escape of urine, the fluid in the bladder finds its way up the ureter.

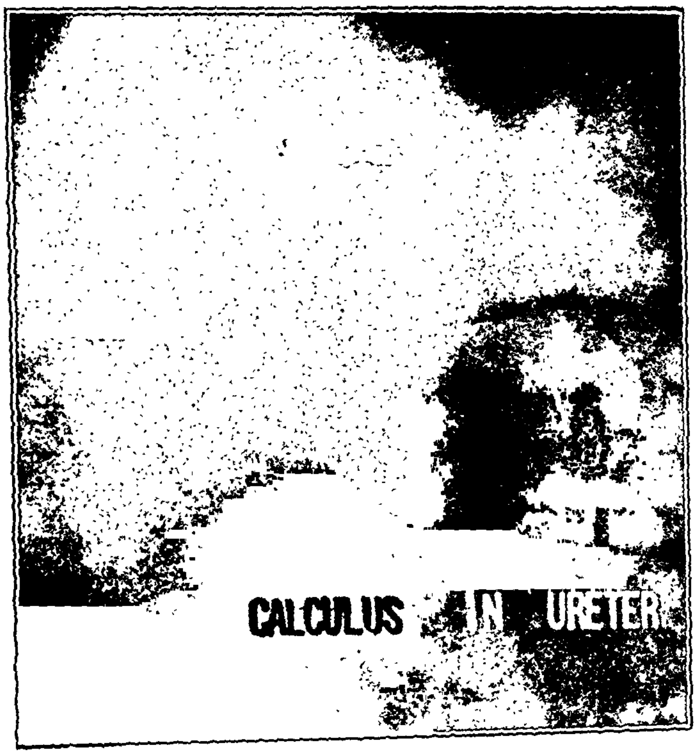

Fig. 7 (Case 1).—Calculus in practically the same position, Feb. 5, 1918.

Second, that the fluid is propagated upward by a reversed peristalsis, and if fluid may be propagated upward by a reversed peristaltic action, why cannot the same reversed peristaltic action be responsible for the retrograde movement of at least some of the ureteral calculi?

Reversed peristalsis of the ureter was demonstrated experimentally by Semblinoff in 1883; he was probably the first to demonstrate a back flow of urine from the bladder to the kidney. He demonstrated the following facts:

1. That a back flow of urine from the bladder into the ureters and kidneys may take place under normal anatomic conditions.
2. That this may be caused by a series of combined movements of the bladder and ureter.
3. That this explains the kidney changes in cases of pyelonephritis of vesical origin.

Semblinoff,[10] by the mechanical irritation of a dog's bladder distended to a certain degree, produced antiperistaltic movements of the ureter, so that Berlin blue solution was driven back through the ureters from the bladder to the kidney pelvis.

In 1893, Lewin and Goldschmidt[11] took up the question of reversed peristalsis and regurgitation of fluid up the ureter. Reviewing their experiments, they found that there was a reflex of bladder contents into the ureter and kidney pelvis. They likewise observed both peristaltic and antiperistaltic movements.

According to Alksne,[12] every part of the ureter is irritable and reacts to mechanical and electrical stim-

ulation with contractions. The contractions produced by stimulating any given segment of the ureter are transmitted in both directions, toward the kidney as well as toward the bladder. On irritating the bladder end of the ureter, pronounced antiperistaltic waves are produced.

From the above-mentioned facts it must be conceded that reflux of fluid up the ureter is possible and that reversed peristalsis has been amply demonstrated in the laboratory. In the face of this clinical and laboratory evidence, it would appear logical to assume that the calculi in a certain percentage of cases change their positions because of the presence of a dilated ureter, and that in a certain number of them the retrograde movement of the stone is due to reversed peristalsis.

CASES REPORTED IN THE LITERATURE

Legueu[7].—In a patient, aged 30, who had recurrent attacks of kidney colic, a roentgenogram disclosed two calculi in the left kidney that were movable and could be displaced. In a series of ten roentgenograms the calculi were never found in the same location; sometimes they were in the kidney and sometimes in various places along the ureter. At operation the kidney was dilated and the pelvis and ureter more so.

Escat.[3]—A man, aged 36, had attacks of pain, vomiting and difficult urination. Cystoscopy revealed a calculus protruding from the ureteral orifice. A roentgenogram revealed a calculus in the prevesical ureter. Suprapubic cystotomy was performed; and the stone, which could be seen with the cystoscope, could not be seen. It was felt 8 cm. from the ureteral meatus. The ureteral orific was slit, and the patient subsequently passed the stone.

Thomson-Walker.[13]—In a patient on whom operation was performed, a round calculus the size of a marble traveled from the lower part of the pelvic ureter into the lumbar ureter, when the patient was placed in the Trendelenburg position.

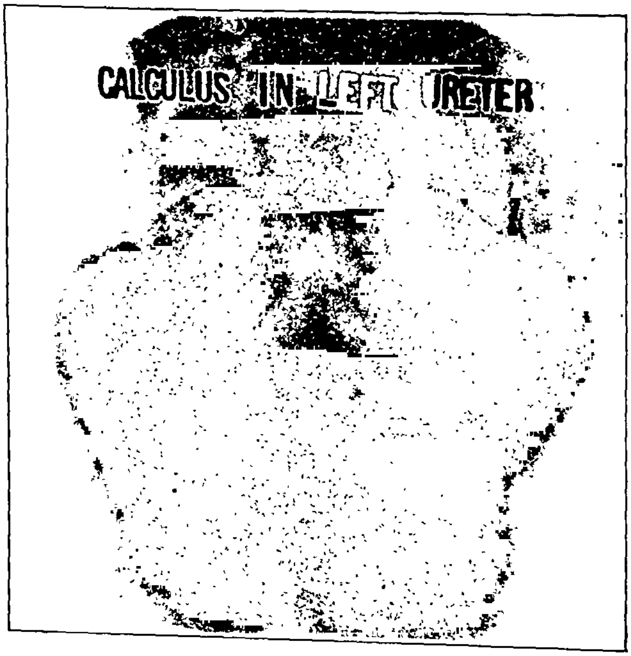

Fig. 8 (Case 2).—Calculus in pelvic portion of ureter, Aug. 14, 1917, about seven weeks before operation.

Thomas.[4]—A man, aged 23, gave a history of stoppage of urine and hematuria. Four sets of roentgenograms were taken on four different days with these findings: November 13, one stone in kidney, two in pelvic ureter and two (?) in bladder; November 22, one in kidney, one in pelvic ureter and three (?) in bladder; November 25, one in kidney, one in pelvic ureter and three in bladder; November 27, four in pelvic ureter and one in bladder. At operation one stone was found in the bladder, and four were removed from the dilated portion of the ureter. Thomas concludes that the dilatation of the ureter permitted the stones to move up and down according to the position of the patient.

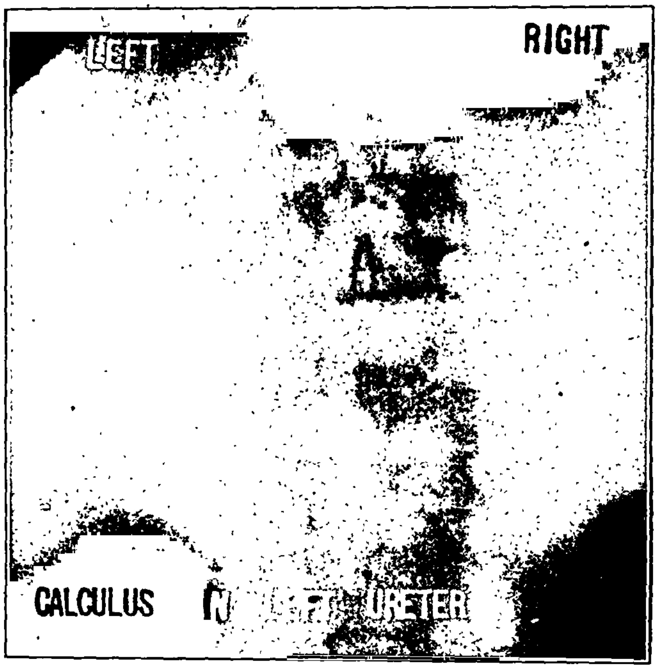

Fig. 9 (Case 2).—Calculus in lumbar ureter, Oct. 5, 1917, just before patient was anesthetized.

Codman.[14]—The ureter was greatly dilated, associated with an intravesical cyst of the ureter. Codman believes that the high position of the stones found at operation was due to the Trendelenburg position of the patient.

Hunter.[7]—A woman was operated on twice for stone in the lower ureter and no stone was found, although at the operation the ureter was found dilated and inflamed. Later the stone was found in the pelvis of the kidney. When the patient was up the stone would descend to the lower end of the ureter, but when she remained in bed it worked back up into the kidney.

Fowler.[8]—In a case of stone in the ureter Fowler had the unpleasant experience of operating and failing to find the stone. He finally succeeded in removing it from the kidney.

Holland.[5]—A woman, aged 45, had had attacks of pain in the right loin with backache and hematuria for six years. Roentgenoscopy revealed a small calculus in the right kidney and also a very large shadow in the pelvis, more than an inch long. The small kidney stone was removed and the ureter probed, but no other stone was found. On roentgenoscopy the next day, the large pelvic shadow had disappeared. Two and a half months later the patient returned with the same complaint, and a roentgenogram revealed the same shadow in the right kidney. Another roentgenogram, made a few days later, just before the patient was to be operated on, revealed no shadow in the kidney pelvis, but a stone was seen in the lower end of the ureter. The ureter was opened and the stone removed. The ureter was dilated and this large stone could apparently move at will up and down its whole length.

ISOLATED DISEASE OF THE SCAPHOID *

CHARLES R. McCLURE, M.D.
Lecturer on Orthopedic Surgery, University of Oregon Medical School; Orthopedic Surgeon to Multnomah County Hospital
PORTLAND, ORE.

A pathologic condition limited to the scaphoid bone of the foot is rarely observed. First described by Köhler in 1908, it has since been known as "isolated disease of the scaphoid," or "Köhler's disease." Including the three cases described by Köhler, thirteen cases of this condition have been reported in the literature. Having had the opportunity of observing such a case recently, I have found it worth while to report it, incidentally directing attention to certain distinguishing features concerning its pathologic history.

REPORT OF CASE

A boy, aged 7 years, was brought to see me, Nov. 6, 1917. Lameness was the chief complaint. The family history was negative as to tuberculosis and syphilis. Both parents are living and well. The home surroundings, the rural environment of a prosperous farmer, had been ideal. The child had never had any illnesses, except measles and infected ears the preceding two winters, his health having been apparently perfect.

About two weeks before he came to see me, it had been noticed that he was limping and lame in his right foot. There had been no previous injury, except about six weeks before the onset of his symptoms, when a board had fallen across the dorsum of his foot. The lameness had persisted. Pain had seldom been complained of, and never when he was off his feet. There had been no night cries. A slight swelling had been noticed over the inner side of the dorsum of his foot.

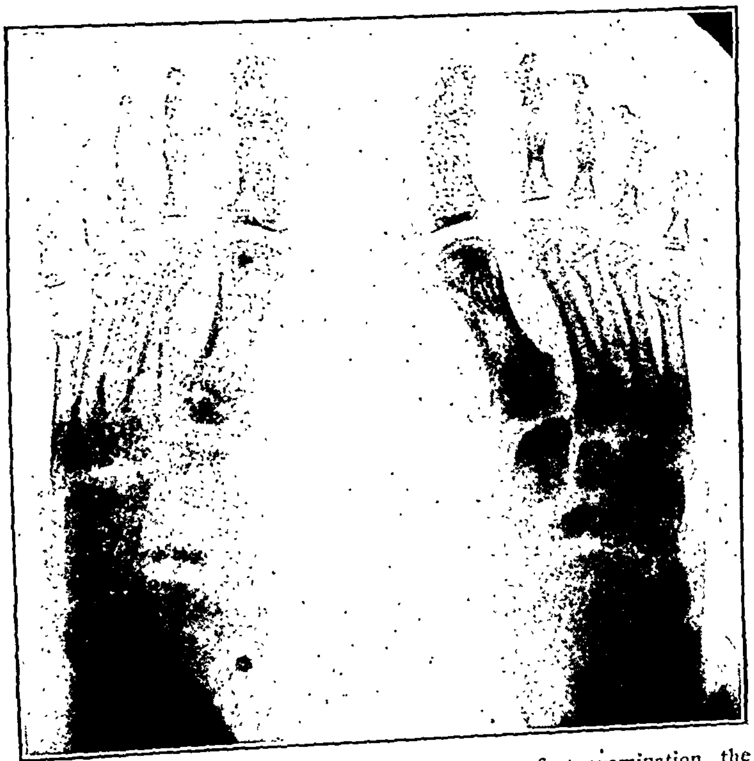

Fig. 1.—Roentgenogram of both feet taken at first examination, the right or diseased foot being shown at the left.

The physical examination revealed a well nourished, healthy looking boy. The general examination was negative. He walked with distinct lameness of the right foot. The ankle joint function was normal. Locally, there was a slight swelling over the inner side of the dorsum, also a slight tenderness, but no discoloration. When he stood and bore weight, there was marked pronation and bulging of the inner side of the foot.

The boy presented very notched teeth, but the Wassermann reaction was negative, likewise the von Pirquet reaction.

Roentgen-ray examination disclosed a typical appearance of the scaphoid. Lantern slides will demonstrate them better than I can describe them. Briefly, the shadow of the scaphoid was smaller than normal and irregular in outline, and the cortex and spongy portion showing no distinction (Figs. 1 and 2).

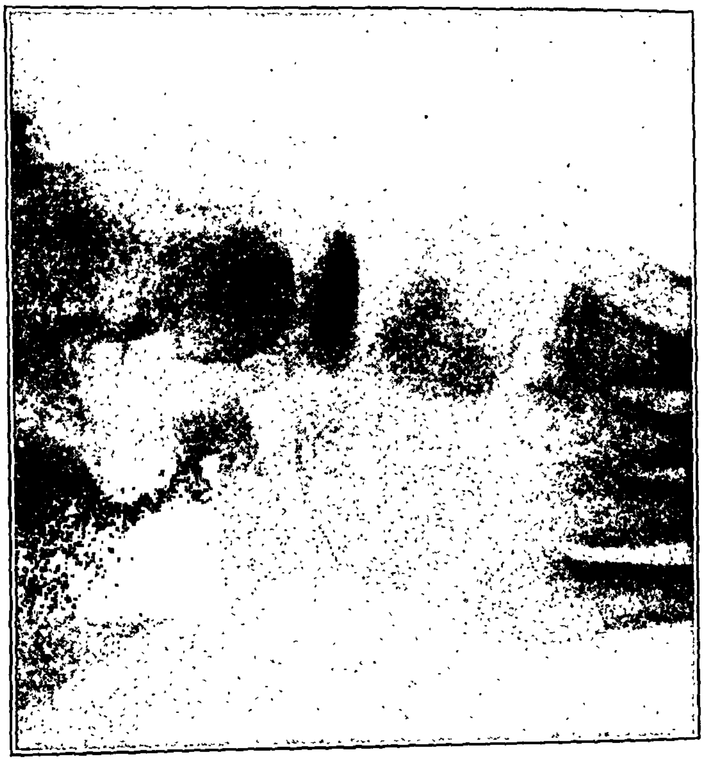

Fig. 2.—Right foot at first examination.

The diagnosis was Köhler's disease of the scaphoid. Treatment consisted of immobilization in plaster-of-Paris and crutches.

Two months later, the boy was brought to see me again and the plaster was removed. All swelling and tenderness had disappeared and he was in his usual good physical condition. Another roentgenogram showed much improvement, as seen in the increased size and filling out of the irregular bone (Fig. 3). The density was also better. Another plaster dressing was applied and the patient was sent home.

Three months later, or five months after the first examination, he again returned to Portland. The plaster was removed and the foot looked normal in every way. Another roentgenogram disclosed an almost perfect scaphoid, and he was considered practically cured (Fig. 4). Living several hundred miles away, he was sent home with another plaster dressing to be worn for a month, with instructions to follow it with adhesive plaster strapping and to wear a supportive shoe while gradually resuming use of the foot. Late reports are that the boy seems perfectly well.

ETIOLOGY

There is nothing new to be offered as explanatory of the etiology or nature of the affection. Numerous theories as to its etiology have been advanced, but the situation is still doubtful. With Pfahler,[1] all authors agree that it is not tuberculous. Fassett[2] inclines to the theory that it is a mild tuberculous focus, the wall of cicatrization having been broken down by some trauma. My own case does not impress me as tuberculous, as the amount of bone involvement pres-

---

* Read before the Section on Orthopedic Surgery at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[2] Fassett, F. J.: Isolated Disease of the Scaphoid, The Journal A. M. A., April 11, 1914, p. 1155.

ent within two weeks of the onset of symptoms and its rapid disappearance under treatment do not harmonize with the history of known tuberculous bone disease. The recovery has been too prompt and too complete to be consistent with tuberculosis.

That syphilis was not a factor in my case, in spite of the negative history and Wassermann reaction, is shown by the fact that recovery took place without any antispecific treatment.

Trauma has been considered a factor. While my case gives a history of a board falling across the foot six weeks before the onset of any symptoms, the circumstance seems almost too inconsequential to be a factor of much importance. Still Pfahler considers the condition as an osteitis, probably of traumatic or rheumatic origin, which interferes with the development of the bone. That it is inflammatory, almost all authors agree, but as to the nature of the inflammation, we are still at sea. Hetzel,[3] in his valuable paper of a year ago, notes the similarity of the condition and osteochondritis juvenalis of the hip, both occurring in the epiphysis at the height of ossification.

Delayed ossification has been suggested, but if one compares the roentgenograms of both feet (Fig. 1) in my case, it would be hard to explain why one foot lagged so far behind the other, except on account of trauma, which in my case would seem hardly sufficient.

The diagnosis is the important feature; for when once recognized, the prognosis is absolutely good, both as to function and cure, under rest and support in a comparatively brief period of time. Before this section, it is unnecessary to emphasize the importance of routine roentgen-ray examinations. But their importance should be more generally recognized. How often children are presented to us with weak feet or flatfoot! As they are at times associated with moderate swelling and tenderness, pronation on standing, and limping, especially if unilateral, we should be on our guard and make the roentgenogram a part of our examination. At times we all see tuberculous ankles that have been treated as flatfoot. Likewise these affections, similar to the one under discussion, should not be considered as a broken arch or flatfoot and so treated. The discovery of one such case all the more thoroughly justifies routine roentgen-ray examination in all foot cases of doubtful history.

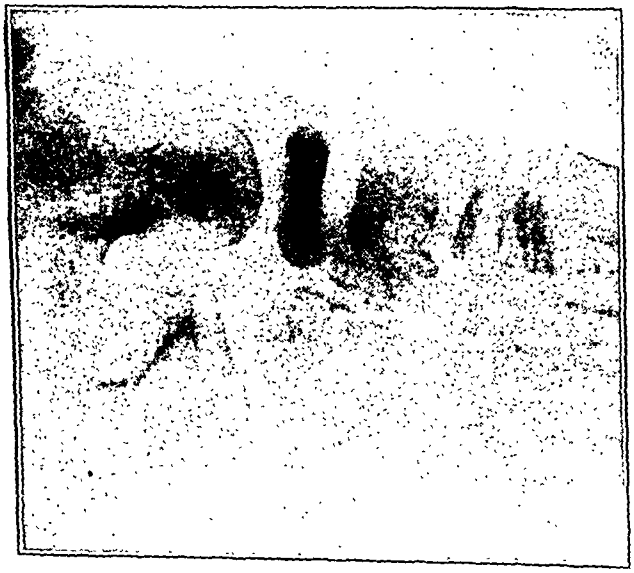

Fig. 3.—Right foot two months later.

ABSTRACT OF DISCUSSION

Dr. Willis C. Campbell, Memphis, Tenn.: I have had two cases of this condition within the past year, and two others in previous years. Trauma did not seem to be the cause in any of the cases I have seen. In one of my cases the Wassermann was 2 +, and it was interesting that the grandmother of this child was under my care for syphilitic periostitis, with a 3 + Wassermann. The grandmother responded to treatment. The child has been on antisyphilitic treatment, and I am doubtful whether the improvement in the condition has anything to do with the treatment. The roentgen-ray findings are quite characteristic, as Dr. McClure described. For instance, in the scaphoid the edge is somewhat irregular in appearance, and on the side view it looks like a flattened coin. I have not used plaster or any other form of fixation in these cases. I have used a simple steel arch support, which has been quite sufficient.

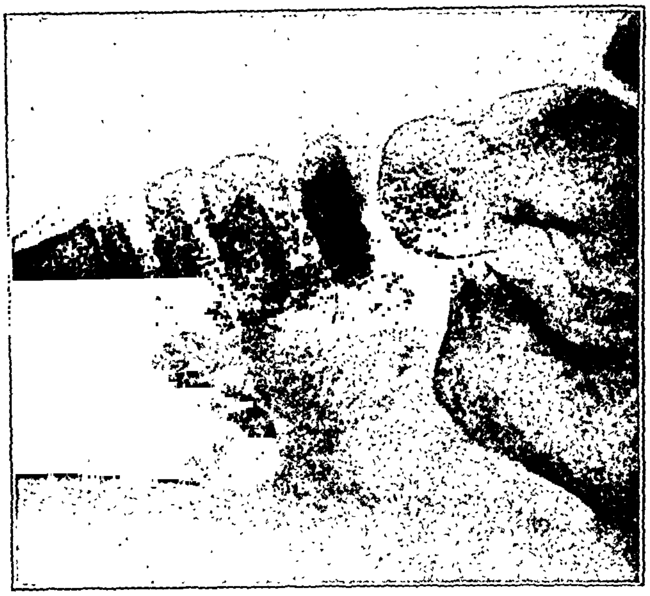

Fig. 4.—Right foot five months after first examination.

Dr. S. C. Baldwin, Salt Lake City: I should like to know what treatment the doctor used, if any, besides the plaster cast.

Dr. Charles R. McClure, Portland, Ore.: The treatment consisted exclusively of immobilization in plaster of Paris and keeping the weight off the foot.

Cooperation in Treatment.—The late S. Weir Mitchell was a marvel of proficiency in curing patients. Those associated with him professionally usually endeavored to appropriate and apply his methods. To those of his assistants like myself, having experience with other neurological clinicians, illuminating contrasts are afforded. In my opinion the chief instrumentality of his amazing successes was his prompt and cordial cooperation with experts in correlated lines, himself not attempting to do it all. The distinguishing characteristic of Dr. Mitchell was his radiant energy and his clear-sighted recognition of the value of joint action. He so stimulated the zeal of his adjutants as to get the best out of them not only in diagnosis but in treatment. Thus an efficient coalition was constantly at work. He uniformly said and did the judicious thing to create and maintain team work. In leadership he was wisdom personified in plan, in strategy, in shifting the point of approach, in creating useful surprises, in persistent effort, thus achieving the most economic and permanent results.—J. M. Taylor, *Pennsylvania Medical Journal*, September, 1918.

FRACTURE OF THE SPINAL COLUMN WITH AND WITHOUT CORD INJURY

NORMAN SHARPE, M.D.
NEW YORK

When the subject of fracture of the spinal column is under consideration, we think of it in terms of cord symptoms—impairment of motility and sensation, or paralysis with disturbance of sphincteric control. This is natural, for in by far the greater number of fractures of the spine, the cord or its roots are involved, and the bony fracture itself is a minor hurt compared to the possible result if the cord also is injured.

There are, however, a large number of spinal fractures (Pearce Bailey estimates this to be one third of all cases) in which the cord and its roots escape damage. Unless careful examination is made, these cases are apt to be diagnosed as sprain or contusion. In a recent article I[1] reported such a case, a fracture dislocation of the second cervical vertebra without damage to the cord. Since then I have seen five other cases, in some of which the bone injuries were such that it is difficult to understand how the cord escaped involvement.

In four of these cases the fracture occurred in the vertebral bodies, in two of them the bodies being almost completely crushed. Yet these patients were able to stand and move after the accident. As we know that many of the posterior arches or laminae can be removed without materially weakening the spine, and, as we have just seen, crushing of a vertebral body does not render one unable to stand erect, it is apparent that the main support or strength of the spinal column lies in the articulations on the transverse processes. And it is rare in fracture by indirect force to have the cord injured (except by hemorrhage) unless there is rupture of these articulations. The converse is also true, that the most severe injuries of the cord are seen when these articulations are ruptured, the familiar unilateral or bilateral fracture-dislocation of one or more vertebrae.

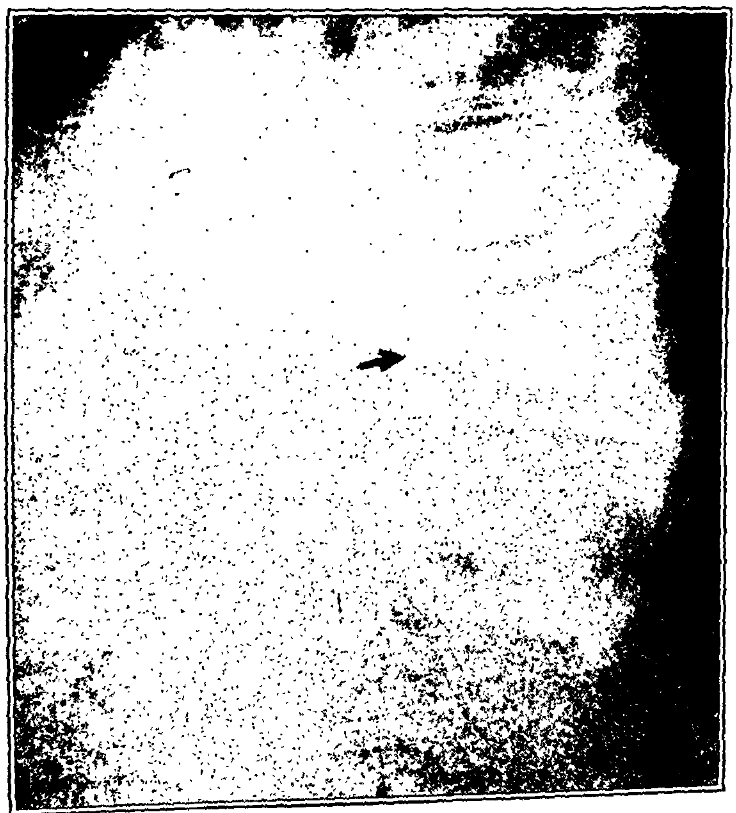

Fig. 1 (Case 1).—Fracture of the body of the eleventh dorsal vertebra.

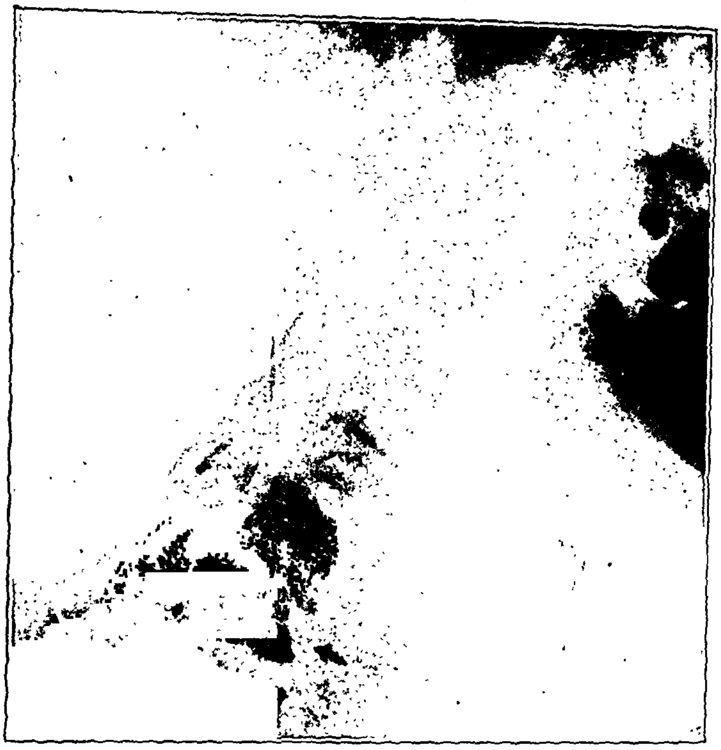

Fig. 2 (Case 2).—Fracture-dislocation of the sixth cervical vertebra.

In fracture-dislocation, the displaced vertebra may remain displaced, or spring back partially or completely into its normal position, leaving as the only signs of its dislocation the signs of cord injury. These signs may vary from partial paralysis to complete abolition of all function below the lesion, giving rise to the suspicion that the cord has been completely crushed at the point of injury. But, as was pointed out in a former article,[1] complete abolition of function below the lesion in a spinal fracture does not prove that the cord is completely crushed or severed, or even that it is damaged beyond repair. This has been shown time and again at operation, and also in the after-results in unoperated cases.

In a case recently seen by me, one and a half years after the accident, there had been a fracture of the fifth and sixth cervical vertebrae, with complete loss of function below the lesion. On the ground that this showed complete destruction of the cord, operation was withheld. Three months after the accident there was slight return of power in the right leg and partial return of sensation over the body below the lesion. At this time operation was again withheld, on the ground that the improvement was too slight to make it worth while to operate, and, on the other hand, that as the condition was improving it would be better to wait and see how much it would improve. Eighteen months after the accident the patient reported that improvement had ceased at the end of one year. He could weakly raise the arms, but could not bring them down, and could weakly extend and flex the right foot and leg. There was hypesthesia to all forms of sensation below the lesion, with complete loss of sphincteric control. He could not stand or even sit. Laminectomy was done and the laminae and pedicles of the fifth and sixth cervical vertebrae were found fractured and jammed about the cord, severely compressing it. The dura had not been torn, and the cord, though pale, was of normal appearance otherwise. Following operation there has been gradual return of power, so that now, six months after operation, there is fair strength in the arms, especially in the right, and the patient is able to walk with crutches. Hypesthesia has been replaced by areas of hyperesthesia and paresthesia. He is still improving.

---

[1] Sharpe, Norman: Am. Jour. Med. Sc., 1916, **152**, 865.

Though helped by late operation, how much more benefit would this patient have received by an early laminectomy. The only reliable sign that proves a complete crush of the cord, and the only contraindication to early operation, is a bony deformity so great as to show complete obliteration of the spinal canal. By the term "early operation" is meant a laminectomy after the patient has rallied from the initial shock of the injury. Naturally if the injury has been so severe, or if the patient's vitality is such, that he cannot rally from the condition of shock, any operation at this time will hasten death. A safe general rule to follow is not to operate while the pulse is above 110.

In many fractures of the spinal column without cord signs, the fracture has been entirely overlooked. In the case of a woman previously reported who fell on a stairway striking the back on a step, there were no signs of nerve involvement, and a fracture was not suspected. Months after the accident and when all pain had long since disappeared, cord symptoms appeared and gradually increased. Only when they became marked was attention directed to the old accident, and roentgenoscopy disclosed marked callus formation at the site of the injury, the twelfth dorsal and first lumbar vertebrae.

In the absence of cord symptoms and no marked protrusion or "knuckle" of the spine, the diagnosis is apt to be "simple sprain or contusion." Thus in Case 3, in which there was a marked crushing of the body of the twelfth dorsal vertebra, at the hospital to which the patient was first taken he was told that the injury was simply a contusion, and no roentgenogram was taken.

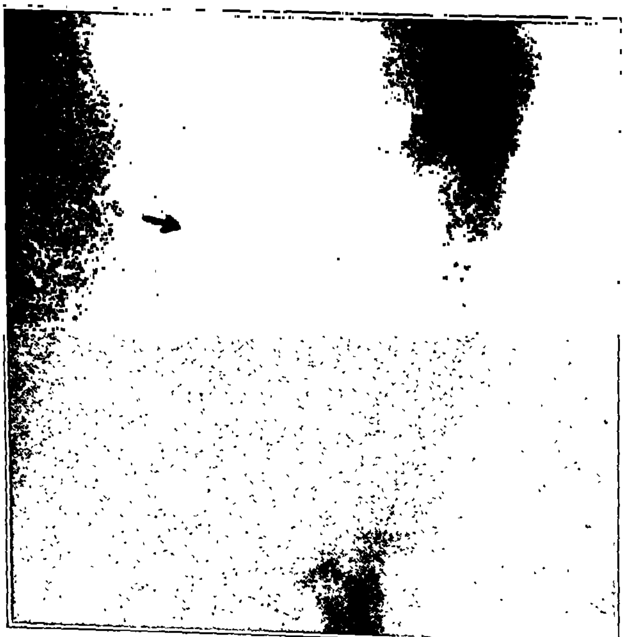

Fig. 3 (Case 3).—Crushing of the first lumbar vertebral body.

If other injuries are present, the spinal fracture without cord involvement is apt to be overlooked. In Case 4, in which severe burns of the arms and shoulders were sustained in addition to the injury of the back, the burns were treated as the principal lesion, and in the absence of cord symptoms no attention was given to the spine, though the patient complained of pain in the lumbar region. Three weeks later, when the burns were nearly healed, the persistence of the pains directed attention to the spine, and examination revealed alteration in the normal spinal curve in the dorsal lumbar region. Roentgenoscopy disclosed a marked crushing of the body of the twelfth dorsal vertebra.

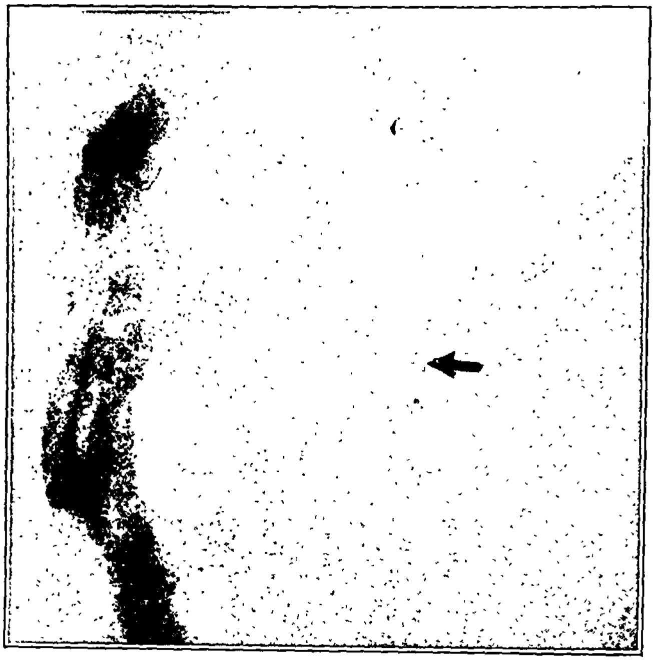

Fig. 4 (Case 4.—Crushing of the twelfth dorsal vertebral body.

These cases indicate the necessity of careful examination, both clinical and by the roentgen ray, of all cases of suspected injury to the spine. Although in neither of these cases did the failure to recognize a spinal fracture result seriously, it is readily conceivable that in a patient able to move about in bed with the fracture not immobilized, sudden twisting or turning movements by the patient or his attendants might easily convert a fracture without cord signs into a fracture with marked and serious cord involvement. Also failure to recognize a fracture and no attempt made to restore the normal spinal curve may result in weakening of the spinal column and more or less permanent disability, with perhaps appearance later of cord symptoms, due to new bone formation. This is especially true when the fracture occurs in the vertebral bodies.

The treatment of fractures of the spinal column without cord symptoms is immobilization. In fractures of the cervical vertebrae, immobilization is best secured by a plaster collar. If the fracture is high in the cervical region, an extension should be made from the collar about the forehead. If the fracture lies in the lower cervical region, an extension should also include the upper chunk. After from six to ten weeks, when all pain and tenderness have disappeared, the plaster may be followed by a stiff leather collar, which gives support but is more comfortable and allows greater freedom of movement. If the fracture lies in the laminae of the dorsal or lumbar vertebrae, a molded splint of plaster on each side of the spinal column and connected by transverse bands above and below the lesion will be found a satisfactory way of immobilizing the fracture and preserving the normal outline of the spinous processes. Fracture of the vertebral body is best treated by overextension on a Bradford frame, which is much more comfortable and efficacious than a plaster jacket.

REPORT OF CASES

The following cases, some of which were seen with Dr. William Sharpe, are examples of extensive fractures of the spine following severe injuries, without cord signs:

Case 1.—A. M., man, aged 22, while employed as a bell boy in September, 1915, fell through the dome of a skylight, a distance of 18 feet, striking the floor on his head and shoulders. Unconscious and severely contused, he was taken to a hospital where a *diagnosis* was made of fractured skull; this was changed a few days later to cerebral contusion. The patient was unconscious for three days, and stuporous and dazed for two weeks. There were no signs of cord involvement present at any time. No operation was done, and he was discharged from the hospital "improved," but complaining of headache and pain in his back. When seen, two months later, his cerebral condition had almost entirely cleared up except for occasional dull headache. His chief complaint was pain and weakness in the back aggravated by standing or walking. This pain was severe enough to prevent his returning to work. Examination disclosed a projection backward of the spinous process of the eleventh dorsal vertebra and alteration of the normal spinal curve in this region. Roentgenoscopy revealed moderate crushing of the body of the eleventh dorsal vertebra and slight dislocation backward of this vertebra; the upper borders of the twelfth dorsal vertebral body were "lipped," and there was evidence of slight crushing of this vertebra also. The neurologic examination was negative. The tendon and skin reflexes were present and normal; there was no Babinski reflex, no ankle clonus, no sensory changes and no disturbance of the sphincters. A metal brace was applied, causing slight overextension of the spine at this point. When seen two years later, the patient was found to be normal except for some spinal rigidity at the dorsal lumbar junction and slight alteration of the normal spinal curve. From habit he was still wearing the brace, which he was advised to discard.

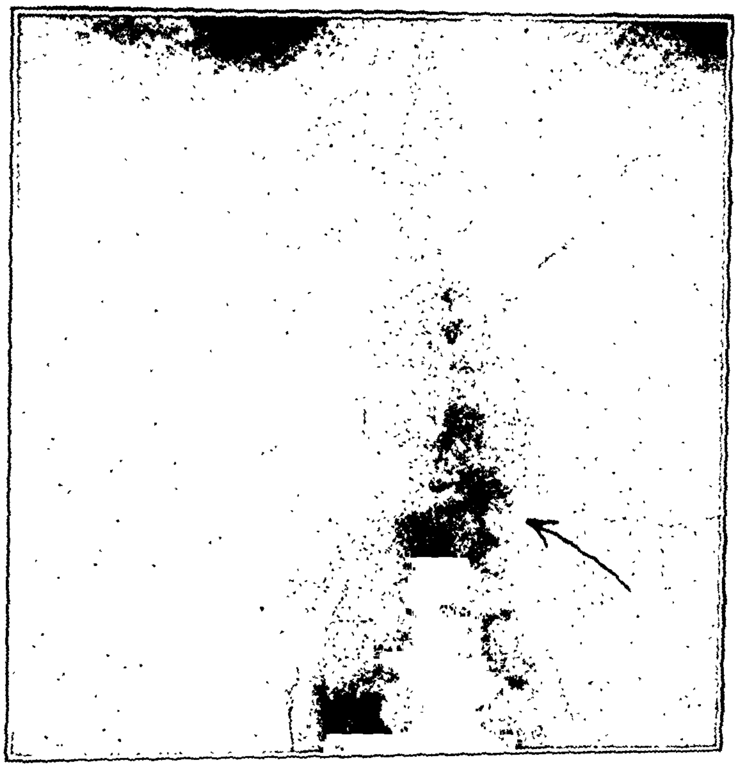

Fig. 5 (Case 5).—Fracture-dislocation of the fifth cervical vertebra.

Case 2.—R. H., a man, aged 20, while playing polo in October, 1915, was thrown from his horse, striking on his neck and shoulders. He was not unconscious, but complained of severe pain in the neck radiating to the back of the head. He was able to walk off the field. He remained in bed two days with severe pain in the neck. There was no radiation of pain in the arms and legs and no sphincteric disturbance. Two weeks later the lower tendon reflexes were found to be somewhat increased; there was no Babinski reflex; the abdominal reflexes were present and equal; there was no impairment of motility or of sensation in either the upper or the lower extremities. Roentgenoscopy (by Dr. Caldwell) revealed a fracture-dislocation of the sixth cervical vertebra with backward displacement of one-half inch. Naturally, in view of the fact that there were no signs of cord injury found, no operation was done, but the head and neck were placed in a plaster collar. The patient made an excellent recovery, so much so that in the following year he rowed on a 'varsity crew. There have been no complaints up to the present time.

Case 3.—S. B., a man, aged 30, in April, 1917, fell 40 feet from a window, first striking his back on a wooden railing 10 feet below the window, and then continuing to fall 30 feet, landing on a wooden floor on his left side. When he struck the railing he had severe pain, and says he "thought his back was broken." He was not unconscious and had no pain nor numbness in the legs. When lifted he was able to stand alone; he was taken to a hospital, where he was told that the injury to the back was a contusion. No roentgenogram was made. He had severe pain in the lumbar region and the left flank. There was no sphincter trouble, and he passed no blood. He was out of bed on the eleventh day, and left the hospital in two weeks. He was at home a week, in and out of bed, with severe pain in the back and some pain on the inner side of the left thigh. During this week he tried various "stunts to loosen up his back," getting down on the floor on his hands and knees and twisting about, kicking out with the feet, etc. This caused pain. Three weeks after the accident, examination revealed an alteration in the normal spinal curve at the dorsolumbar junction, a kyphosis, and protrusion of the spinous process of the first lumbar vertebra. Roentgenoscopy revealed marked crushing of the body of the first lumbar vertebra. There were no motor or sensory changes, and the reflexes were unaltered. There was some tenderness to pressure over the spine and marked tenderness in the left flank. The tenderness on the inner side of the left thigh disappeared the following week. The patient was placed on a Bradford frame with overextension of the spinal column for four weeks. When he left the hospital he was fitted with a steel brace, which he wore during the day for eight months. Examination nine months after the injury showed the spine strong and supple, with slight projection of the spinous process of the first lumbar vertebra. There were no root pains and no signs of motor or sensory involvement of the cord or roots.

Case 4.—C. P., a woman, aged 18, was trapped by fire on the fifth floor, in March, 1917. After clinging to the window-sill and being burned extensively on the arms and back, she fell and struck the middle of the back across an iron bar at the first story, and then fell to the ground. She was dazed but not unconscious, and after being lifted up could stand erect and move about. She was brought to the hospital in an ambulance. She complained of pain in the back at this time more than of the burns. There was no pain nor any numbness in the legs. The burns were treated and no attention was paid to the back. Thirty hours after the injury the temperature rose to 105 F. and fell shortly to 102; on the seventh day it was normal and continued so. The patient moved about in bed, but there was no weakness in the legs, though these movements caused pain. Three weeks later, because of the persistence of the pain, examination of the back was made and a protrusion found in the dorsolumbar region. Roentgenoscopy revealed marked crushing of the twelfth dorsal vertebra. Careful neurologic examination at this time showed no impairment of motility or sensation. The patient was placed on a Bradford frame in hyperextension, and the pain ceased in a day or two. After five weeks the patient was fitted with a rigid brace for the spine, which she wore for several months. Examination one year later showed her to be normal and able to work, and with no complaint.

Case 5.—H. B., a man, aged 47 years, while working as a ship rigger, in March, 1918, fell 35 feet and was unconscious for fifteen minutes. The right side of the head and face was badly cut and three ribs were broken, but his chief complaint was pain in the back of the neck. He was unable to turn his head in any direction on account of the pain in the neck. He was taken to a hospital, where he was told that his neck was sprained. He was twelve days in bed, being treated for the fractured ribs and other injuries, though his chief complaint was pain in the neck. No roentgenogram was taken at this time. Three weeks later, twenty-two days after the injury, the pain persisting, a roentgenogram was taken, which showed a dislocation backward of the fifth cervical vertebra with fracture of the body of the fourth cervical. Neurologic examination at this time was entirely negative. There was no impairment of motility or sensation and no alteration of the deep or superficial reflexes. The patient carried his head in a peculiar stiff manner, though he could move it without much discomfort. A plaster collar was applied and he is still under observation.

315 West Ninety-Seventh Street.

CANCER OF THE ORAL CAVITY, JAWS AND THROAT

TREATMENT BY ELECTROTHERMIC METHODS OR IN COMBINATION WITH SURGERY, THE ROENTGEN RAY AND RADIUM, WITH AN ANALYSIS OF TWO HUNDRED CASES SO TREATED *

WILLIAM L. CLARK, M.D.
PHILADELPHIA

Electrothermic methods are peculiarly adapted to the treatment of cancer within the mouth. Malignant tissue (including bone) occurring in any part of the oral cavity, comprising the lips, buccal surface, tongue, floor of the mouth, alveolus, hard palate, antrum, tonsils, pharynx, epiglottis, larynx and proximal end of the esophagus, may be destroyed with one electrothermic operation.

It is not necessary to split the cheek surgically to render a growth accessible to treatment, since the exposure secured by the use of a mouth gag, cheek retractors, traction on tongue by means of a suture or tongue forceps, or by the use of an endoscope is sufficient to permit the destruction of a growth. A tongue may be coagulated to the base and then excised without hemorrhage.

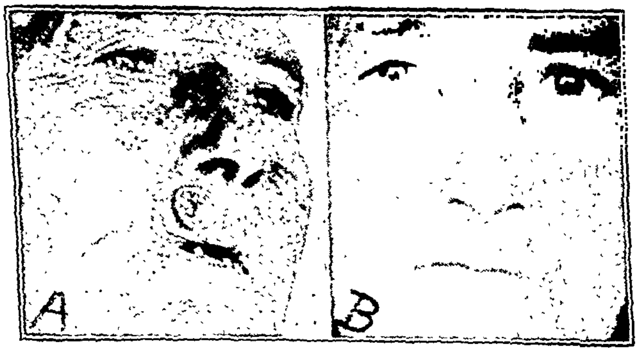

Fig. 1.—*A*, basal cell epithelioma of the upper lip in a woman, aged 72, referred by Dr. William Hamilton of Philadelphia. One desiccation treatment was given in September, 1914. *B*, result. Note absence of contracted scar. *No recurrence in nearly four years.*

In addition to the desiccation or coagulation of tissues and the sealing of blood and lymph channels, the heat penetrates beyond the area totally destroyed and devitalizes malignant cells without impairing the healthy tissue, thus lessening the likelihood of local recurrence or metastasis and conserving the maximal amount of normal tissue.

Blood vessels encountered in the oral cavity are blocked by the current, and secondary hemorrhage rarely occurs. The efficiency of electrothermic methods is increased in some cases by the judicious use of operative surgery, the roentgen ray and radium.

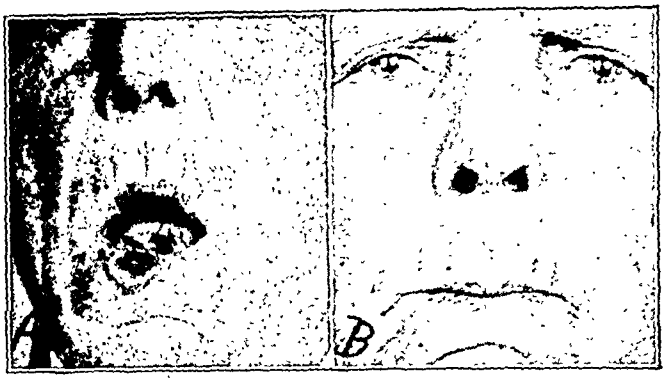

Fig. 2.—*A*, epithelioma of lower lip, a recurrence after surgical excision, in a man, aged 75, referred by Dr. Paul Cassidy of Philadelphia. One desiccation treatment under local anesthesia was given in April, 1915. *B*, result of treatment. Note absence of contracted scar and regeneration of lost tissue in lip. No recurrence in more than three years.

ELECTROTHERMIC METHODS

The methods to be considered are electrodesiccation and electrocoagulation. The desiccation method is one by means of which malignant growths of small or moderate size may be destroyed by the utilization of heat of just sufficient intensity to desiccate or dehydrate the tissues, and is produced by a monopolar high frequency current of the Oudin type, which is applied to the lesion by means of a steel needle or other pointed metallic applicator (usually steel knitting needles) which may be cut and curved, if necessary, to suit the case under treatment. The desiccation method is of advantage when the lesion is localized and a good cosmetic result is to be desired, and is subject to such control as to area and depth that a very small growth even on the cornea may be successfully treated without injury to vision, as may a growth on the vocal cords be destroyed without impairing phonation. The very slight trauma and absence of secondary inflammation probably explains the absence of scarring and the success obtained in treating delicate structures.

Electrocoagulation is produced by a bipolar high frequency current of the d'Arsonval type, is more penetrating and intense in action than the desiccation method, and is utilized to destroy large growths, including those that involve bone.

There are many variations of technic in the application of both methods to suit the requirements of the individual case, which need not be considered in detail here.[1] The heat from high frequency currents, unlike that from the thermocautery and galvanocautery, is not transmitted by contact, but is generated within the tissues by the resistance offered to the current. The cautery is comparatively superficial in action, while the high frequency current under proper conditions will penetrate and destroy tissue to any depth, in parallel or divergent lines, depending on the size and arrangement of the electrodes, and also the strength and quality of current, which are varied to suit indications.

---

* Read before the Section on Stomatology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

L.: Electrical Desiccation as an Adjunct to Surgery, with Special Reference to the Treatment of Cancer, ibid., August, 1912; The Desiccation Treatment of Congenital and New Growths of the Skin and Mucous Membranes, The Journal A. M. A., Sept. 12, 1914, p. 925; Electrothermic Methods in the Treatment of Rodent Ulcer, Urol. and Cutan. Rev., November, 1917.

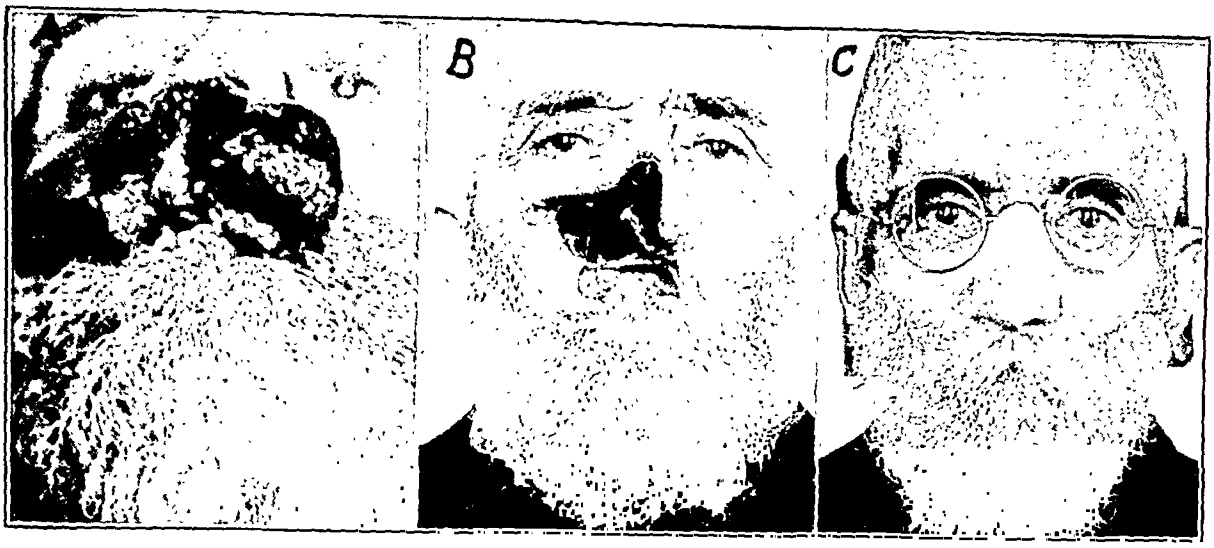

Fig. 3.—*A*, epithelioma involving upper lip, antrum, septum, nose, alveolus and hard palate, of three years' duration, in a man, aged 66, referred by Dr. J. D. Graber of Royersford, Pa. Previous treatment by plasters and the roentgen ray had been unsuccessful. The case was pronounced hopeless from a surgical standpoint by Dr. John Chalmers DaCosta of Philadelphia. One electrothermic coagulation treatment under ether anesthesia was given, March 1, 1916, and two slight recurrences were treated under local anesthesia by the desiccation method. *B*, final result, with no recurrence in two years and five months. *C*, reconstructed features by the sculpture method executed by Major R. Tait McKenzie of Philadelphia and Mrs. Alan Chesney of Baltimore. A plaster cast was made and the lost features built out in clay. A copper plate of suitable thickness was deposited on the cast by electrolysis and then silver plated. This plate was painted to match the tint of the skin, the mustache added and the plate attached to the rims of the glasses. A similar plate may be kept in place by means of spirit gum without the aid of the glass frames if desired. A plate is under construction to replace the hard palate and with artificial upper and lower teeth, in the hope that the patient may improve articulation and better masticate his food.

OPERATIVE SURGERY, THE ROENTGEN RAY AND RADIUM

When the antrum or other structures not easily accessible are involved, or when normal tissues cover the growths, operative surgery should be practiced as a preliminary to expose the lesion or to extirpate the gross mass of malignant tissue, followed immediately by the electrothermic treatment to check hemorrhage and to reach malignant tissue not possible to reach by the scalpel or bone-cutting instruments.

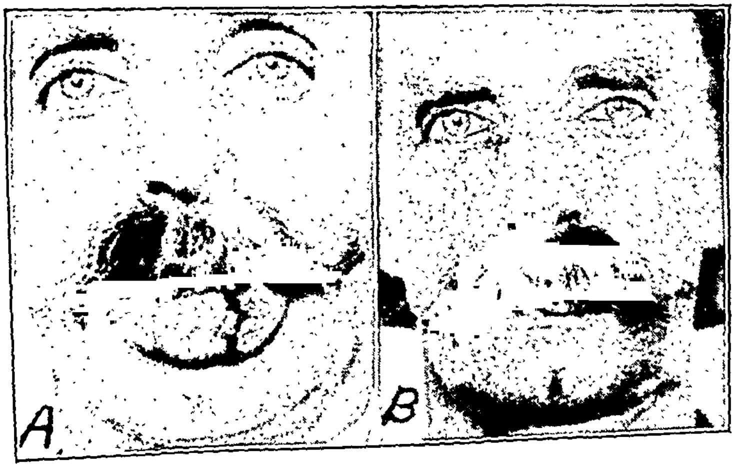

Fig. 4.—*A*, epithelioma involving the whole of the lower lip, in a man, aged 48, referred by Drs. G. C. Bird and J. F. Ulman of Philadelphia. One desiccation operation to the lip was performed under local anesthesia. *B*, result of desiccation treatment. Note absence of contracted cicatrix and regeneration of lost tissue. No recurrence in lip in four months.

When involved cervical glands are to be removed, excision must be practiced because it would be dangerous to work with the current near vital structures in the neck.

Before large growths at the base of the tongue, epiglottis, larynx or esophagus are treated, a tracheotomy should be done first and the larynx packed from below to prevent aspiration of toxic or other secretions. The ligation of the external carotid, and in rare instances the common carotid, may be practiced as preliminary to the treatment of some growths of the throat. Hemiplegia may occur, however, in the latter instance.

Deep, cross-fire roentgen therapy, according to standard technic, should be applied to the neck after dissection of the cervical glands, with the hope of preventing recurrence. When the glands are not involved, the roentgen ray should also be applied to them after electrothermic treatment of the primary lesion. The roentgen ray is of more value in the latter instance than in the former, as its use often prevents involvement of the glands, and when they are involved the roentgen ray will often retard the progress of the disease. Deep, cross-fire roentgen therapy may be used following electrothermic destruction at the site of the primary lesion to reach possible outlying cancer cells, as may radium, especially within the mouth; but the same area should never be treated by both the roentgen ray and radium. I have never seen any benefit result, however, from the use of the roentgen ray or radium alone in the treatment of cancer within the oral cavity, but the roentgen ray is of undoubted value as an adjunct to electrothermic methods and surgery.

CLINICAL OBSERVATIONS

Cancer of the mouth occurs more frequently in men than in women. The great majority of persons suffering from malignant lesions within the mouth have all their lives been insanitary or careless in the care of their mouth and teeth. Indifferent dental work or rough teeth causing continued irritation has been found to be a predisposing cause in many cases of mouth cancer, for the disease begins exactly at the site of the area which has been subject to a continued irritation.

Permanent bridge work and poorly fitting plates permitting the retention of food, and irritation to the gums are also factors in the development of malignant disease in the mouth. The removable bridge is best, and great care should be taken by dentists in properly fitting and adjusting plates.

Leukoplakia, papillomas, angiomas, chronic stomatitis, root abscesses and fistulas should be appropriately treated as a prophylactic measure against the development of malignant disease.

The irritation caused by excessive smoking is a contributory factor to the development of leukoplakia and mouth cancer, especially in those who fail to keep their mouth and teeth clean.

A striking number of mouth cancer patients are also syphilitic, and a combined tertiary lesion and cancer is not uncommon. This is true also of tuberculous lesions.

All papillomas or ulcers in the mouth showing a tendency to progress, unless the lesion is positively and purely syphilitic, should be treated just as though they were cancer, regardless of the pathologic finding, as all papillomas are potentially malignant.

A section should never be taken for pathologic examination except immediately before operation, if this seems necessary. A frozen section can be made and a diagnosis returned in ten minutes. By excising a piece of tissue for examination and waiting one or two weeks for a report, one will probably find that metastasis or rapid extension of the disease has taken place, owing to the opening of blood and lymph channels.

Before treatment is begun in any case of mouth cancer, a careful stereoscopic roentgenographic study should be made to detect possible bone or antrum involvement. Transillumination tests also should be made as a confirmatory diagnostic measure.

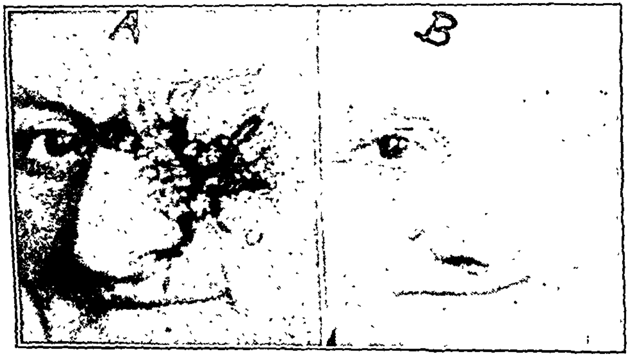

Fig. 5.—*A*, epithelioma involving nose, cheek, brow, eyelid, globe, and bones of orbit and antrum in a woman, aged 59, referred by Dr. T. L. Bradford of Philadelphia. Roentgen treatment had previously been used unsuccessfully. One intensive electrothermic coagulation treatment under ether anesthesia was given in March, 1917. *B*, result of one treatment. No recurrence in year and a half.

Success in the treatment of cancer is obtained only by absolute eradication of the last vestige of disease, else it will surely recur, and will progress more rapidly than if left alone.

Malignant lesions occurring in the mucous membranes are usually of the squamous cell type. They progress rapidly and metastasize early, in contradistinction to the basal cell or rodent ulcer type occurring on cutaneous surfaces, which progress slowly and seldom metastasize. If the mouth cases are localized and treated by electrothermic destruction and the cervical glands treated by the roentgen ray, a fair percentage of cases will be clinically cured.

The prognosis of cancer of the mouth with cervical glandular metastasis is always bad, no matter how early seen, yet a small percentage of patients recover after appropriate treatment, and it is worth while to attempt treatment when the glands are movable and not adherent. When the glands are adherent and other structures in the neck are involved, it is not worth while attempting treatment except for palliation. In early diagnosis and treatment lies the only hope.

Lip cases and small lesions within the mouth may be treated under local anesthesia; but if the lesion is advanced, general anesthesia should be employed to insure thorough destruction.

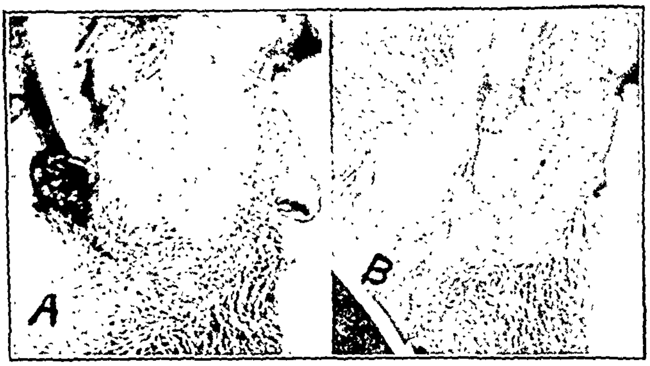

Fig. 6.—*A*, basal cell epithelioma, involving tissue and bone at angle of jaw, in a man, aged 73, referred by Dr. John Hedges of Philadelphia. The roentgen ray had previously been used without success. One desiccation treatment under local anesthesia was given in March, 1917. *B*, result of one treatment. Note absence of contracted scar. No recurrence in one year and a half.

ANALYSIS OF TWO HUNDRED CASES OF CANCER OF THE ORAL CAVITY, JAWS AND THROAT

Two hundred cases were treated by one or both of the electrothermic methods or in combination with surgery, the roentgen ray and radium. Surgery was used when the lesions were inaccessible to the current, when it required the incision of healthy tissue to expose the growth, or when it was necessary to excise the glands. In the majority of these cases the roentgen ray, radium or both had been used before without success, in which case these agents were not used again. When the roentgen ray or radium had not been employed before, one or both measures were used in combination with electrothermic methods, when judgment indicated the wisdom of so doing.

Two types of cases were selected for the series. First, those that were distinctly localized in which a guardedly favorable prognosis could be given, and second, those which had metastasized to the cervical glands, but the glands were movable and not adherent to the tissue of the neck, in which the prognosis was

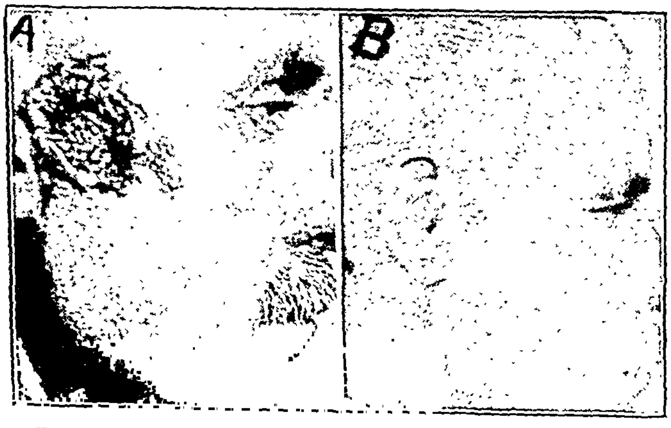

Fig. 7.—*A*, rodent ulcer involving bone of maxilla and mandible, of three years' duration, in a man, aged 50, referred by Dr. William H. Schmidt of Philadelphia. One electrothermic coagulation treatment was given under ether anesthesia in April, 1915. *B*, result. No local recurrence in eight months, when patient died with what was diagnosed as abscess of the brain by the attending physician, but which may have been metastasis.

unfavorable, but judgment indicated there was a chance of success if treated by combined measures.

Numerous other very advanced cases, in which the primary lesion was very extensive, with adherent metastatic glands, and involvement of other structures in the neck, were either declined as absolutely hopeless or else treated palliatively with no thought of cure, but sometimes to destroy a growth on the tongue or in the throat to ease temporarily the respiratory function or to render the intake of nourishment possible or more comfortable, and with the idea of alleviating pain and prolonging life.

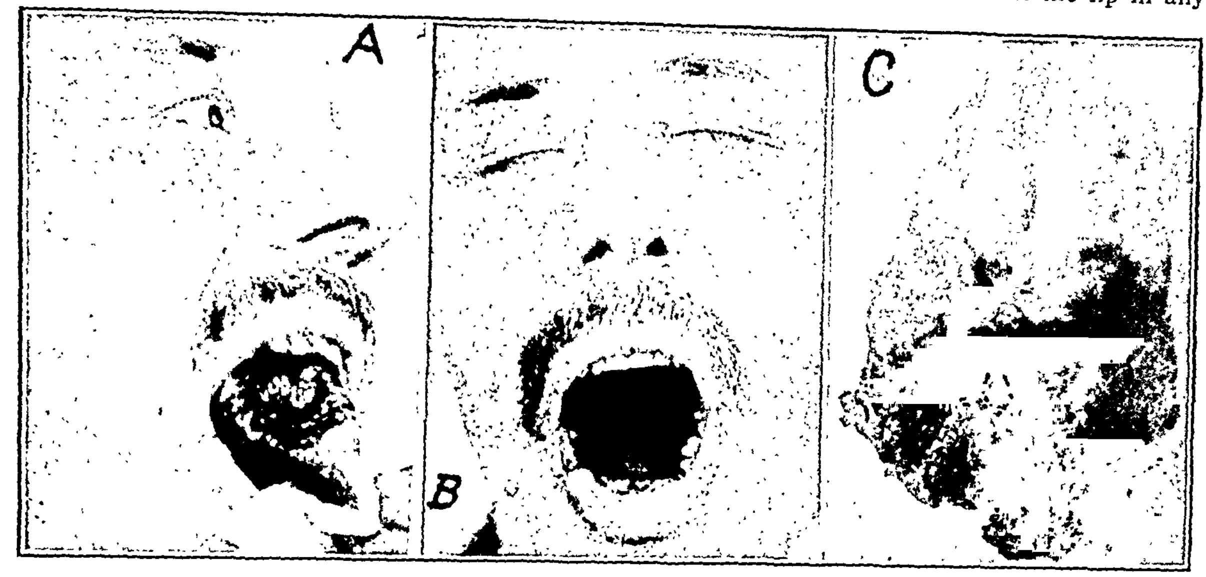

Fig. 8.—*A*, advanced squamous cell carcinoma of the tongue of four months' duration in a man, aged 46, referred by Drs. John B. Deaver and Walter Ziegler of Philadelphia. The cervical glands were involved and treated by the roentgen ray. The tongue was amputated at the line of the tonsils by the electrothermic coagulation method under general anesthesia, without hemorrhage. Little pain or discomfort followed the operation. *B*, result after electrothermic treatment. No local recurrence in two months. This photograph is shown to demonstrate the practicability of amputation of the tongue by the electrothermic method. *C*, tongue in another case immediately after amputation by this method. Note coagulated area at distal end.

The distribution of the cases treated and the results obtained are presented in the accompanying table. A brief outline is necessary to complete the presentation:

1. *Upper Lip.*—Localized: The nine cases of epithelioma of the upper lip, some of which were advanced, though without metastasis, were all treated once by the desiccation method, under procain-epinephrin anesthesia, and there has been no recurrence in from six months to four years.

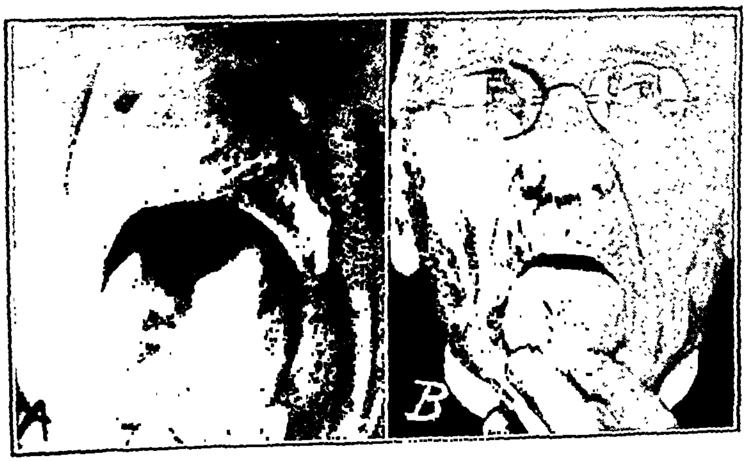

Fig. 9.—*A*, epithelioma of tongue of six months' duration in a man, aged 74, referred by Dr. J. C. Biddle of Fountain Springs, Pa. *B*, result of desiccation treatment under local anesthesia in May, 1911. There were enlarged glands on both sides of the neck in this case, which were probably inflammatory, since they disappeared after the treatment of the tongue lesion and the application of the roentgen ray to the neck. There was no recurrence in four and one-half years, when the patient died of some other disease.

2. *Lower Lip.*—Localized: The sixty-one localized lower lip cases were all treated under local anesthesia by the desiccation method. There has been no local recurrence in any case in from three months to eight years. In one case a cervical gland became involved two years after treatment of the lip and was excised by Dr. Charles Nassau of Philadelphia, with no recurrence in two years.

Metastasis: Of the three lower lip cases with glandular involvement, the primary lesion was treated by desiccation, and the glands were excised under the same anesthetization and the roentgen ray employed. There was no local recurrence in the lip in any case, but there was recurrence in the neck in two cases from which patients died. There was no recurrence in the third case either in lip or neck in two years.

3. *Alveolus* (*Upper Jaw*) *and Hard Palate.*—The thirteen cases involving the alveolus and hard palate were treated by the coagulation method under general anesthesia. In eight there was no recurrence in from three months to three years. Four recurred and were lost track of, while the other one is now under treatment again.

4. *Alveolus* (*Lower Jaw*) *and Floor of Mouth.*—Localized: Of the twelve localized alveolus and floor of mouth cases treated by electrocoagulation, six patients have remained well for periods of from three months to four years. Two had no local recurrence, but glands became involved, and four had both local recurrence and cervical metastasis.

CASES OF CANCER TREATED AND RESULTS OBTAINED

	Localized			Cervical Metastasis		
		Result			Result	
Anatomic Location	No.	No Recurrence	Recurrence	No.	No Recurrence	Recurrence
1. Upper lip	9	9	0	0	..	..
2. Lower lip	61	61	0	3	1	2
3. Alveolus (upper jaw) and hard palate...	13	8	5	0	0	0
4. Alveolus (lower jaw) and floor of mouth	12	6	6	10	1	9
5. Tongue	15	10	5	6	2	4
6. Buccal surface	14	8	6	7	0	7
7. Antrum	2	2	0	0	0	0
8. Tonsils	5	3	2	2	0	2
9. Pharynx	2	1	1	0	0	0
10. Epiglottis, larynx, base of tongue and esophagus	3	0	3	0	0	0
11. Advanced lesions involving several structures in mouth	13	5	8	23	5	18

Metastasis: Of the ten cases involving the alveolus and the floor of the mouth with metastasis, only one patient has remained free from recurrence, and he has been well three years. Three remained well for periods of from three months to one year, but finally there was recurrence in the neck. In the remaining six, recurrence followed in a short time, and were soon beyond the hope of benefit.

5. *Tongue.*—Localized: Of the fifteen localized tongue cases, seven were treated by the desiccation method under local anesthesia, and eight by the coagulation method under ether anesthesia. There was no recurrence in ten cases in from three months to five years. Two recurred locally, and the glands became involved. These patients were treated again, but unsuccessfully. In three there was no local recurrence, but the glands later became involved. These patients reported too late for further treatment.

Metastasis: The six tongue cases with cervical involvement were treated by combined coagulation, surgery or the roentgen ray. One patient remained well for four and one-half years, when he died of some stomach trouble (Fig. 9).

Another has been well two years. Two had no local recurrence, but there was recurrence in the neck, and two had recurrence both in the tongue and in the neck. They were not treated again.

6. *Buccal Surface.*—Localized: Of the fourteen buccal surface localized cases, eight patients have remained well after electrothermic treatment for periods ranging from four months to four years. The other six cases recurred either locally or the glands became involved, and they were not treated again.

Metastasis: Of the seven buccal surface cases with glandular involvement, all recurred either locally or in the neck, and soon were beyond hope.

7. *Antrum.*—The two antrum cases were treated first surgically and then by electrocoagulation. There was no recurrence in one case in fifteen months and in the other in two years.

8. *Tonsils.*—Localized: Of the five localized tonsil cases, three have not recurred in from one to two years. Two had local recurrence and the glands became involved and could not be treated again.

Metastasis: Both cases recurred locally in the neck and were not treated again.

9. *Pharynx.*—One case soon recurred locally, but the patient is well three months after a second treatment. The other recurred locally and involved structures that were inaccessible and could not be treated again.

10. *Epiglottis, Larynx, Base of Tongue and Esophagus.*—These three cases were all unsuccessful. One patient died of pneumonia a few days after treatment, probably owing to aspiration of secretions, a preliminary tracheotomy not having been performed. The second patient died of secondary hemorrhage two weeks later. There was recurrence in the third case, and a second operation was not attempted.

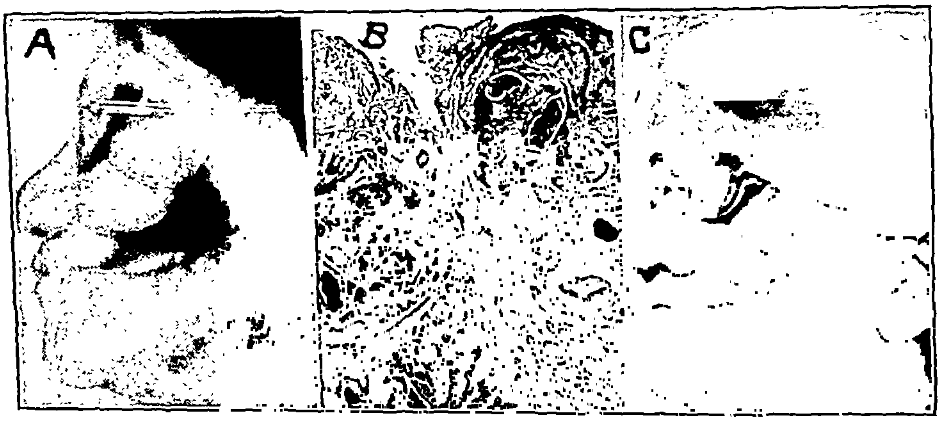

Fig. 10.—Squamous cell carcinoma involving antrum, alveolus, hard palate and buccal surface on left side in a woman, aged 60, referred by Dr. E. B. Miller of [illegible] involvement was extensive in this case and some of the diseased tissue was [illegible] surgical removal was done by Dr. G. M. Dorrance, followed immediately by [illegible]. *A*, result of this treatment. No recurrence in fifteen months; *B*, low power photomicrograph (showing prickle cells) on which diagnosis was based; *C*, result of plastic operation in which tissues were separated from bony attachments, and cheeks drawn together and sutured.

11. *Advanced Lesions Involving Several Structures in Mouth.*—Localized: Five of these thirteen patients have remained well for periods ranging from three months to two years. In the remaining eight cases there was local recurrence, and the glands became involved, rendering them hopeless.

Metastasis: Of these twenty-three cases, five remained free from recurrence from three months to one year. The others all recurred and soon were beyond hope of benefit.

When the lesions recur only locally, there is a chance of success if the patient is treated a second or, indeed, a number of times; but if there is recurrence in the glands of the neck, further treatment is usually of no avail.

The basal cell, or rodent ulcer, type of epitheliomas occurring on cutaneous surfaces, even though advanced and with bone involvement, is so satisfactorily treated by the desiccation and coagulation methods, that these lesions practically all recover when treated thoroughly.

It will be seen that the chances of success in cancer of the oral cavity vary with localization, the anatomic location and the presence or absence of glandular involvement.

The foregoing analysis of results obtained in 200 cases, and the illustrations, will serve to give an idea of the rôle the desiccation and electrothermic coagulation methods can be expected to play in the treatment of cancer of the oral cavity, jaws and throat, and in which types of cases the use of operative surgery, the roentgen ray and radium in combination is justifiable.

Medical Arts Building.

THE USE OF HEAT AND RADIUM IN THE TREATMENT OF CANCER OF THE JAWS AND CHEEKS*

G. B. NEW, M.D.
ROCHESTER, MINN.

Cancer of the jaws and cheeks is one of the most malignant forms of new growth. The type that is primary in the cheek is probably only exceeded in its malignancy by the melano-epithelioma. Little is known regarding the causation of such growths except that chronic irritation of some sort is believed to be an important factor, and, this being true, every snag of tooth or any other source of irritation should be eliminated from the mouth as a prophylactic measure. While tobacco may be a cause in some cases, it probably has not so much importance as is usually attributed to it. The man with cancer of the cheek who chews tobacco has, as a rule, carried the tobacco on the unaffected side of the mouth. Syphilis is undoubtedly a factor in the production of cancer of the tongue, but is of no demonstrable consequence in relation to cancer of the jaw and cheek. Papillary leukoplakia frequently develops into epithelioma, and it should be thoroughly treated with cautery and radium.

Fifty-seven cases of cancer of the jaws and cheeks were examined at the Mayo Clinic during 1917. Thirty-two of the patients were inoperable; four had glandular involvement, but operation was considered advisable and a block dissection was done in addition to the treatment of the local growth. Twenty-one had no glandular involvement and were treated with the cautery and radium. Data concerning these twenty-one patients form the basis of this paper. In most instances epitheliomas occurred in the fifth decade. There were two patients between 31 and 40 years of age; four between 41 and 50; twelve between 51 and 60, and three between 61 and 70. Nineteen were men and two were women. The patients had first noticed the trouble from two weeks to four years before they came for examination, but it was difficult to determine the length of time the growth had been present or active. The tumor was located on the lower jaw in two cases, on the lower jaw and cheek in seven, on the upper jaw in two, on the upper jaw and cheek in seven, and on the cheek in three. Five of the twenty-one patients had been operated on before coming to the clinic. Seven of the epitheliomas were associated with, and apparently had originated in, a leukoplakia. In one case, the tumor developed on a pathologic fracture of a bone cyst of the jaw.

* Read before the Section on Stomatology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

TREATMENT

In reviewing the literature, it is seen that the usual method employed in the treatment of cancer of the jaws and cheeks has been a complete or partial resection of the jaw with some type of plastic operation if the growth involved the cheek. Recently the cautery has been used in the treatment, but I have been unable to find any report in the literature of a group of cases treated in this manner. At the Mayo Clinic the cautery has been employed for several years in the treatment of such cancers, with a few exceptions, in preference to resection of the jaws. In many instances, the radium has been used following the cautery.

During the year 1917, all the patients operated on were treated by the slow heat cautery with soldering irons, and, in addition, radium was used. While a report of recently treated cases of cancer must necessarily be only preliminary, nevertheless the results have been very encouraging, and I feel that we have obtained better immediate results than were obtained previously in the treatment of cases of this type.

In cases of cancer of the jaw or cheek without glandular involvement, the decision as to whether or not they are surgical depends on individual judgment, but in any questionable case the patient should be given the chance an operation may afford, and everything possible should be done for him.

Before operation, patients are advised that they must return for observation at least once a month during a period of six months or more following operation, so that they may have immediate care, if there is any recurrence. When the seriousness of the condition and the necessity for cooperation is explained, it is usually not difficult to get patients to return at stated intervals.

TECHNIC

After the patient is anesthetized with ether, a mouth gag is inserted opposite the affected side. The tongue is drawn to one side out of the way, by the aid of a stomach clicker. The water-cooled speculum is inserted, and all the teeth in the area involved, or those that prevent good exposure of the growth are removed. If it is possible, the entire growth is excised from the jaw or cheek with a knife cautery, and the base is cauterized with soldering irons. If this is not possible, the irons are inserted into the tumor. The water-cooled speculum prevents the burning of the lips or cheeks except in the area being treated, and it affords good exposure. A wooden tongue depressor holds the tongue out of the way and prevents it from being burned. The cautery should be used longer than seems really necessary; at least for from twenty to forty-five minutes. If the growth is in the upper jaw and involves the antrum, the soldering irons are carried up into the antrum and the entire growth is gradually burned away.

Soldering irons are found to be the most satisfactory type of cautery, as the heating element in the handle of the electric cautery usually interferes with a good view of the area that is being treated. If the irons are too hot, the surface cauterized becomes carbonized and prevents the penetration of the heat. A slow heat that gradually cooks the tumor is preferable.

Occasionally hemorrhage will occur during the first ten days or two weeks following the cauterization while the slough is clearing off and, if it is not readily controlled by packing, ligation of the external carotid with the lingual and facial branches is advisable.

About two weeks after the cauterization, most of the slough will have cleared off, and radium may be applied directly into this open area. It is directed into the ulcerating area on lead applicators, using a 50 or 100 mg. tube within a silver tube, for from fifteen to twenty hours, without screening. If the growth has involved the cheek, radium is applied with screening externally over the cheek, thus cross-firing. If the growth has involved the antrum, the radium is placed in the antrum, packed there with petrolatum gauze, and left in place for the period of hours required by the particular type of lesion.

In from a month to six weeks after the operation, large pieces of sequestrum usually come away from the jaw. These pieces are somtimes one-fourteenth to three-eighths inch thick. In a month from the time the first radium treatment is completed, further treatment is given and repeated as often as the condition indicates. If there is any recurrence noted a second cauterization is done, and this is followed by radium.

Epithelioma of the jaw does not, as a rule, metastasize early, unless there is considerable involvement of the cheek. In such a case, the submental and submaxillary glands on the affected side should be removed.

RESULTS

Of the twenty-one patients treated, twenty were traced; of these, fourteen have been free of local recurrence for from six to eighteen months. One patient recauterized three months previously, thus far has no recurrence. One died of lymphatic leukemia six months after operation; there was no recurrence. Two of the fourteen patients (one with epithelioma of the cheek and one with epithelioma of the upper jaw and cheek) have developed glands of the neck and have had block dissections. Thus twelve of the twenty patients have had no recurrence locally or in the glands for from six to eighteen months. One patient has a hopeless local recurrence. This patient was operated on before coming to the clinic. Two patients died of the cancer; one of these had been operated on before coming to the clinic; one consulted a plaster doctor, and his present condition cannot be learned from his letter. There was no operative mortality.

This group of cases shows that our immediate results in the treatment of epithelioma of the jaws and cheeks without glandular involvement, by the use of the cautery and radium, have been very encouraging. The end-results cannot be foreseen, but we believe that by the addition of radium to the treatment, much more is being accomplished than formerly.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CLARK AND NEW

Dr. A. J. Ochsner, Chicago: I am not familiar with this method. My observations are based entirely on the treatment of these growths with the actual cautery. I have used this method most successfully. Many of my patients remain well for many years following the use of the soldering iron, whereas if the same growth is removed by the electric cautery or even the Paquelin cautery the result is not so good. I believe that is due to the fact that the heat of the soldering iron penetrates deeper and produces more destruction at a distance from the point of application of the soldering iron. It is quite possible that Dr. Clark's method accomplishes the same thing and in a much nicer way than the soldering irons do. The mortality among these patients when operated on early is practically nil; when operated on late, death in the earlier group of cases was either from shock or from pneumonia. We thought that our successful cases depended on the fact that we destroyed the growths to a very great distance from the originating point and that we held the red hot soldering iron in position for a considerable period of time, that is, we do not brush it back and forth, because in that way you do not reach the depth, so that boiling of the tissues has seemed to be of especial value, and especially so in the cases that are seen early. Of course, these patients do not come to the general surgeon as early as they do to the dentist, so that it is rare that we see a real early case of malignant growth of the jaw. In the last three years we have used the roentgen ray in all cases and radium in a considerable number of cases. In the cases of circumscribed osteosarcomas we have excised the jaw. In the carcinomas we have not done this, but we have cauterized very deeply. In malignant polypus of the antrum we have found many cases that have been treated for a long time on the supposition that they were due to infection of the antrum, and the patients have come late for that reason. In cases of that kind, in which we removed the eye at the primary operation, we have had permanent results. In cases in which we have tried to save the eye we have not succeeded.

Dr. Bertha Van Hoosen, Chicago: For three years I have had encouraging results from the use of emetin in the treatment of malignant disease. I have never seen a case of malignant disease of the jaw where the patient did not have pyorrhea or badly diseased gums. Emetin seems to produce a fibrosis. I have at present two patients who, without any operation, are practically cured of malignant disease. One has a squamous cell carcinoma of the labia. The other has a very extensive medullary carcinomatosis and has made wonderful improvement.

It seems to me that in the inoperable cases Dr. Clark might succeed in localizing the disease and making the surrounding tissues more healthy, by starting up a fibrosis, using at least 5 grains of emetin the week before his treatment is begun. Thus he might make it successful in every case instead of the small percentage reported.

Dr. Robert Abbe, New York: It is not through the blood stream, except where the blood stream has been infected and the metastatic particles are carried in it, but through the lymph channels that we are bound to search for absorption. We have to reach the original infection, and heat, roentgen ray and radium seem to be the agents of choice. That the cells that are wandering away from the lymphatics are more sensitive than normal malignant cells has been proved by biologic study. By electronic action one can produce either a slight or a very marked arrest of growth, or a destruction of those cells. The heat method is one by which the cells in some denfiite area are arrested, destroyed or absorbed. The heat can be driven into these cells, if we go far enough. There is no question but that the lymphatics can be treated at a distance. In the cases of cancer of the mouth spoken of by Dr. New, it seems to me that the question of tobacco as a cause is absolutely proved in nine cases out of ten. If you ask the question of these patients you will find they have smoked to excess three to five cigars a day or a corresponding amount of tobacco in any form, and where the quid is carried in the cheek it is a cause of carcinoma of the buccal site. Dr. G. H. Davis proved that in the Philippines chewing of the Betel leaf was the cause of carcinoma of the inside of the mouth. I believe we can state that tobacco is the cause of most cases of carcinoma inside of the mouth.

Dr. William L. Clark, Philadelphia: The success obtained by the use of the desiccation and electrothermic coagulation methods in the treatment of cancer is explained by the fact that the malignant tissue was all destroyed, and when possible with one radical treatment, while at the same time blood and lymph channels were sealed. In cases in which, by error of judgment, some of the diseased tissue was not destroyed, recurrence was the rule; indeed, owing to the stimulation of the electric current, the disease often manifested greater activity than would have been the case if left untreated. In cases of recurrence, however, the electrothermic methods have often been applied twice, or even a number of times, before final success was attained, but the practice of intentionally treating a malignant lesion in a series of electrothermic operations is a reprehensible one, and must be discouraged in no uncertain manner. It is quite as irrational to do this as to excise a cancerous growth surgically in a series of operations with the hope of success. The term "fulguration" is applied in the United States to any type of high frequency spark that will cause the destruction or burning of tissue. Fulguration used in this sense is a misnomer, since the original deKeating-Hart fulguration method does not destroy tissue, but is applied to the field of operation after radical surgical ablation of cancer in the form of long high-tension sparks, not for the purpose of destroying tissue, but to alter local nutrition, and it is claimed by Hart, Bainbridge and other advocates, that recurrences are less frequent when fulguration is used in combination with surgery, than when surgery is used alone. I have had insufficient experience with this method to venture any comment on the truth or fallacy of this claim. I may say, however, that the pseudofulguration method employed in this country means little, as the destruction or burning of tissue by any sort of high frequency spark whatsoever is called "fulguration," hence, in the hands of different men, entirely different effects on the tissues may be produced.

The indiscriminate use of the high frequency spark in the treatment of cancer by frequent applications and incomplete destruction has justly brought the destructive fulguration method into disrepute. The term fulguration should be abandoned, except when used according to the technic of deKeating-Hart. On the other hand, desiccation and electrothermic coagulation are descriptive of the actual effects on the tissues, and these effects are produced by definite types of high tension electric currents of known strength, capacity, inductance and resistance, and the methods are so standardized that they may be duplicated over and over again by any physician possessing the requisite appliances and who has learned how to use them.

It is also desirable that the operator should have a good surgical training and a comprehensive knowledge of anatomy.

Dr. Gordon B. New, Rochester, Minn.: In regard to the point concerning tobacco that Dr. Abbe has brought up: Too much stress has been put on the effect of tobacco as a cause of cancers of the mouth and lip, although undoubtedly there are a large number of cases of cancer in which tobacco is a factor. Among 196 patients with epitheliomas of the lip treated at the Mayo Clinic during the past twelve months, 33 per cent. did not use tobacco at all. Since this is about the percentage of men who do not smoke, it does not bear out the high percentage of cases in which tobacco is a factor.

Cold Conduces to Shock.—Exposure to cold has a marked effect in inducing or augmenting the state of shock. A badly wounded man leaves the front-line trenches in a fair condition, but during his journey to the rear he loses heat by sweating and exposure, and then passes into the shocked state. His condition is likely to be much improved when he is placed in a warm bed and supplied with sufficient heat to restore his normal temperature. It seems probable that cold, which is known to cause stagnation of blood capillaries, increases the "lost blood" by helping to induce capillary stagnation.—*Review of War Surgery and Medicine.*

TREATMENT OF VERTEBRAL TUBERCULOSIS BY FUSION OPERATION

REPORT OF TWO HUNDRED AND TEN CASES *

RUSSELL A. HIBBS, M.D.
NEW YORK

In these 210 cases of vertebral tuberculosis, the patients were operated on at the New York Orthopedic Hospital in the period of January, 1911, to January, 1915, so that at this date, June, 1918, seven years have elapsed since the earliest and three and one-half years since the latest patient was operated on. This is a sufficient length of time to make possible a fair estimate of the influence of the operation on the course of the disease.

The operation was designed and its technic perfected with the single object of eliminating motion of the diseased articulations, experience having proved that the limited motion obtained by various mechanical means, such as braces, corsets, etc., was beneficial. It was felt that absolute elimination would hasten the cure and perhaps prevent deformity. The absolute elimination of motion in any joint is accomplished only when the bones entering into its formation become fused. This is possible only when all tissue other than osseous is removed or destroyed from between their articular ends and new bone formation fills the gap. This is sometimes accomplished by nature without operative aid. In the case of a vertebral joint affected by tuberculosis, however, nature is too slow. The spinous processes, laminae and lateral articulations are rarely involved. Their easy accessibility and close approximation make them peculiarly well adapted for operative fusion.

OPERATION

An incision is made through the skin and subcutaneous tissue from above downward over the spinous processes of the segment to be fused, exposing the tips. The periosteum over the tips of the first two spines above is split and the interspinous ligament between. With a periosteal elevator these are bared of periosteum for about one half their length. Small packs of gauze are now inserted to prevent oozing. The periosteum of each tip and the interspinous ligament between is split in turn, and the periosteum is freed from the bone and treated as described and so on including each vertebra to be fused.

Beginning at the upper end again, with a dull periosteal elevator for children, and a sharp one for adults, the operator separates the periosteum farther forward from the spinous processes and laminae to the base of the transverse processes, exposing the lateral articulation. Each vertebra is treated in this manner from above downward and packings inserted as noted. These packs are very important, as they keep the operative field dry.

Beginning at the upper end again with a small curet, the operator curets the lateral articulations and removes the periosteum and ligament from the adjacent edges of the laminae and bases of the spinous processes. This is done with each vertebra in turn over the entire field, with packs inserted as described.

Beginning at the upper end again with a small chisel, the operator elevates a piece of bone from each lamina and turns it from above downward, its free end resting on the one next below. Each in turn is so treated with packings inserted afterward.

With the operator beginning at the upper end again with a bone forceps, each spinous process is carefully cut and fractured, so that its tip rests on the bare bone next below. The periosteum and ligament which have been split and pushed to either side and lie in practically an unbroken sheet, are brought together in the middle and sutured with interrupted sutures of ten-day chromic catgut. The subcutaneous tissue is closed by a continuous suture of plain catgut. The skin wound is closed with a continuous suture of ten-day chromic catgut. Sterile dressings are applied and an immobilizing brace.

Summary: All tissue other than osseous has been removed from between the lateral articulations, the laminae and the spinous processes, and bone contact is secured at the lateral articulations, the laminae and the spinous processes, so that with the periosteum closed, we have practically a tube of periosteum filled with live, healthy bone, lying in continuous contact and insuring a perfect fusion.

Great care should be exercised in the removal of all tissue from the bones, as the area of fusion will be determined absolutely by the thoroughness and extent of the dissection. If the dissection is made subperiosteally, there is absolutely no difficulty from hemorrhage, and the whole operation may be done with practically a dry field.

The number of vertebrae to be fused in each case is determined by the extent of the disease. Great care should be exercised that two healthy vertebrae are included at either end. As will be seen later on, in some cases a sufficient number of vertebrae were not included, and it became necessary to perform a second operation.

The patient is kept quiet in bed for eight weeks after the operation and continues to wear a brace for from six months to a year. The form of brace used is the Taylor model, because it is accurate, and is the most efficient means of securing immobilization after operation. It is always fitted to the patient before operation, and is, therefore, perfectly comfortable.

In this group of cases, there has been no operative mortality and all the wounds have healed by first intention. There has been practically no shock in any case.

In dealing with these patients, we have always had in mind the fact that they were suffering from tuberculosis, and, when possible, every influence, such as good food and good air, has been brought to bear on them. An attempt has been made to keep every patient under constant observation, and in most instances this has been done by the visiting nurses and our dispensary department. The patients all come from among the poorer classes and most of them live in crowded tenements.

No attempt has been made to select cases. Every patient with Pott's disease who would consent to operation and whose general condition warranted the administration of an anesthetic, was operated on, regardless of other complications or the extent of the disease. I believed that the operation would hasten the cure of many and for those in whom cure could not be expected, it would at least contribute to their comfort. Most of these patients had had some form of brace or jacket treatment before operation.

---

* Read before the Section on Orthopedic Surgery at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

RESULTS OF OPERATIONS

The first patient was operated on Jan. 9, 1911, and during the intervening period 210 patients have been operated on. One hundred and fifty-seven, or 74.7 per cent., were cured. Twenty-two cases are doubtful cures, and thirty-one patients are dead. In the classification of the cured cases, every one concerning which there is the slightest doubt has been excluded and only those included which show no evidence of disease, as determined by the most careful examination, with complete knowledge of their history since operation. The patients have all been examined by the staff working as a group within the past month. Photographic, roentgen-ray and tracing records have been made of every case before operation and at frequent intervals since, and it is felt that among all those recording deformity, the most reliable records are carefully made tracings. The results are set forth in the accompanying tables.

In many of these cases, a definite fusion of the bodies also was shown by the roentgen ray. This would be expected only in the articulations of which the cartilage had been destroyed by disease.

Deformity.—In 139 cases there was no increase in deformity. In eighteen cases there was definite increase. In all cases, there is an amount of diminution in the deformity from the operation, which is due to a transposition of the spinous processes. This is of some importance to the patient.

TABLE 1.—AGE OF PATIENTS AT TIME OF OPERATION

No. Cases	Age*	No. Cases	Age*
2	between 1 and 2 years	6	between 15 and 20 years
27	between 2 and 4 years	5	between 20 and 30 years
22	between 4 and 6 years	3	between 30 and 40 years
47	between 6 and 10 years	2	between 40 and 50 years
43	between 10 and 15 years		

*The average age was 14 years plus.

TABLE 2.—DURATION OF DISEASE AT TIME OF OPERATION

No. Years*	No. Cases	No. Years*	No. Cases
Less than 1 year	38	From 6 to 10 years	28
From 1 to 2 years	17	From 10 to 15 years	18
From 2 to 4 years	30	From 15 to 20 years	1
From 4 to 6 years	25		

*The average duration of disease at the time of operation was 4.6 years.

No attempt has been made to correct deformity by the exercise of force at the operation. The definite increase of deformity in these eighteen cases is certainly not due to destruction of bone, therefore it must be due to a developmental change, as they were all cases of disease among growing children.

Every patient in this group is living the normal life fitted to his age, either at school or at work.

There were five deaths of patients who were definitely cured of Pott's disease; two of these died of heart disease and three of pneumonia. These cases could be fairly classified as cured, but they are not included in the 157 cases.

Doubtful Cures.—There were twenty-two doubtful cures. These include every case in which the patient is not now in good condition, whether the local disease seemed cured or not, and also include two cases which had disease of the laminae at the time of the operation.

Three of these patients now have active lung tuberculosis. Two others are in school wearing braces. Two have remained paralyzed, although the fusion is complete and there is no evidence of active disease. In one case, the fusion is complete but the patient is not doing well. Three other patients are still under treatment and doing well, and the remainder have not been seen recently.

Patients Who Have Died, and Causes of Death.—Of the thirty-one who are dead, twenty-six patients were definitely not cured. All but five, however, improved to a considerable degree for a time after operation. One worked a while, and seven went to school. The cause of death in thirteen cases was miliary tuberculosis. The average age of the patients was 6.7 years. The average duration of disease before operation was 3.8 years. The average time that elapsed after operation was 2.4 years. Four of the thirteen patients were in fairly good condition before operation, and nine were in poor condition. Fusion was perfect in all but three cases. One of these had a pseudarthrosis, and in two cases the fusion was short. In one, a necropsy was done and the fusion was found complete but short.

TABLE 3.—NUMBER OF VERTEBRAE INVOLVED.

No. Cases	No. Vertebrae	No. Cases	No. Vertebrae
19	2	14	7
35	3	7	8
23	4	3	9
32	5	2	10
20	6	1	11

TABLE 4.—REGION OF DISEASE INVOLVED

Cervicodorsal	6	Lumbar	28
Dorsal	71	Lumbosacral	2
Dorsolumbar	50		

Five patients died of tuberculous meningitis. The average age of these patients was 7.6 years. The average duration of disease before operation was 3.9 years. The average time elapsed after operation was 1.3 years. One of the five patients was in fair condition before operation, and four were in poor condition. The fusion was complete in all but one case, and in that it was too short.

Four patients died of pulmonary tuberculosis. The average age of these patients was 12.7 years. The average duration of the disease before operation was 8.1 years. The average time which had elapsed after operation was 2.6 years. All were in poor condition before operation. The fusions were complete.

Three patients died of pneumonia. The average age of the patients was 5.3 years. The average duration of disease before operation was 2.5 years. The average time that had elapsed after operation was four years. All were in good condition and the fusions perfect.

TABLE 5.—GENERAL CONDITION OF PATIENTS BEFORE OPERATION

Condition	No.	Condition	No.	Condition	No.
Poor	54	Fair	66	Good	37

TABLE 6.—DURATION OF TIME SINCE OPERATION

Time Elapsed,* Years	No. Cases	Time Elapsed,* Years	No. Cases
3½ to 4	40	6	51
5	46	7	20

*The average time was 5 years plus.

Three patients died of amyloidosis. The average age of these patients was 4.3 years. The average duration of disease before operation was 1.5 years. The average time which had elapsed after operation was 3.3 years. All were in poor condition at the time of operation. The fusions were complete. Two had abscesses which discharged until death. One closed before death.

Two patients died of heart disease. Their average age was 11½ years. The average duration of the Pott's disease before operation was six years. The average time which had elapsed after operation was four years. One was in good condition and the other in fair condition before operation. Fusion was complete in both cases.

One patient, aged 2 years, died of septic meningitis, following mastoid operation. The duration of Pott's disease before the operation was one year, and after operation, three years. The condition was good and the fusion perfect.

One died of miliary tuberculosis eight weeks after operation. This patient was in very poor condition before operation, having a large psoas abscess and pulmonary involvement. Three vertebrae were involved in the disease which had had a duration of one year. Necropsy showed a perfect fusion.

One other patient died of miliary tuberculosis four months after operation. This patient was also in very poor condition before operation. The duration of the disease had been one year and three vertebrae were involved. Two patients died six months after operation. One had tuberculous meningitis, and the other miliary tuberculosis. The remaining cases go to make up the general average of three years.

It will be interesting to note that the general average life of the patients who died after operation was three years, and it seems fair to suppose the operation may have prolonged their lives as it certainly contributed to their comfort.

Patients Still Living But Not Cured.—There are five patients living who are definitely not cured. Three have disease of the sacrum and two have fusions which are too short. Two of the sacral patients probably had the disease before operation as the fifth lumbar was partially destroyed, suggesting that the first sacral region was involved. According to our records, the third case showed involvement which included only the third lumbar region. Fusion was made to the fifth and symptoms did not clear up, so it is probable that the sacrum was involved at the time of the operation.

Patients with More than One Focus of Disease.—Three patients each had a double focus. One had both foci in the dorsal region, two had a focus each in the dorsal and the lumbar, and one developed a second focus in the lumbar region following operation for a focus in the dorsal. In two of the cases, both foci were included in the first operation, and the third patient was reoperated on for the second focus. Two of the patients were among the definitely cured. One is among the doubtful.

Cases Showing Cord Pressure Symptoms.—Of the total number of patients, thirty-five showed cord pressure symptoms. Of these twenty-six were completely paralyzed, and nine slightly spastic, with exaggerated reflexes. One was in the cervicodorsal region, twenty-two in the dorsal, eleven in the dorsolumbar, and one in the lumbar. Thirty of these cases were completely cured of their paralysis and Pott's disease, and are included among the cured cases. Of the five remaining, two are living and apparently cured of the disease, although still paralyzed. Three of them are dead, one of whom developed paralysis after operation, was reoperated on and died of amyloidosis. The other two died of miliary tuberculosis. Two of the dead had disease in the dorsal region, and the other in the lumbar. Of the two living, one patient had disease in the dorsal and the other in the dorsolumbar region. The existence of paralysis is obviously no contraindication to operation.

Cases of Psoas Abscesses.—There were sixty-seven patients who had psoas abscesses. In fifty-six cases, the abscesses were single, and in eleven cases they were double. Twenty-three patients had dorsal disease, twenty-six had dorsolumbar, and seventeen lumbar. One had disease in the lumbosacral region.

Of these, forty-two patients were cured of the abscess, eleven of them being affected in the dorsal region, seventeen in the dorsolumbar, and twelve in the lumbar. Eight of the abscesses were double and thirty-six single.

Twenty-five patients were not cured. Ten were affected in the dorsal, nine in the dorsolumbar, five in the lumbar, and one in the lumbosacral region. In four cases in which the abscesses were double, one patient died of pulmonary tuberculosis, and three are among the doubtful cases. Nineteen were single. Ten of the single cases are among those classified as dead, and five among those classified as doubtful. Four patients remained the same.

The existence of abscess, whether open or closed, is no contraindication to operation, provided it is not in the field of operation.

Cases Complicated by Tuberculosis of Other Joints.—There were twenty-one cases complicated by tuberculosis of other joints. One patient had tuberculosis of the elbow, knee, and ankle. Pott's disease was apparently cured but the case is classified among the doubtful, the other joints being active. Three had involvement of the hip. One in whom the hip was not cured is classified among the doubtful. In the other two cases the hips were cured as well as the Pott's disease.

Twelve patients had knee joint involvement. In three patients the knees were not cured and in nine they were cured. In one case the disease developed after operation, the patient dying of miliary tuberculosis. In the other eleven cases, the Pott's disease was definitely cured and the patients are classified among the cured.

Two patients had involvement of the ankle. In one the ankle was cured and in the other it was not. In both cases the Pott's disease seemed cured, but only one is classified as such.

There were three cases of shoulder joint involvement. In neither patient was the shoulder cured, but in both, the Pott's disease was definitely cured and is so classified.

One patient had disease of the sternum. The Pott's disease was definitely cured and is so classified. The sternum was practically cured.

Cases of Fusion Found at Operation.—In thirty-four cases fusion of vertebrae was found at operation. The age of the patients in three cases was from 3 to 6 years; in ten cases from 6 to 9 years, in five cases from 9 to 12 years, in thirteen cases from 12 to 15 years, and in three cases more than 15 years. Four patients had dorsolumbar disease, six had lumbar, twenty-three dorsal, and one cervicodorsal. The duration of the disease at the time of operation was less than one year in two cases, from one to four years in two cases, from four to ten years in twenty-two cases; from ten to twenty years in eight cases. In five cases, fusion was found to include all the diseased vertebrae. In three of these cases, the disease was dorsal, in one dorsolumbar, and in one lumbar. From two to eight vertebrae were involved. In eight cases fusion was found to include two vertebrae, in ten cases it included three, in two cases it included four, and in five cases it included five. In two cases six were included, in one case seven, and in another nine. Thirty of these patients are in excellent condition. One is in poor condition and is classified as not cured. Two have been lost track of, and another is still receiving treatment. These last three are classified as doubtful.

Postoperative Deformities.—In considering this aspect of the cases, we must remember that the transposition of the spinous processes immediately lessens the deformity in all cases. In seventeen of the cases, however, deformity has decreased more than can be explained by this fact. Six of these cases were in the lumbar region, and although the patients had definite deformity at the time of operation, they have absolutely none now. In 141 cases the deformity remained the same or was slightly less.

In thirty-six cases there was an increase of deformity. There was a slight increase in twenty-four of these cases. In fifteen of the twenty-four patients, the fusion was apparently short, though nine of the patients were definitely cured, and are so classified. Two of the nine were explored and the fusion found complete. One of the fifteen died of miliary tuberculosis. Three others were reoperated on, the fusion was extended and the symptoms subsided. The patients are classified as cured. The other two had disease of the laminae. The disease is probably still active and the cases are classified as doubtful. Nine patients showed a slight increase in deformity, although fusion was apparently complete. They are well and in school and classified as cured.

In twelve of the thirty-six patients, there was a marked increase in deformity. In eight the fusion was too short and in four there was a pseudarthrosis. Of these patients in whom the fusion was too short, five were reoperated on, and there has been no increase since. Of the remaining three, one is in bad shape and refuses reoperation. The other two were taken from the operating table without completion of the operative work. Both died later of miliary tuberculosis. In the four cases of pseudarthrosis, three of the patients were reoperated on and cured. The fourth was reoperated on but died later of amyloidosis.

A study of the region involved in these cases shows that nineteen were in the dorsal region, ten cases in the dorsolumbar, and three in the lumbar. Of the dorsolumbar cases three included involvement of the two lumbar vertebrae. The remaining seven included only the first. Two of the pseudarthroses were in the dorsal and two in the dorsolumbar. Those in the dorsolumbar region included involvement only of the first lumbar.

Eighty-three per cent. of the 210 cases showed less deformity or no increase.

Seventeen per cent. of the 210 showed an increase of deformity. Fifteen per cent. of these had fused areas that were too short and in 2 per cent. there was a failure of fusion at one point as evidenced by pseudarthrosis.

Results of Fusion Operation Where Duration of Disease Was Less Than Six Months.—It must be considered here, as in all the cases, that the parent's history as to duration is not entirely reliable. There were seventeen cases. Thirteen patients are now in excellent condition although two had to be reoperated on for a short fusion. One was in excellent condition before he died of pneumonia. One we are unable to trace but was in fair condition when last seen. One is dead of miliary tuberculosis. One now has definite sacral disease. This gives a percentage of 82 cures as compared with the general average percentage of 75. It will be noted that eight of these seventeen patients had symptoms of cord pressure. All were cured. It is also interesting to note that one patient had a vertebral involvement of four. Eight cases had three, and eight had two vertebrae involved.

Patients in Very Poor Condition Before Operation.—In the 210 cases there were eighty-seven in poor condition before operation. Fifty-three of these are now in good condition and considered cured. Twenty are dead, two from pneumonia, both of whom were in good condition before death. Six have been lost track of. Two had pulmonary tuberculosis before operation and the disease is still active. Two are not in very good condition although one has apparently a perfect fusion and the other has a fusion that is short. One patient is still paralyzed but is in good condition. He is not considered cured. One has hip disease, and while the Pott's disease is apparently cured, it is not so considered. One has active disease of the sacrum and is counted among those not cured. The last one has heart disease, having been cured of Pott's disease.

Miscellaneous.—There were five patients with disease of the spinous processes and laminae. Two of these patients were affected in the dorsolumbar region. One of them is dead of miliary tuberculosis, with incomplete fusion, and the other is in good shape and has a perfect fusion. The other three patients were affected in the dorsal region. One patient is in fairly good condition with complete fusion. Another shows increased deformity and is not improved. The third has a short fusion. Only two of the patients are considered cured.

It is interesting to note here that disease of the spinous processes and laminae does not always prevent their fusion.

Patients Who Had Bone Graft.—Three patients in the series had had previous bone graft operations at other hospitals, one of which was done in the dorsal region, and the other two in the dorsolumbar. There was no fusion in any case, and all the patients had symptoms of active disease, one with six discharging sinuses from two psoas abscesses. In two cases, there was only a small piece of bone of the graft remaining in one spinous process. In one case there was a thin piece of continuous bone in the tips of three spinous processes. Perfect fusion was obtained in all three cases and the patients are among the cured.

The average age of patients of the whole group at the date of operation was 8.9 years. The average duration of disease before operation was 4.4 years.

CONCLUSION

This study gives convincing evidence that by this operation a fusion of the vertebrae may be obtained in every case in which a careful dissection is made, as in only four cases has fusion failed to take place at one point in the operated area, and in these it was undoubtedly due to imperfect operative technic. It seems equally convincing that the effect of fusion on these cases has been to hasten the cure of the dis-case and to limit the progress of the deformity. If this can be accomplished in a series of patients who had had the disease for an average of 4.4 years at the time of operation, is it not fair to conclude that had they been operated on earlier in the disease their cures would have been quicker and the deformity less, and does it not suggest that all cases of vertebral tuberculosis in any region of the spine should have a fusion operation at the earliest possible moment?

ABSTRACT OF DISCUSSION

Dr. Charles M. Jacobs, Chicago: I have operated in only two cases of tuberculous spine disease by what I believed to be the Hibbs method. It then occurred to me that either there was something radically wrong with the method or with my technic. I went to New York, unfortunately finding Dr. Hibbs suffering from an attack of lumbago, and therefore was unable to see him operate. His assistant told me that to get an accurate idea of the technic of this operation it is necessary to see Dr. Hibbs operate, as there is as much difference between his "description of the operation and his technic as there is between darkness and daylight." Probably this is the reason why the Hibbs operation is not performed more often.

My surgical experience in tuberculous spine disease is based on the bone transplantation method. There can be no doubt that surgical measures for tuberculous spine disease are a great advance over conservative treatment, but they should be restricted to selected cases. Undoubtedly they shorten the period of disability. My own private patients seldom are operated on, because I believe that in children the length of time necessary to a cure plays no important part. If, however, treatment must be carried on beyond the average time, which is about four years, or if deformity continues to increase, then I advise operative procedure. My clinical patients are practically all subjected to operation, because they must regain health in the shortest possible time; therefore, conservative treatment in their case demands a sacrifice justified only by a necessity which I consider no longer exists.

In Dr. Hibbs' series of 210 cases taken from the New York Orthopedic Hospital and Dispensary, which, of course, are the poor class of patients, 157 patients were cured; in thirty-five cases there was paralysis and in a certain number cold abscesses occurred. Following his operation he stated that a brace was applied. I did not hear him state in what period of time a cure occurred, or how long the brace was applied.

I should like to ask Dr. Hibbs whether he operates in all cases of tuberculous spines—on private as well as dispensary patients—also, what effect his operation has on paralysis and abscesses. We know that children who are suffering from Pott's paraplegia usually get well on a Bradford frame without operation in an average period of one year.

Dr. Willis C. Campbell, Memphis, Tenn.: I have done only two of these operations. The trouble is in not seeing the operation after reading the description. It really is a difficult procedure, and one in which it is necessary to see the actual work before you can thoroughly understand it. One of my patients was a very poor risk, being quite old, and after operation I learned that he was a morphin habitué. He died of sepsis, of course, through no fault of the operation. In the other case, the laminae were diseased, also the spinous processes. In that case I obtained a good result. A plaster cast was applied and was worn six months. The patient has been without it now for over a year, without recurrence of symptoms. Of course, I do not class that patient as cured, because there has not been sufficient time.

There are five points of fusion in the Hibbs operation. I have often heard it said that the spinous processes will not unite; but even if they do not, there are the laminae on both sides, making two other points, and the articular processes, so that we have a chance of fusion at five points, with little chance of failure, if the work is done accurately.

Dr. Fred J. Gaenslen, Milwaukee: Dr. Hibbs mentioned that in a number of his cases the lessening of the deformity was greater than he could account for by the deflection of the posterior spinous process. I should like to know whether he thinks that growth was responsible for this improved appearance.

Dr. Henry B. Thomas, Chicago: I have had a number of tuberculous spine cases in which I have operated according to the Hibbs method, guided by what Hibbs had written. I did not know his method thoroughly until I actually watched him operate. Now, after I have carefully studied nature's cure of tuberculous spines when not aided by operation, and seen in the skeleton how ankylosis probably began first around the laminae and the bases and tips of the spinous processes, and last about the necrotic bodies, I am convinced that what Dr. Hibbs does in his operation, in twenty or thirty minutes, is to prepare the field, the normal neighboring bone, for ankylosis, exactly as nature prepares it after the bodies of the vertebrae have given way so much by the decay as to allow the posterior parts of the spinal column to drop down so that they can rub off their periosteum and prepare for ankylosis. This is the beginning of fixation. Hibbs advocates a preparation in a few minutes' time which nature would require a year or so to complete. There is no doubt the first ankylosis which takes place is between good bone around the laminae posterior processes and in the articular processes. After nature gets that fixation by means of the good bone and removes the debris from the decayed bodies, these then, after a year or two, ankylose. In my judgment, if we have an operable case of Pott's disease, the Hibbs method is preferred.

Dr. Russell A. Hibbs, New York: In the first place, as to the question of whether the advice that I have given to the hospital patients applies to my private patients, let me say with all the emphasis possible, Yes. I have not a single private case of Pott's disease under my care today that has not been operated on in this way, and I do not want one. As to the effect of the operation on paralysis, of course, the operation, as such, has no effect on paralysis. The only effect it has is by its curative effect, if it has any, on the active tuberculous disease of the vertebrae. The operation has but one object, and that is the elimination of motion; and if by that it hastens the cure of the disease, it also hastens the cure of the paralysis and every other symptom of the disease; and if it does not hasten that, it does not hasten any of these things.

I have waited this long time before making a report of this work because it takes so long to see the final results, and only by and study of the final results can any fair estimate be made of the value of the operation.

Railroads and Malaria in the South.—R. C. Derivaux, of the United States Public Health Service, in *Public Health Reports,* Aug. 2, 1918, discusses the relation of the railroads in the South to the prevalence of malaria and its control. He shows that the railroads of the South have in many instances not only contributed to the spread of malaria by the promotion of conditions along the right-of-way which have fostered mosquito breeding, but they have also suffered economically from the morbidity from malaria among their employees. Recognizing this fact, many of the railroads have begun efforts to improve conditions in this respect. The St. Louis and South Western Railroad has taken up the matter of malaria prevention, and already has accomplished considerable in this direction. It was found that about 25 per cent. of all admissions to the hospital at Texarkana were for malaria. An average of 640 patients were treated for five days each year during the past four years. This was equivalent to about 4 per cent. of the total number of employees. Efforts at prevention were begun in 1917 at certain points along the line. In 1916, thirty-two malaria patients were admitted to the hospital at Texarkana; in 1917, following malaria work, only thirteen patients were admitted, a reduction of 59.4 per cent. The sale of quinin had decreased about 49 per cent. Among bridge and building gangs, whose bunk cars were screened, a reduction of 47.7 per cent. was obtained in the number of cases of malaria in 1917 over 1916. At one point in a small lumber community where malaria had been severe, after one year of work practically no malaria occurred, and the mill increased its output 20 per cent.

STATE RESPONSIBILITY AND AIMS IN COUNTY HEALTH WORK*

J. N. HURTY, M.D.
INDIANAPOLIS

It is plain that most of the relations and responsibilities of states to counties are very different from the relations and responsibilities of the national government to states. In comparing national and state reciprocal responsibilities, therefore, we shall probably not find any facts or considerations to aid us. As counties are decreed, defined and empowered by states, we perforce recognize that state responsibilities are fundamental, and aims must be on high levels, not only in the matter of health, but in all ways.

Under our democratic form of government, the state should have a wise general health law, clearly prescribing duties and powers that counties should have for doing successful public health work. But the utmost possible freedom should be accorded to enable the inhabitants of counties to work out their own salvation according to their abilities. It would be necessary, for a state health law to secure live, progressive counties against the stupidity, blunders or inaction of those that might be slow or retrogressive. In other words, state responsibility requires that, under carefully defined conditions, the central power may proclaim for a county what is reasonable and necessary to protect the reasonable rights of other counties. All of this would truly be making democracy safe for the world, which is the first step in making the world safe for democracy. I believe the North Carolina health law very fully recognizes these principles, and under the present direction is achieving excellent results.

As speeding up is sometimes not only desirable but also necessary, I would consider it a responsibility for most states to command that counties or groups of counties should employ skilled all-time health officers, should follow a uniform outline or procedure in public health work, should give a fair living compensation, and provide a reasonable health fund, leaving open every reasonable opportunity for individual initiative. If these fundamentals are not secured, lopsided work for the whole state area would most probably result, and a state map showing results might be as spotted as a leopard.

It is not enough that, for their health work, counties should be held accountable only to themselves; the state, therefore, should command an accounting because of state responsiblity. This accords with the accepted principle that "No man can live by himself alone." Undoubtedly, very full initiative and freedom should be accorded, but the limitations outlined are responsibilities which states surely carry.

I believe that a state's responsibility extends to providing for sloughing off incompetency in county officialdom, and therefore, if a county does not slough off its incompetent officials, then the state should attend to this important matter, which is essential to all successful government. Again, it is necessary that health officials, as well as all other officials, should keep up with the times. Present day statesmanship, therefore, recognizes as the first requirement of progress a constant reexamination of the entire structure of government to see if its fundamentals are correct and if the various parts are doing the work assigned to them. Perhaps we heard in years past too much of freedom and liberty and independence, and not enough about fulfilment of duty and obligation of service. These momentous days have brought quickly the lessons of mutual dependence, and they must instil the idea of discipline.

Still, that is not enough. To a new degree we must be interested in each other. The parents who raise a family of sturdy defenders of the nation will be assured that other parents are doing as much, so that their own labor will not have been in vain.

These general thoughts have application to a set of facts brought to light in the public health administration of Ohio outside of the larger cities. The state health authorities say it is almost worse than nothing in rural districts, and the same authorities of Indiana have testified to almost like effect as to the same conditions in that state.

This is a new offense to be charged to the rural districts whose representatives are constantly ready to represent the cities as centers of evil. Perils of typhoid and other infections, perils of child neglect and of blighting disease, certainly come in no small degree from the country to the city. Here is a state responsibility in county health work. The larger cities are keenly interested in their health departments and in having trained health officials, and city people now loudly demand the ministrations of hygiene. On the other hand, it has been shown that the administrative health positions in the county areas go to those who have done political work or who are appointed because of political affiliations. It is plain that the larger cities with lower morbidity and mortality rates and better care of infants and children will not long submit to surrounding unhygienic conditions.

A method of this character cannot endure, and the wildest dream of liberty would not wish its continuance. Rural domination over cities has long been submitted to, but now things have come to such a pass that for self-protection in health affairs, cities will have an interest in and insist on better rural hygiene. Likewise, it is time to do away with a system that does harm to both city and country.

If counties will not, after instruction, do that which is necessary for their own and their neighbors' health and comfort, then it will be the state's *responsibility* to take up the work.

As to state aims in county health work, it has already been said that aims must be high and noble. The first principle is that the people must secure better health and still better health, mostly through individual hygiene. The submerged, the almost submerged, and those whose heads just protrude above the flood of incompetence and ignorance, *must* be forced to be virtuous and to keep in the narrow path of health. Those who are only waist deep in the same flood may be instructed and led, and those who ride on the flood will be doers, instructors and leaders. The strong man does not need looking after, for he looks after himself and others. At the same time the strong man is to blame for the ills of society, for he is the only hope for their prevention. And let us note here that custodial care of the victims of the neglect of hygiene will not make health for a people. The state aims in county health work are the same as for everywhere else, namely, to cease the fostering of the production of low-grade nonresisting stock, for the individuals of such stock cannot learn and will not conform to the laws of their well being.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

ABSTRACT OF DISCUSSION

Captain Réné Sand, Belgium: One of the principal effects of the war is to have demonstrated to the authorities and to the nation at large how desirable, useful and even indispensable public health work is. Of course, I consider the problem differently from what you do because you have immediate necessities and we, in Belgium, look forward only to the situation as it will be after the war. Therefore our views are necessarily more general. After the war we will have to enlist in the public health service every physician of the country. I do not know, of course, exactly what the situation is here, but I think that finally if you consider every phase of the problem the best way to have good health service, to have hygiene entering into every household, would be to make every doctor in the country, at least every doctor who is willing to do so, an agent of the public health service and to give him some remuneration for his services. We see in our country, and it is the same in France and other continental countries, a certain amount I would not say of diffidence, but nevertheless the public health service goes along more or less indifferently with the general practitioner, while if you would put the general practitioner in direct touch with the public health service, give him a great amount of information, call him to meetings with the public health officials and give him a scientific, a civic and also a pecuniary interest in the work, I think you would have a much greater spreading effect than by many other methods. In some of your states you have a sort of house to house visit in order to convince the citizens of the necessity of improving the health of their dwellings and their general habits. Who can do that better than the general practitioner? If you ask him to do that for every one of his patients he will tell you he has not the time to do it, that he must earn his living. If you interest him by giving him some remuneration, then, of course, his argument will fall and he will be your helper. I think the two great defects of actual medical practice are, first, that the practitioner is able in many cases to have the experts at his disposition and, second, that we have not the organization at present on the large scale that it should be.

Mr. F. L. Hoffman, Newark, N. J.: The question which has been raised by Captain Sand of the Belgian Industrial Commission is indeed a most important as well as practical one to the American people at the present time. It is quite probable that one of the unforeseen consequences of the war will be a restored Belgium, in which all matters of health and medical administration will be raised to a standard such as has heretofore been considered unattainable. The new Belgium will be confronted by the imperative necessity for the practically immediate solution of health problems which have given us such serious concern during recent years. New diseases will have been introduced in consequence of the war, not the last and least of which, malaria, may prove a future health problem of sufficient importance to demand the introduction of preventive measures, which have been found so successful in this and other countries where the disease prevails to a more or less serious degree. Belgium before the war had a reasonably satisfactory public health administration, but it is probably a foregone conclusion that with a depleted medical staff and diminished financial resources, a most rigid economy will be necessary in the medical and institutional care of the Belgian people. It is, therefore, quite readily conceivable that some plan of coordinated state health and medical administration may come into existence, under which the large majority of the people will be provided for as regards their medical and surgical needs at minimum expense. In England a similar tendency has developed in consequence of the war and urgent demands are being made for a ministry of health with its functions intelligently coordinated to the needs of the people for adequate and efficient medical and institutional treatment at minimum cost. Such a system of state medicine is, however, a question of taxation and not of insurance. The paramount duty is to eliminate at the outset all unnecessary bureaucratic organizations which have so largely become the means or methods of oppression and ruthless government control in the German empire. First and last, however, the question is one of prevention rather than of treatment and cure. It is to be hoped that Belgium will be the first nation after the war to establish a really efficient state health administration, having for its main purpose the prevention of any and all diseases, as well as physical defects and deformities, which can be dealt with rationally and effectively by the state. It would be a calamity if such a worthy purpose were to be interfered with, or perhaps partially defeated by a continued imitation of the German fallacy of compulsory insurance. The more thoroughly the details of this aspect of the question are inquired into by those qualified to do so, the more convincing the conclusion that the problem is one of efficient administration on the one hand, and of equitable taxation on the other, and neither by direction or indirection one of insurance in the accepted sense of the term.

Dr. James A. Hayne, Columbia, S. C.: In 1878 we endeavored in South Carolina to have the entire medical profession interested in public health work. We created a state board of health and that state board of health is the South Carolina Medical Association. It has about 700 members, practically every worth-while doctor in South Carolina. Our legislators at that time thought that that would certainly interest all the medical profession of the state in public health work, and it not only did that but it read into the constitution of the state these words, that the State Board of Health of South Carolina shall be the sole advisors of the citizens of the state in matters pertaining to health. It put the responsibility where it belongs, on the medical profession, and put the advice-giving authority where it belongs, with the medical profession. Of course, since that time a great many other agencies have sprung up to give advice to the people on public health that are not always confined to the medical profession. Whether they give good advice or not is a matter of a great deal of difference of opinion. In regard to state medicine the only opportunity I ever had to study that was when I was on the Isthmus of Panama where every doctor was employed by the United States government, and he was assigned to a certain district. A certain force was assigned to that district. Any visit made by the doctor was paid for by the United States government. The person he visited, if he was not an employee, signed a receipt for that visit. The money was collected out of that man's salary, and not paid to the physician who made the visit but it was paid back into the engineering fund to help the building of the canal. Now, you may say that the physician did not care whether he visited the patient or not or whether the patient got well or not, because the doctor got nothing more for it if he paid the patient ten visits than if he paid him one, so he would neglect his patients by paying only one visit. There was a check on that, however. Each district had to report to the chief sanitary officer every morning showing the health conditions in that district for the previous twenty-four hours, and if there was an increase of any disease, he was immediately called on the telephone to know why his district had gone above the normal rate. He was told that if he could not correct those conditions to ask for aid from the chief sanitary officer and help would be sent him and in that way the normal of disease or average amount of disease in his district would be kept down.

Results of the Children's Year Program in California.—In the weighing and measuring drive of the Children's Year national program in California, in June and July, between 40,000 and 50,000 record cards were distributed, and to September, 1918, 40,863 of these had been returned to the state chairman of the Children's Year Committee. These report on children of less than 6 years of age and it is said more are to be received. In a tabulated statement in the *California State Journal of Medicine* for September, 1918, Dr. Adelaide Brown, San Francisco, chairman of the committee, shows that of the total number of records received 32,167 have been analyzed. The number of children who had tonsils and adenoids requiring operation was 10,133, or 31 per cent. The total number of defects of all characters was 15,261, or 47 per cent. Of the 29,917 cards tabulated for height and weight, the number of children below normal height and weight was 8,731, or 29 per cent. The total for defective teeth was 1,678, or 6 per cent., of the 27,407 cards analyzed in that study.

Clinical Notes, Suggestions, and New Instruments

THE USE OF OXALATED AND CITRATED BLOOD FOR ROUTINE CLASS STUDY*

Frederick Howard Falls, M.S., M.D., Chicago

The problem of presenting to students various pathologic blood specimens in connection with clinical laboratory work is often one of considerable difficulty. This is especially true of colleges which have a small teaching hospital or none at all, or which are far removed from the large medical centers. Ideally, of course, each student should come in contact with the various diseases studied and observe the blood picture in connection with the other symptoms of the disease. Even in the more fortunately located institutions with attached teaching hospitals, it is sometimes impossible to bring the students in contact with the patients having blood diseases, because of the size of the classes and because of the inconvenience afforded to patients who may be severely sick at the time of the examination.

These objections have been met in the past by obtaining blood smears in the usual way and passing them out stained or unstained to the student, or by means of loan collections owned and cared for by the department. Obviously a complete blood examination including red and white counts and hemoglobin estimation is impossible under these conditions. Besides, the student is deprived of the opportunity to make smears personally, which is an important technical point in routine blood examination.

Failing the ideal bedside study of the blood picture, an approximation may be sought by furnishing the blood to the student for examination in practically the same condition that it exists in the patient so that he can make his various smears and dilutions at some distance from the case. This can be very satisfactorily met by the following simple procedure: A few crystals of sodium citrate or sodium oxalate are placed in a 10 c.c. Lüer syringe, and blood is withdrawn from the median basilic vein in the usual manner. On entering the barrel of the syringe the blood plasma dissolves the citrate, and this effectually prevents the clotting of the blood. The blood is then blown out into sterile tubes and kept in a cool place until ready for use. Blood may be kept for hours by this method without undergoing any appreciable change either in its cell count or in the staining reactions of the individual cells.

The blood is then studied in the routine way that the student has used in the study of normal blood, and such details as concern symptoms, the diagnostic significance of the blood picture or any others which in the opinion of the instructor will add to the value of the exercise are added.

By this method I have studied specimens from cases of pernicious anemia, leukemia, lymphatic and myelogenous, malaria, trichinosis, secondary anemia, and cases with varying grades of leukocytosis.

Red and white counts and hemoglobin estimations have been made both before and after treating the blood with oxalate. Differential counts were made on stained smears from oxalated or citrated blood, and no differences in the staining properties could be detected. One point is to be noted in making red and white counts: On standing even for a few minutes, there is a marked tendency for the corpuscles to settle out of the citrated plasma. If then a blood count pipet is introduced into the tube and blood from the upper layer is taken, the count will be found to be less than that of the uncitrated blood of the same patient. If, on the other hand, the pipet is introduced to the bottom of the tube, the blood count will be found to be above normal. It is necessary, therefore, to shake up the citrated blood thoroughly, immediately before making a red or white blood count, in order to get a uniform admixture of cells and to estimate the true number per cubic millimeter.

It is considered advisable to use the crystals rather than solutions of sodium oxalate or citrate in order to minimize the changes in the quantitative determinations due to dilution of the sample, especially in making the red and white counts.

CONCLUSIONS

1. The use of oxalated or citrated blood for routine class study is practical and desirable.
2. No differences in staining reactions or in making red or white blood counts could be detected when using oxalated or citrated blood as compared with normal fresh blood.
3. These conclusions hold for the pathologic blood studied as well as for normal blood.

A CONVENIENT METHOD FOR FILING SURGICAL SECTIONS*

W. L. Robinson, B.A., M.B., Toronto

We have experienced considerable difficulty in keeping our surgical sections properly filed in such manner that they might at all times be readily accessible, and at the same time have proper notes filed with them which could be indexed and cross-indexed.

The filing of the sections in one set of drawers and the cards, with notes on these sections, in other drawers is not only an inconvenience but also involves unnecessary work. To obviate this we have mounted the section on the back of the filing card, in which a hole has been punched, to enable one to examine the section under the microscope while it is still attached to the card. An ordinary filing card, 4 by 6 inches, is used, and a hole seven-eighths inch in diameter is made with a steel punch in the center of the lower margin. The section is then pasted to the back of the card with cover-slip side toward, and just under, the hole with two short pieces of passe-partout seven-eighths inch wide. This will hold the section firmly to the card, and it can be handled freely without danger of detaching the section.

NAME AGE
SURGEON WARD
CLINICAL HISTORY
GROSS SPECIMEN
MICROSCOPIC REPORT

Filing card with section.

MODE OF PROCEDURE

One of these cards is filled out and the specimen given a serial number just as soon as it is brought to the laboratory. A synopsis of the clinical history is written and a gross description made. When the section is through, the technician pastes it on the back of this card, using blank cards for any extra sections there might be. They are then brought in for histologic description and diagnosis. A complete report is made out from this, in triplicate, by the stenographer. The cards with sections attached are then filed, according to serial number, in ordinary filing cabinets. One copy of the report is then filed alphabetically in our laboratory, with cross-index

ABSTRACT OF DISCUSSION

Captain René Sand, Belgium: One of the principal effects of the war is to have demonstrated to the authorities and to the nation at large how desirable, useful and even indispensable public health work is. Of course, I consider the problem differently from what you do because you have immediate necessities and we, in Belgium, look forward only to the situation as it will be after the war. Therefore our views are necessarily more general. After the war we will have to enlist in the public health service every physician of the country. I do not know, of course, exactly what the situation is here, but I think that finally if you consider every phase of the problem the best way to have good health service, to have hygiene entering into every household, would be to make every doctor in the country, at least every doctor who is willing to do so, an agent of the public health service and to give him some remuneration for his services. We see in our country, and it is the same in France and other continental countries, a certain amount I would not say of diffidence, but nevertheless the public health service goes along more or less indifferently with the general practitioner, while if you would put the general practitioner in direct touch with the public health service, give him a great amount of information, call him to meetings with the public health officials and give him a scientific, a civic and also a pecuniary interest in the work, I think you would have a much greater spreading effect than by many other methods. In some of your states you have a sort of house to house visit in order to convince the citizens of the necessity of improving the health of their dwellings and their general habits. Who can do that better than the general practitioner? If you ask him to do that for every one of his patients he will tell you he has not the time to do it, that he must earn his living. If you interest him by giving him some remuneration, then, of course, his argument will fall and he will be your helper. I think the two great defects of actual medical practice are, first, that the practitioner is able in many cases to have the experts at his disposition and, second, that we have not the organization at present on the large scale that it should be.

Mr. F. L. Hoffman, Newark, N. J.: The question which has been raised by Captain Sand of the Belgian Industrial Commission is indeed a most important as well as practical one to the American people at the present time. It is quite probable that one of the unforeseen consequences of the war will be a restored Belgium, in which all matters of health and medical administration will be raised to a standard such as has heretofore been considered unattainable. The new Belgium will be confronted by the imperative necessity for the practically immediate solution of health problems which have given us such serious concern during recent years. New diseases will have been introduced in consequence of the war, not the last and least of which, malaria, may prove a future health problem of sufficient importance to demand the introduction of preventive measures, which have been found so successful in this and other countries where the disease prevails to a more or less serious degree. Belgium before the war had a reasonably satisfactory public health administration, but it is probably a foregone conclusion that with a depleted medical staff and diminished financial resources, a most rigid economy will be necessary in the medical and institutional care of the Belgian people. It is, therefore, quite readily conceivable that some plan of coordinated state health and medical administration may come into existence, under which the large majority of the people will be provided for as regards their medical and surgical needs at minimum expense. In England a similar tendency has developed in consequence of the war and urgent demands are being made for a ministry of health with its functions intelligently coordinated to the needs of the people for adequate and efficient medical and institutional treatment at minimum cost. Such a system of state medicine is, however, a question of taxation and not of insurance. The paramount duty is to eliminate at the outset all unnecessary bureaucratic organizations which have so largely become the means or methods of oppression and ruthless government control in the German empire. First and last, however, the question is one of prevention rather than of treatment and cure. It is to be hoped that Belgium will be the first nation after the war to establish a really efficient state health administration, having for its main purpose the prevention of any and all diseases, as well as physical defects and deformities, which can be dealt with rationally and effectively by the state. It would be a calamity if such a worthy purpose were to be interfered with, or perhaps partially defeated by a continued imitation of the German fallacy of compulsory insurance. The more thoroughly the details of this aspect of the question are inquired into by those qualified to do so, the more convincing the conclusion that the problem is one of efficient administration on the one hand, and of equitable taxation on the other, and neither by direction or indirection one of insurance in the accepted sense of the term.

Dr. James A. Hayne, Columbia, S. C.: In 1878 we endeavored in South Carolina to have the entire medical profession interested in public health work. We created a state board of health and that state board of health is the South Carolina Medical Association. It has about 700 members, practically every worth-while doctor in South Carolina. Our legislators at that time thought that that would certainly interest all the medical profession of the state in public health work, and it not only did that but it read into the constitution of the state these words, that the State Board of Health of South Carolina shall be the sole advisors of the citizens of the state in matters pertaining to health. It put the responsibility where it belongs, on the medical profession, and put the advice-giving authority where it belongs, with the medical profession. Of course, since that time a great many other agencies have sprung up to give advice to the people on public health that are not always confined to the medical profession. Whether they give good advice or not is a matter of a great deal of difference of opinion. In regard to state medicine the only opportunity I ever had to study that was when I was on the Isthmus of Panama where every doctor was employed by the United States government, and he was assigned to a certain district. A certain force was assigned to that district. Any visit made by the doctor was paid for by the United States government. The person he visited, if he was not an employee, signed a receipt for that visit. The money was collected out of that man's salary, and not paid to the physician who made the visit but it was paid back into the engineering fund to help the building of the canal. Now, you may say that the physician did not care whether he visited the patient or not or whether the patient got well or not, because the doctor got nothing more for it if he paid the patient ten visits than if he paid him one, so he would neglect his patients by paying only one visit. There was a check on that, however. Each district had to report to the chief sanitary officer every morning showing the health conditions in that district for the previous twenty-four hours, and if there was an increase of any disease, he was immediately called on the telephone to know why his district had gone above the normal rate. He was told that if he could not correct those conditions to ask for aid from the chief sanitary officer and help would be sent him and in that way the normal of disease or average amount of disease in his district would be kept down.

Results of the Children's Year Program in California.—In the weighing and measuring drive of the Children's Year national program in California, in June and July, between 40,000 and 50,000 record cards were distributed, and to September, 1918, 40,863 of these had been returned to the state chairman of the *Children's Year* Committee. These report on children of less than 6 years of age and it is said more are to be received. In a tabulated statement in the *California State Journal of Medicine* for September, 1918, Dr. Adelaide Brown, San Francisco, chairman of the committee, shows that of the total number of records received 32,167 have been analyzed. The number of children who had tonsils and adenoids requiring operation was 10,133, or 31 per cent. The total number of defects of all characters was 15,261, or 47 per cent. Of the 29,917 cards tabulated for height and weight, the number of children below normal height and weight was 8,731, or 29 per cent. The total for defective teeth was 1,678, or 6 per cent., of the 27,407 cards analyzed in that study.

Laparotomy was decided on. At 10 p. m. Dr. Joseph W. McGill operated under ether anesthesia. A 4-inch incision was made outside of the right rectus muscle, liver or intestinal injury as well as perirenal trouble being suspected. Free blood, containing many large clots, was present in the abdominal cavity. Examination of the bladder, intestines and liver disclosed nothing. The posterior peritoneum of the right side was raised by the pressure of the blood and was loosely applied to the parietes. In the region of the cecum the posterior peritoneum was bulging over a large hematoma. Above this point there was a tear in the peritoneum.

After palpation of both kidneys, and swabbing out the major portion of the blood from the general abdominal cavity, the peritoneum of the right posterior wall was stitched in place and the abdomen closed, one drain being directed through a stab incision in the right lower quadrant to the retroperitoneal area, and the peritoneum sutured around it. The pelvis also was drained.

After operation the temperature rose slightly, reaching 102.6 on the following day. The urinary findings were still negative. On the sixth day after operation, after both drain tubes had been withdrawn, the pathologic report on the urine indicated some microscopic blood present in the sample. Macroscopic blood was noted the following day. The amount of blood increased daily until, on the tenth day after operation, the urinary specimen showed a large proportion of blood. The blood content then gradually decreased until the specimen was reported as negative on the twenty-second day. Hexamethylenamin was given in 3-grain doses on the first day of urinary signs, and was continued until the report was returned negative. The hematuria was not considered to warrant operation, as it was assumed that the contusion or laceration would heal spontaneously. A subsequent true nephritis was not considered probable in the prognosis.

The child coughed a little on entrance to the hospital, and the suggestion was made that this might be attributed to diaphragmatic irritation. This cough disappeared without special treatment during the stay in the hospital. The child sat up in a chair on the twenty-fourth day; was pushing herself around the ward in a wheel chair on the twenty-sixth day, and was up and around on the twenty-eighth day after operation. Since discharge the child has been doing well and no complications have been reported.

ACUTE POISONING BY FIVE GRAINS OF ACETYLSALICYLIC ACID—"ASPIRIN"

Edmund P. Shelby, M.D., New York
Attending Physician, City Hospital

The following report shows that some persons are peculiarly susceptible to the effect of acetylsalicylic acid—"aspirin":

Miss A., a strong, vigorous woman, aged 32, weighing 140 pounds, consulted me about indefinite pains in the back and chest which followed a slight sore throat. I prescribed aspirin in 5-grain capsules. The first capsule, of the Bayer brand of acetylsalicylic acid, was taken at 12:15. Forty-five minutes later the patient felt an itching of the scalp, swelling of the hands, and white blotches appeared over the face and body. In a few minutes the eyes were swollen and closed and violent irritation of the larynx set in.

I was hastily summoned and found the patient unable to speak and with marked interference with breathing. The face was hardly recognizable, and the obstruction of the larynx was very alarming. The pulse was rapid and the breathing spasmodic. The question of tracheotomy for the relief of the laryngeal obstruction was considered.

Before my arrival the patient had taken half an ounce of Epsom salt. This soon brought on nausea and a small amount of liquid was vomited, after which the patient fainted. On her return to consciousness the rash began to fade, the breathing became less labored, and the swelling of the eyes subsided. By 3 o'clock, two hours and forty minutes from the time she had taken the acetylsalicylic acid, the patient was fairly comfortable, could open her eyes and speak. At that time the temperature was 98.6, respiration 20, pulse 92. A rapid return to normal followed. The next day no ill effects were apparent.

That these symptoms were caused by the acetylsalicylic acid there can be no doubt, as the patient had not partaken of food or of other medicine since the night before. Unusual susceptibility to the action of salicylates has often been noted, but I do not recall a case in which so small a dose has produced such marked symptoms.

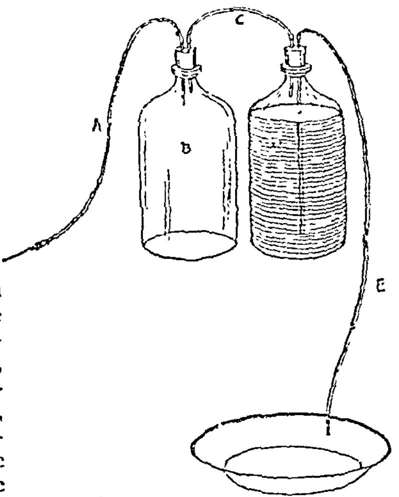
AN ASPIRATOR FOR PARACENTESIS

H. C. Stevens, M.D., Dunning, Ill.

Many forms of apparatus have been devised to create a vacuum sufficient to withdraw fluid from the pleural cavities. The Pétain system is effective when the parts are new. It has the disadvantage characteristic of all complicated mechanisms of easily getting out of order. The two chief difficulties, aside from expense, which we have experienced have been (1) in the valves of the pump, which have failed to close properly, and (2) in leakage about the hard rubber stopper of the bottle. The latter trouble is probably due to changes in the rubber incident to age. To obviate these difficulties, we have devised a simple apparatus which produces suction by means of a siphon. Any hospital possessing two 2-liter bottles, two two-way rubber stoppers, some glass tubing and rubber tubing can assemble an effective aspirator in a very short time. The construction is shown in the drawing. A 2-liter bottle, provided with a two-way rubber stopper, is filled with water and serves as the siphon. In the illustration, *D*, with the tube, *E*, performs this function. A similar bottle, *B*, is sterilized by boiling, together with the tubes *A* and *C*. Bottle *B* is used to collect the effusion. Rubber tubing with an inside diameter of 4 mm. is used. A blunt trocar with a sharp obturator, or a smaller steel needle may be used. A "window" consisting of 2 cm. of glass tubing is inserted into tube *A*, a short distance from the needle. Tube *E* is filled with water and clamped, or allowed to kink from its own weight, at the point where it is connected with the glass tube. If the latter method is followed, simply raising tube *E* will cause the siphon to run; lowering it will stop it. In performing paracentesis, *A*, *B*, *C* and the needle are sterilized by boiling. The siphon is started and then stopped. Puncture is made in the manner, and at the site, preferred by the operator. An assistant starts the siphon as soon as the needle enters the pleural cavity.



Aspirator for paracentesis.

Chicago State Hospital.

The Human Thought Mechanism.—The intellect cannot examine any fact of matter or energy directly. The telephone mechanism of the senses is always in between. Like the line officer in the war, we live in a dugout, the dark dugout of the cranial cavity. Our news comes in over the wires or afferent nerves. Our news is never complete, for our sense organs are not adapted to all the forces of nature. Our news is often faulty because the sense organs or the transmission is imperfect. Often we fail to get messages because our receiving operators are indolent, or doing other things. Moreover, if we get the news straight, we may not use it right; that is, make the right conclusion or judgment.—E. P. Lyon, *Texas State Journal of Medicine*.

Military Medicine and Surgery

MEDICAL STUDIES IN AVIATION*

[NOTE.—This series of papers represents the results of investigations made at the Medical Research Laboratory, Air Service, Mineola, L. I. It concerns particularly the protection of aviators against the effects of high altitudes, low barometric pressure and deficiency of oxygen.—*Ed.*]

I. ORGANIZATION AND OBJECTS OF THE MEDICAL RESEARCH BOARD, AIR SERVICE, U. S. ARMY†

YANDELL HENDERSON, Ph.D. (New Haven, Conn.)
and
E. G. SEIBERT, M.D. (Washington, D. C.)
Lieutenant-Colonel, M. C., N. A.
MINEOLA, L. I., N. Y.

The Medical Research Board was organized early in the autumn of 1917, "to investigate all conditions which affect the efficiency of pilots; to institute and carry out at flying schools or elsewhere such experiments and tests as will determine the ability of pilots to fly in high altitudes; to carry out experiments to provide suitable apparatus for the supply of oxygen to pilots in high altitudes; to act as a standing medical board for the consideration of all matters relating to the physical fitness of pilots." The equipment controlled by the board consists of a large and constantly expanding laboratory for research and teaching at one of the principal eastern flying fields, and of smaller branch laboratories for examining purposes already at work or being organized at twenty other flying fields and ground schools. In the main laboratory, departments have been organized in physiology, cardiovascular functions, psychology, ophthalmology, otology and psychiatry and neurology.

The general purpose of the organization is the study of the effects on the aviator of the peculiar conditions involved in flying. Among these the effect of altitude, that is, of altered barometric pressure, has presented itself as the one of most immediate importance. This series of papers will present a general oversight of the results on altitude thus far accomplished.

In this field four problems demand solution:

1. The cause and nature of the failure, physiologic or psychologic, or both, on the part of the pilot which frequently precedes a fall.
2. The development of a method for determining the maximum altitude to which each individual pilot can ascend without danger of such failure.
3. The development of forms of physical training for increasing the resistance of the pilot to the ill effects of altitude, *and for maintaining* him in a state, not of acclimatization to great altitude like the mountaineer, but rather in the perfect physical condition of the athlete.
4. A deeper knowledge of the nature of air staleness—a condition closely similar to athletic "overtraining," and to the so-called "irritable heart" or neurasthenia of the overstrained soldier.

We are now able to report an approximate solution of the first problem and a complete solution of the second. The third and fourth remain for further investigation from the starting point defined by these studies.

The results of previous investigations, from those of Paul Bert down to those of the Pike's Peak Expedition, had demonstrated clearly that the essential element in the effects of low barometric pressure, that is, great altitudes, on men consists in the reduced partial pressure of oxygen. Mountain sickness had been shown to be fundamentally due, not to the merely mechanical effects of decreased air pressure in the ears and on the blood vessels, but to oxygen deficiency. It was a fair presumption, therefore, from which to start investigation that the same thing would hold true in general of the functional disturbances of the aviator, although some modification of the symptoms might arise from the differences between mountaineering and aviation. These differences evidently consist in the aviator's more rapid ascent and descent, in the greater altitudes reached, and in the briefer period for which he remains at the altitude.

Previous investigations, notably those of the Pike's Peak Expedition, were directed largely to discovering the nature of acclimatization to altitudes. The length of time during which the aviator remains at altitudes is, however, too brief for any appreciable degree of acclimatization to be developed. On the contrary, day by day the brief but repeated strain of oxygen deficiency—a strain much like that of athletic overexertion—produces a cumulative ill effect on the aviator of the higher levels, until, if his condition is not recognized and his flying stopped, he one day loses consciousness at a great height, and falls. For the aviator is essentially an unacclimatized man, and must depend on the capacities of the healthy body adjusted only to the level of his hangar and his quarters. Our investigations have dealt, therefore, not with acclimatization, but with a hitherto largely neglected problem, namely, the organism's immediate compensatory reactions to oxygen deficiency.

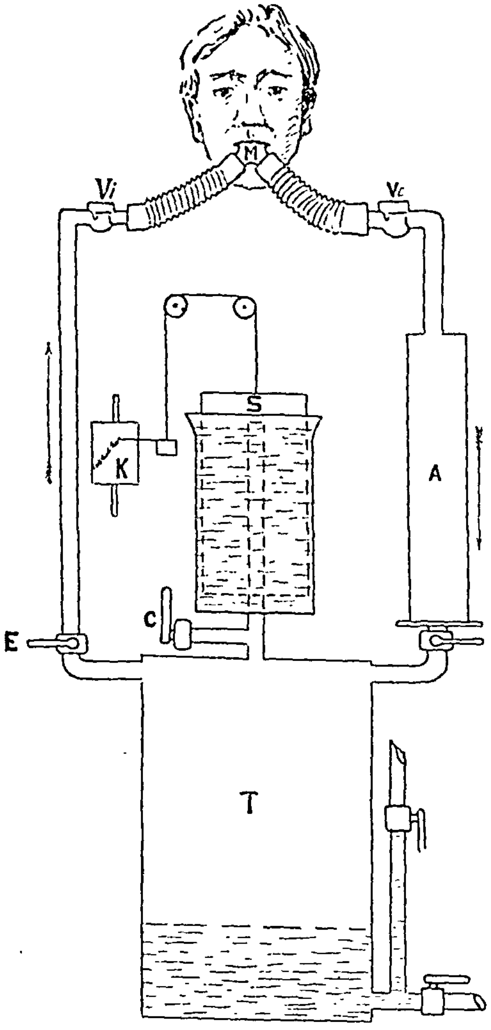
In another class of accidents and near-accidents, the pilot's failure occurs near the end of a rapid descent. Often he has no recollection of how the crash occurred; he had lost consciousness, was asleep. This is highly significant; for this is a state which is induced by an ample supply of oxygen, or fresh air at full pressure, after a period of deprivation. As yet undescribed in the literature, so far as we are aware, and largely unexplained, this interval of unconsciousness, or collapse, or sometimes of excitement and loss of balance physical and mental of alcoholic type, is nevertheless a phenomenon often met by students of the low oxygen problem. It occurs in a wide variety of conditions: in miners escaping from "after-damp," in city firemen after coming out of smoke, in the older types of submarines on opening the hatches after submergence, in persons who are given oxygen after overexertion on a mountain, and after low oxygen experiments in the laboratory. But in none of these conditions are the consequences so serious as for the aviator, when, after remaining for a time at a height greater than he can safely withstand, he makes a rapid descent to denser air. Then, just as he is about to land and needs all his faculties at their best, he develops this oxygen intoxication as the rebound from oxygen deficiency.

---

* Edited by Yandell Henderson, chairman, Medical Research Board.

† From the Medical Research Laboratory, Air Service, Mineola, L. I.

Laboratory experience had shown that to produce the acute effects of oxygen deficiency it is not necessary to climb a mountain or to go up in a plane, or even to be exposed to low barometric pressure. The result is easily accomplished at sea level by breathing into an apparatus consisting of a spirometer and a canister containing alkali. The exhaled carbon dioxid is absorbed by the alkali, while the oxygen is gradually reduced by the continual rebreathing. An apparatus of this sort, the so-called rebreathing apparatus, has been in use for some years past in the physiologic laboratory at the Yale Medical School as a simple and ready method of studying what are virtually the effects of altitude.



The rebreathing apparatus employed in all routine tests of the aviator's ability to withstand low oxygen. It consists of a tank, *T*, of about 120 liters capacity. The volume of air is determined by the amount of water that is run into it. The man under examination continually rebreathes the air of the tank (a clip is placed on his nose) through the inspiratory and expiratory valves, *Vi* and *Ve*. The oxygen is thus consumed and reduced. The exhaled carbon dioxid is taken up by sodium hydroxid in the absorber, *A*. The movements of respiration are recorded by the spirometer, *S*, connected to a smoked drum, *K*. As the oxygen is consumed and the air volume is thus reduced, the spirometer falls and the graphic record on the smoked drum rises. At the end of the test a sample of air is drawn from the tank and analyzed as a confirmation of the oxygen consumption and of the oxygen percentages (that is, altitudes) indicated by the graphic record.

Accordingly, as a preliminary to our work, the first step taken by the physiologic division was to perfect the rebreathing apparatus for routine use. Then followed several months of investigation to determine which of the autonomic functions of the body, e. g., the pulse and the arterial pressure, are most affected by low oxygen. Simultaneously the psychologic and ophthalmologic divisions perfected the apparatus and technic for observation, measurement, and record of motor and sensory disturbances.

Later, a steel chamber large enough to hold six or eight men at once and an air pump were installed, so that observations could be made under any desired reduction of air pressure. The effects observed at pressures equivalent to those attained in actual flying are described in the papers that follow. One experiment, however, deserves mention here. Two men were exposed to a minimum pressure equivalent to an altitude of 35,000 feet (barometer, 180 mm. of mercury). They were supplied with an oxygen apparatus, for air of this tenuity is incompatible with consciousness or even life, and they experienced no ill effects. In a word, these and similar observations have demonstrated that (1) the effects of altitude and low barometric pressure arise from deficiency of oxygen, and (2) in all essential features the conditions obtained by means of the rebreathing apparatus are the physiologic equivalents of low pressure.

It had come to be a generally accepted doctrine that deficiency of oxygen for short periods of time and above a certain limit, say 13 or 14 per cent. of an atmosphere, induces practically no recognizable effects. The subject of an experiment in which the oxygen is progressively reduced is frequently entirely unaware of any alteration in his own condition down to the point at which consciousness is abolished. Even after restoration he often refuses to believe that he has been through the glassy-eyed and wholly irresponsive condition from which the observer has revived him with fresh air.

Nevertheless, so far from moderate deficiency of oxygen being without effect, our observations have revealed the fact that in normal men characteristic alterations of function begin even with a slight lowering of the oxygen tension. Thus it appears that in flying the normal person begins to react almost from the moment that he leaves the ground. These reactions are found to be of a compensatory nature: the resistance of the healthy subject, the fact that up to a certain altitude he feels and shows no immediate ill effects, depends on the ability of his body automatically to effect alterations of breathing, pulse, and psychologic forces such that the net result is a practically normal individual. For all persons there are limits beyond which the body cannot compensate. In this respect there are the widest individual variations, forming a scale from the man with a "weak heart," who can withstand scarcely any reduction of oxygen, up to the man whose respiration and circulation are of such adaptability and power that he can go to 25,000 feet, and yet for a time be virtually normal.

The strain imposed by altitude is closely similar to that induced by extreme physical exertion. In both conditions, oxygen deficiency occurs; but at altitudes and in an aeroplane the effects are the more subtle and dangerous because of the lack of the stimulation to breathing and other functions that the increased carbon dioxid production affords during muscular exertion. For the same reason low oxygen, used with discretion in the low pressure chamber or the rebreathing apparatus, affords a condition clear and simple above any of the conventional forms of physical exercise sometimes employed in internal medicine as aids to examination of the heart.

The resistance and compensatory power of the normal man against low oxygen have been found to be practically the same qualities as "condition" or "training" in the athlete; and lack of compensatory power equivalent to being "out of training." In its more extreme forms it is identical with a "weak heart." From this it follows in theory, as the cardiovascular division in the Research Laboratory has in fact discovered, that the methods based on the rebreathing apparatus are not only applicable for measuring "fitness" and "staleness" in the aviator, but also offer hope for development into that long sought and greatly needed aid to cardiovascular diagnosis: a general test and measure of the "functional power of the heart."

It will be evident, however, that by the expression "functional power of the heart" we mean much more than merely the strength of that organ. We mean, rather, the totality of the processes of the body's gaseous exchanges with its atmospheric environment. These processes are the very essence of life. Low oxygen tests are thus fundamentally measurements of vitality.

In the following papers is contained a general description and a proximate analysis of the compensatory reactions and the forms of overstrain occurring under brief periods of partial oxygen deficiency in men who, having passed the ordinary medical examination, would generally be considered as normal. Among them our methods have revealed a considerable percentage unsuited to fly except at very moderate altitudes, and some unfit to fly at all. It is our hope that the institution of routine examinations by this technic will result in greatly reducing the number of pilots who may lose consciousness in the air and fall, whether because of inherent unfitness or because of otherwise unrecognized air staleness.

During the inception of our work and while our laboratory was being erected, we were allowed the privilege of laboratory space and facilities in the War Gas Experimental Laboratory, then under the U. S. Bureau of Mines. In this and in other matters this bureau has rendered us invaluable assistance. On behalf of the Medical Research Board it is a pleasant duty to express to Director Van H. Manning an acknowledgment of our debt.

New Sources of Quinin.—The extensive antimalarial campaign in India and the increased demand for the drug on account of the war have emphasized the necessity for finding new sources of quinin to keep up the world's supply. The *Indian Medical Gazette* for July describes the situation with reference to quinin in India. There are in that country a number of cinchona plantations in certain districts, under government supervision, which supply a considerable amount of quinin for the use of the government where quinin is a government monopoly. That country, however, like the rest of the world, is dependent for the greater portion of its quinin supply on Dutch Java, where quinin is also a government monopoly. The first plantations were started in India about 1864. On account of the largely increased demand for the drug, in 1900 a new plantation was begun containing about 9,000 acres. This now supplies bark for one of the large factories in India. In the past year the government, with the idea of still further increasing the cultivation of cinchona bark, directed a survey throughout India and Burma to locate cinchona plantations on a large scale. An area which seems to be suitable has been found near the Siam frontier covering about 400 square miles much of which, it is expected, will prove suitable for the successful growth of cinchona trees. The work of clearing and planting this territory will be begun as soon as possible.

II. PHYSIOLOGIC OBSERVATIONS AND METHODS *

EDWARD C. SCHNEIDER, Ph.D.
(Colorado Springs, Colo.)
Major, S. C., N. A.
MINEOLA, L. I., N. Y.

In the Medical Research Laboratory of the Air Service the ability of the aviator to respond to a decreasing oxygen supply is tested by an experiment of from twenty-five to thirty minutes' duration with the Henderson rebreathing apparatus. As the oxygen in the air inhaled from the apparatus is reduced, the man is thereby virtually elevated to a corresponding altitude.

During the test, the rate and volume per minute of respiration, the pulse frequency, and the systolic and diastolic arterial pressures are studied and have been found to give valuable evidence as to the altitude at which the man first responds to oxygen deficiency and as to the efficacy of his compensatory reactions. These reactions consist chiefly in an increased ventilation of the lungs and a more rapid blood flow. In a few men a concentration of the blood also occurs.

Some men compensate so easily and so well that they endure, at least for brief periods, as low as 6 per cent. of oxygen, corresponding to 31,000 feet: an altitude greater than any heavier than air machine has yet reached. Others fail to compensate, or compensate inadequately, and therefore cannot endure even the slight oxygen deficiency of moderate altitudes. From the data obtained in the test on the rebreathing apparatus, it becomes possible to determine approximately the maximum altitude to which the aviator may safely ascend.

If the man is even slightly below the best of physical condition, the altitude to which he is safe is distinctly reduced. A cold, indigestion, late hours, or worry may reduce his resistance temporarily by many thousand feet. More serious indisposition affects him to a corresponding extent.

THE BREATHING UNDER PROGRESSIVE DECREASE OF OXYGEN

The character of the breathing is important. In shallow breathing, only a comparatively small amount of the fresh air gets past the so-called dead space—the nose, pharynx, trachea and bronchi—to mingle with the air in contact with the blood vessels of the lungs. The deeper the breathing the greater will be the amount of fresh air that reaches the alveoli of the lungs, and hence the greater will be the supply of oxygen for the body tissues.

As the percentage of oxygen gradually decreases during a rebreathing test, there occurs a marked respiratory response. In a few men this increase in the lung ventilation begins with the first decrease in the oxygen percentage of the air breathed, and is a gradual proportional increase in inverse ration with the reduction in oxygen. More than 50 per cent. of the men examined, however, gave the first respiratory response between 16 and 14 per cent. of oxygen. Twenty-five per cent. responded first at a lower oxygen tension, while a small number gave no response. The increase in lung ventilation is for the higher percentages only slight, but it usually becomes more pronounced when the available oxygen has been decreased to between 12.5 and 9 per cent.

---

* From the Medical Research Laboratory, Air Service, Mineola, L. I.

The rate of breathing for many men remains unchanged throughout the rebreathing test. The majority, however, show an increase of from two to four breaths per minute at between 8 and 6 per cent. of oxygen. A few of the men examined, showed by other tests to be physically somewhat stale, increased the frequency of breathing enormously.

The increase of volume per minute in the breathing during a rebreathing test differs with individuals. At percentages of oxygen between 8 and 6, the majority show an increase of 5.5 liters over the volume breathed at the beginning of the experiment, when on the average it is about 8.5 liters per minute. This increase gives for the average man a total volume of breathing per minute of approximately 14 liters at oxygen tensions corresponding to an altitude of 25,000 feet. The total per minute volume of air breathed has, in exceptional cases, been as great as 26 and 37 liters of air at oxygen tensions corresponding to from 25,000 to 28,000 feet.

It is the depth of breathing that ordinarily is increased by low oxygen The vast majority of subjects show an increase in depth of breathing of from 20 to 128 per cent. when under from 8.5 to 6 per cent. of oxygen. The volume of each breath in these men is found to range between 600 and 1,250 c.c., while for the same subjects when breathing air of normal oxygen content it is between 360 and 630 c.c.

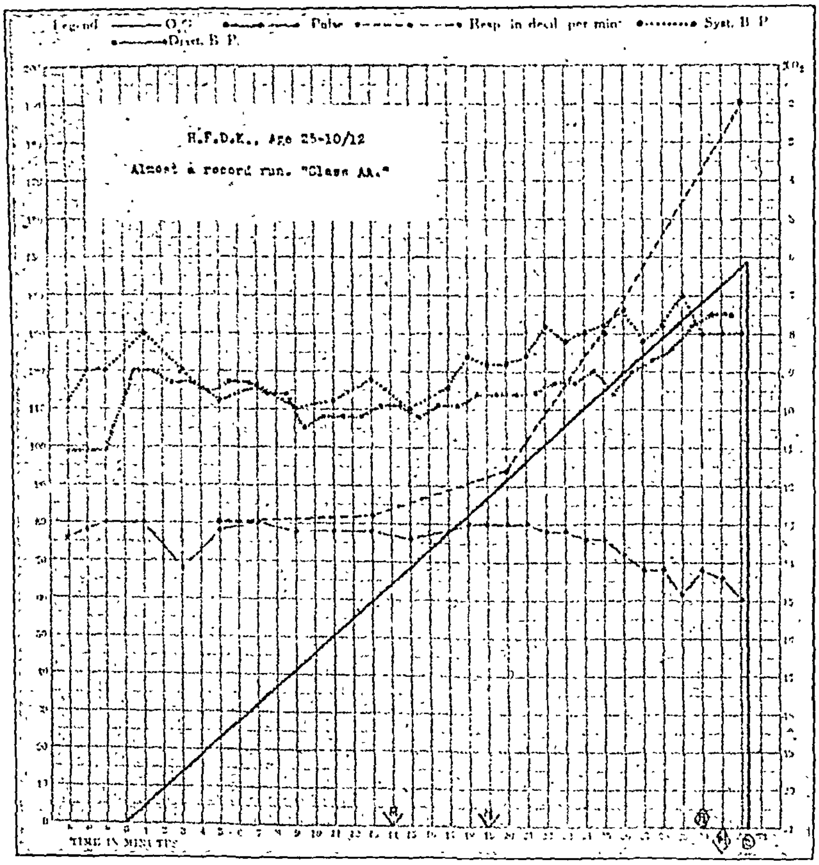


Chart 1.—Results obtained in the examination of an extra good man. The symbols at the bottom of the chart indicate his psychologic condition.

A good respiratory reaction to the gradual decrease in the oxygen of a rebreathing test is manifest in a slight increase in the depth of breathing, which begins at 16 or 15 per cent. of oxygen and continues progressively to increase slightly and gradually until from 12.5 to 9 per cent. of oxygen is reached. From these percentages down to 8.5 and 6 per cent. of oxygen, the total volume per minute of breathing increases much more rapidly; and the frequency of breathing may also increase from two to five breaths per minute. A total per minute increase of at least 5.5 liters should occur at the lower percentages of oxygen.

When the volume per minute of the breathing fails to increase as the amount of oxygen inhaled decreases, or when it increases only slightly, 1 or 2 liters, the lung ventilation is insufficient, and the subject is found unable to tolerate as low a tension of oxygen as the man whose breathing gradually deepens as the available oxygen decreases. Only a few men have failed to show a respiratory response to low oxygen, and none of these have tolerated well even such oxygen tensions as from 10 to 9 per cent. An occasional subject has been examined whose breathing responded well at first, but who later, when the percentage of oxygen was low, suddenly began to breathe less. When this happened, fainting or unconsciousness quickly followed.

THE HEART RATE UNDER DECREASING OXYGEN SUPPLY

In the active tissues the oxygen tension is always low. The higher the oxygen pressure in the blood, the greater therefore will be the amount of oxygen passing from the blood of the capillaries into the tissues. The dissociation of oxygen from the hemoglobin occurs with great rapidity and is most rapid when the differences in pressure are greatest. (This is not dependent on blood pressure.) It follows, therefore, that when the blood flows more rapidly through the capillaries of a tissue, more oxygen will be made available than if it flows slowly. At high altitudes, or under low oxygen, the blood, at first at least, is less saturated with oxygen than at low altitudes. Therefore, if the blood contains less oxygen, an increase in the rate of blood flow through the capillaries would be a means of providing the tissues with the oxygen demanded for their activity.

An increased rate of the blood flow has been demonstrated in men living at high altitudes and is, undoubtedly, one of the first of the adaptive or compensatory changes occurring in the rapid ascents made by the aviator.

Circulatory observations made on Pike's Peak (14,110 feet) indicate that the increase in the rate of blood flow is largely the result of a greater frequency of heart beat. A study of the pulse rate during exposure to low oxygen should, therefore, give a definite indication of the sensitiveness of the organism. We have found the pulse rate to be a trustworthy indicator of oxygen want, provided care is taken at the beginning of a rebreathing experiment to have the subject calm and quiet.

Throughout the rebreathing test the candidate's pulse rate is counted and the systolic and diastolic blood pressures are determined. The rate of heart beat has been found to accelerate in a few men at 17.5 per cent. of oxygen (5,000 feet). In one group of seventy men the accelerations began as follows:

Between 7,000 and 8,000 feet—from 16 to 15.5 per cent. of oxygen—1 per cent. began to react.

Between 8,000 and 9,000 feet—from 15.5 to 14.9 per cent. of oxygen—12 per cent.

Between 9,000 and 10,000 feet—from 14.9 to 14.2 per cent. of oxygen—20.

Between 10,000 and 11,000 feet—from 14.2 to 13.7 per cent. of oxygen—14.

Between 11,000 and 12,000 feet—from 13.7 to 13.2 per cent. of oxygen—23.

Between 12,000 and 13,000 feet—from 13.2 to 12.7 per cent. of oxygen—20.

Between 13,000 and 14,000 feet—from 12.7 to 12.2 per cent. of oxygen—6.

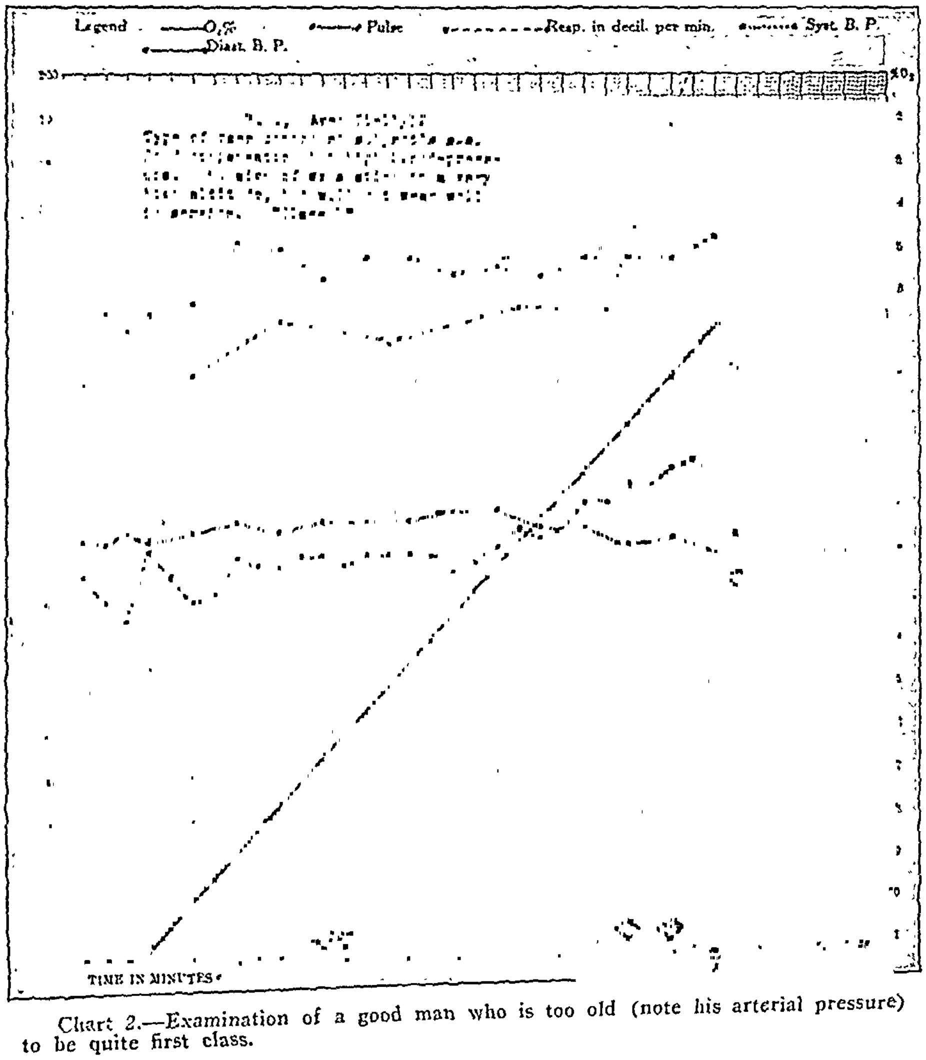

Chart 2.—Examination of a good man who is too old (note his arterial pressure) to be quite first class.

The increase in frequency of heart beat is at first slight, only from one to three beats; but as the oxygen percentage decreases, a greater increase in rate is likely to occur with each decrement in oxygen. A very marked acceleration usually occurs when the oxygen has fallen to between 13 and 9 per cent. Some men at first react with a good acceleration in rate, but soon reach a rate beyond which there is no further response, even though the oxygen percentage continues to be lowered. In such cases after holding at a fixed rate for a while the heart suddenly begins to slow: a sure indication that the limit of endurance has been reached.

A total increase of from fifteen to forty beats in the heart rate during a rebreathing test, in which the oxygen is lowered in half an hour to between 7.5 and 6.5 per cent., constitutes a good reaction to oxygen want. A failure to respond by an acceleration of the heart rate to lowered oxygen means either inability to react to a low oxygen of high altitudes and early failure, or that sufficient compensation is secured by increased breathing or blood concentration or both. Our experience indicates that the failure to respond is associated with poor toleration of low oxygen. An acceleration in heart rate of more than forty beats—from 50 to 70 have been observed—throws too great a burden on the circulatory mechanism, and occurs only in men who do not tolerate well low percentages of oxygen. In such men other compensatory reactions may fail to occur. So far as the response in pulse rate to decreasing oxygen is concerned it therefore becomes possible to rate the reactions poor, good and excessive. A poor or an excessive heart response should disqualify the candidate for very high altitudes; he should ascend to only moderate heights.

A delay in the first appearance of acceleration of the heart rate may be due to an insensitive cardiac brain center, while an early response may indicate a mechanism very sensitive and responsive to any decrease in available oxygen. It should be borne in mind, however, that while ordinarily there is an early acceleration in the heart rate, a delay may be due to the efficiency of other methods of compensating to the stimulus of oxygen want.

THE ARTERIAL PRESSURES UNDER DECREASING OXYGEN SUPPLY

The determinations of systolic and diastolic arterial blood pressures show whether the vasomotor mechanism responds to the stimulus of oxygen want in a manner adequate to maintain the increase in the rate of blood flow. At the same time they show whether the heart is compelled to work against an increased resistance. They also give an index, the pulse pressure, of the volume of ventricular output.

In the optimum type of response to the low oxygen of the rebreathing test the systolic pressure remains unchanged, that is, it holds on a level, until the oxygen has been lowered to between 14 and 9 per cent., after which as the oxygen is further lowered it gradually rises. Occasionally there may occur a gradual rise in the systolic pressure beginning with the first increase in the heart rate. This rise in pressure is ordinarily from 15 to 20 mm. of mercury. Other subjects who appear to have tolerated low oxygen equally well, even down to 6.5 per cent., have had a systolic pressure which held at the normal.

A rise in the systolic pressure of more than 30 mm. of mercury—from 40 to 60 mm. have been observed—is very likely due to a vasomotor failure to respond with a dilatation of the arterioles. Such conditions overwork the heart and may result in early circulatory failure.

There are other conditions of systolic pressure that are occasionally found in men undergoing the rebreathing test. A small percentage have a fall in the systolic pressure which begins about the time the pulse rate starts to accelerate, and continues to decline throughout the test. Such men have not tolerated the extremely low percentages of oxygen that men of the optimum type of response have endured. A large number have shown a sharp and sudden fall in the systolic pressure at low percentages of oxygen. This fall, if allowed to continue, leads to fainting. The subject recovers his normal pressure at once if he is returned to atmospheric air.

The best condition in the response of the diastolic pressure to a decreasing oxygen supply consists in an unchanged or slightly increased pressure throughout the test. Many men show a gradual well controlled fall in the diastolic pressure during the terminal period when the systolic pressure is rising. Such a fall in the diastolic pressure, if it occurs slowly and is not great, constitutes a fairly good reaction to extreme oxygen want. It can be explained as a vasomotor dilatation which occurs in order to protect the heart against the rising systolic pressure. In the optimum type of response to low oxygen the terminal fall in the diastolic pressure may not occur. If present it is never very pronounced and comes only after the oxygen is reduced to 9.5 per cent. or less.

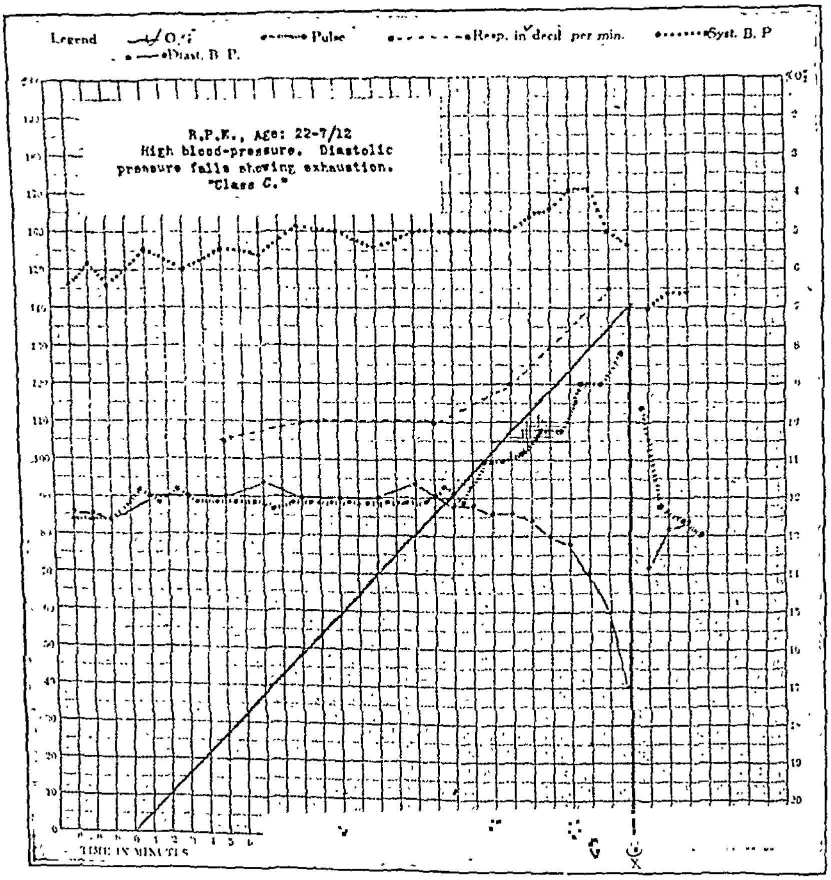

Chart 3.—Examination of a man unfit to ascend above moderate altitudes, unless supplied with oxygen apparatus.

About 66 per cent. of all men examined have had a fall in the diastolic pressure. In at least half of these the fall has been sudden and great. It is always associated with fainting and usually precedes a systolic fall. If the two occur together, in the order just indicated, the experiment must be terminated at once. The pronounced and sudden fall in diastolic pressure may occur at a high oxygen percentage. It has been found to occur as early as 14 and 13 per cent. of oxygen (10,400 and 12,200 feet). Such sudden falls in the diastolic pressure appear to be due to an overcoming of the vasomotor center by oxygen shortage. A decided fall in the diastolic pressure, even if more or less definitely controlled, is an indication that the subject will not tolerate well the altitude corresponding to the oxygen percentage at which it appears.

Three types of circulatory reaction to oxygen want have been observed: The first, the optimum, in which the pulse rate accelerates moderately as the oxygen decreases, the systolic pressure is unchanged or shows a terminal rise of not more than from 20 to 30 mm. of mercury, and the diastolic pressure remains unchanged or rises slightly. The second, the controlled diastolic fall, in which the pulse rate accelerates moderately and the systolic pressure rises as the diastolic pressure gradually falls. The third, the fainting type, in which after a period of fair, good or excessive response in the rate of heart beat to low oxygen, the diastolic pressure suddenly falls, and soon thereafter the systolic pressure, and the pulse rate slows. The optimum type may tolerate as low an oxygen as 6 per cent. (equivalent to an altitude of 29,000 feet) and may lose consciousness without fainting. He recovers quickly when restored to air, while the heart rate and blood pressures are soon back to their normals. The fainting type rarely endures as low an oxygen. If allowed to run his course he faints completely; and as he revives he requires a considerable time, sometimes an hour or two, to regain his normal pulse rate and blood pressures. There are, of course, gradations between the types here described.

The pulse pressure during a rebreathing test remains fairly constant in most men until the oxygen has fallen to between 12 and 9 per cent. (from 14,500 to 22,000 feet), after which it increases in amount during the further reduction in oxygen. The rise in pulse pressure occurs when the systolic pressure is rising and the diastolic either remaining constant or slowly falling. This is also the period when the heart beat is accelerating most rapidly. The amplitude of the heart output, it is claimed, is shown by the pulse pressure. If the pulse pressure be multiplied by the pulse rate and the product be taken as a relative measure of the volume of the blood stream, an increase in the circulation rate will be indicated, beginning between 16 and 14 per cent. of oxygen and progressively increasing as the oxygen further decreases. The period of most rapid flow of blood would, therefore, be that when the pulse pressure is also increasing, that is, from between 12 and 9 per cent. of oxygen to the end of the test. Therefore, a marked increase in the rate of the circulation of the blood during exposure to a low and decreasing oxygen is indicated. This increase in blood flow is, as shown earlier, an important and necessary compensatory reaction to low oxygen.

Incidently a few venous blood pressure determinations made during exposure to a decreasing oxygen supply have shown a fall which becomes very pronounced when the oxygen is 10 per cent. or less. This fall in venous pressure calls to mind a similar fall reported by Schneider and Sisco in men on Pike's Peak and indicates that the reactions observed in the rebreathing tests are the result of the same cause, low oxygen.

THE HEMOGLOBIN UNDER A DECREASING OXYGEN SUPPLY

Since an increase in the percentage of hemoglobin in the blood is one of the most important of the low oxygen compensations found to occur in men and animals living at high altitudes, it is interesting to find that it may also occur during short exposures to low oxygen. The rebreathing test of not more than thirty minutes' duration is too short to permit a concentration of hemoglobin in the majority of men. In order to test the part that the blood changes may play as a compensatory factor for oxygen want in such a short period as the aviator spends in the air, a series of experiments are now being made in the pneumatic chamber and also under low oxygen. In these the subject is held at a chosen pressure or a given percentage of oxygen for from forty to ninety minutes, the entire experiment lasting as much as two or two and a half hours. The hemoglobin has been determined with the Gower-Haldane hemoglobinometer on blood taken from a finger or an ear and also from a vein in the arm. At least 25 per cent. of all men examined have shown a well defined increase in the percentage of hemoglobin (from 4 to 9 per cent.) and the majority some evidence of concentration. It has been most clearly induced at pressures, and percentages of oxygen corresponding to between 18,000 and 20,000 feet. Almost all of the men have had to be held at the high altitudes twenty or more minutes before concentration began to be evident.

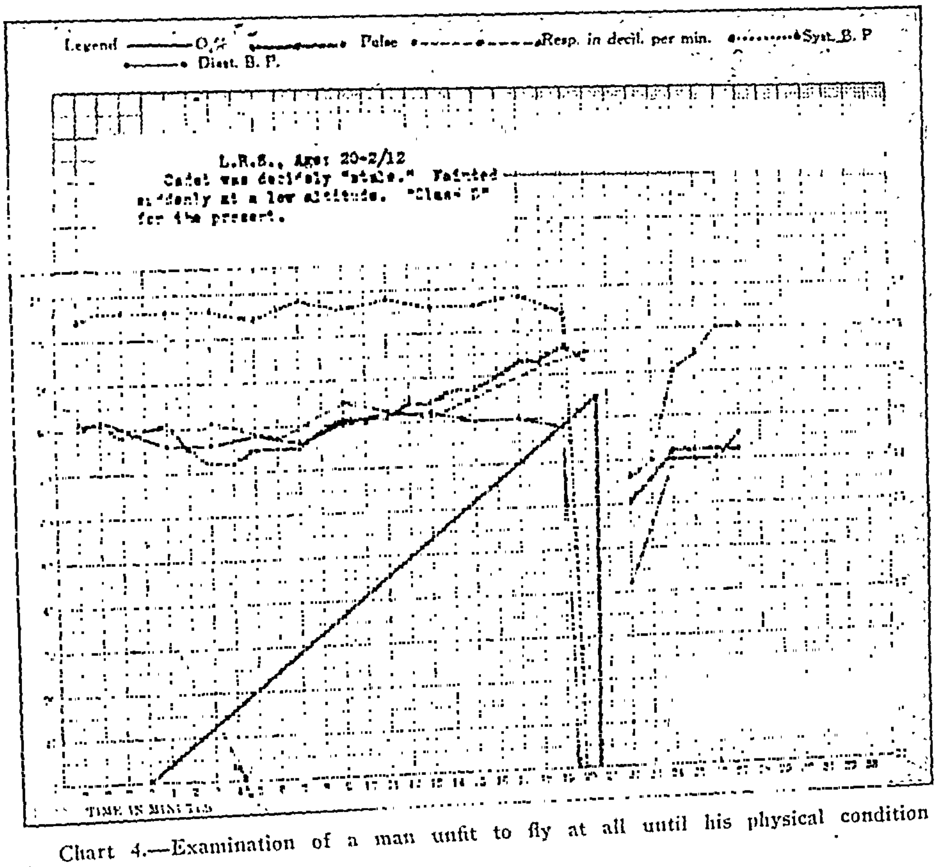

Chart 4.—Examination of a man unfit to fly at all until his physical condition improves.

THE RELATIVE VALUE OF THE COMPENSATORY FACTORS

It is important to obtain a better understanding of the interplay of the compensatory factors when man ascends quickly to very high altitudes and remains only a short time, a few hours at the most. A number of experiments have been made, therefore, with men in the pneumatic chamber, and also under low oxygen, in which they have been held for an hour or two under conditions corresponding to altitudes of from 15,000 to 20,000 feet. In all of these, two of the compensatory changes, those in breathing and circulation, have appeared almost simultaneously and increased steadily with the gradually increasing altitude. When the desired altitude was reached, the breathing either continued at the depth it had acquired during the period of progressive change or it became still deeper for a time. The pulse rate, which gives an index of the increase in the rate of blood flow, accelerated during the period corresponding to ascent and then, when the altitude was held, remained constant or, in some of the men, retarded slightly. The slowing of the pulse rate, when an altitude was thus maintained for a time, was so frequently observed that we sought for an explanation of it. In a number of men it was found that the heart was being relieved by other compensatory factors. In such cases one or the other or both of two changes occurred. There occurred a further deepening of the breathing, or a concentration of the hemoglobin, or both of these changes took place together. Often the breathing, after increasing in amount during the ascent, held at a constant increased depth during the stay at a given altitude; but in such case the hemoglobin was found to be concentrating as the pulse rate slowed. An unusual but interesting case was found in a man whose breathing failed to respond to the changes in altitude. He did not tolerate the low pressure well at first, but felt better after some time had been spent at the chosen pressure. In this man the heart accelerated decidedly, and later his hemoglobin concentrated about 8 per cent. His improvement occurred when the hemoglobin showed concentration.

Our studies show that during short exposures to high altitudes or low oxygen, such as the aviator experiences, the compensatory reactions of the body to a decreased oxygen are made almost entirely by the circulation and by the breathing. A considerable number of men may, after the lapse of about an hour, secure some benefit from a slowly developing concentration of the hemoglobin. The order of response by the adaptive mechanisms is not that of the good reaction seen among mountaineers, in whom the breathing first responds while the other compensatory changes take place more slowly. The reaction resembles more nearly that seen during an attack of mountain sickness among mountaineers. In such men the heart beat is greatly accelerated during the attack. The aviator, it appears, must depend largely on his heart and his breathing for compensation to the fall in oxygen that he encounters as he ascends.

III. CARDIOVASCULAR OBSERVATIONS *

JAMES L. WHITNEY, M.D. (San Francisco)
Major, M. R. C., U. S. Army
MINEOLA, L. I., N. Y.

It has long been known that persons with defective hearts tolerate very badly such altitudes as those of Denver, Phoenix and Mexico City. Many instances have been quoted of serious and even fatal attacks of cardiac dilatation, pulmonary edema, etc., occurring within a few days after the arrival at these places. This popular view has, however, received up to the present very little confirmation from scientific work. Marked alterations in respiration have indeed been described; and the effects on the chemistry of the blood and tissues in reference to transport of oxygen have been studied in great detail. Beyond suggestions, however, that certain changes in blood flow might occur as the result of high altitudes, little evidence has been at hand that the effect on circulation is of great importance; especially there has been entire lack of proof of marked circulatory strain, or of the possibility of such disasters to the heart as have been popularly described.

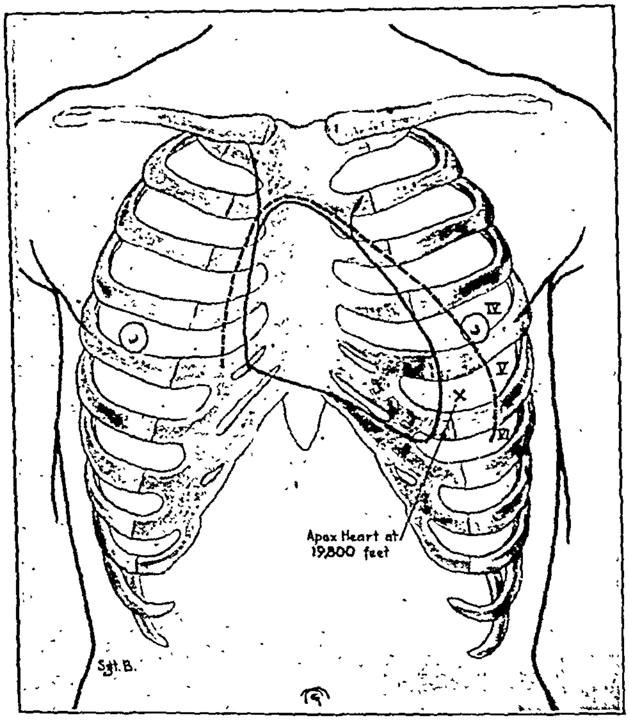

Fig. 1.—Dilatation of the heart under deficiency of oxygen beyond the individual's power of compensation: solid line, percussion outline of heart before and after experiment; broken line, outline at 19,800 feet elevation in low-pressure chamber.

The explanation is that the best type of organism makes its circulatory adjustments so smoothly and with so little strain that there is almost no evidence of anything of great importance going on. It is only by study of less normal types that we appreciate both the serious effects that may be due to failure of circulatory reaction, and the nature of this reaction itself.

Perhaps the most striking single fact brought to light by the present research is that heart failure following marked dilatation is exceedingly common as the result of reduction of atmospheric pressure. Dilatations of from 3 to 5 cm. have been not infrequently found, always followed by collapse and fainting if oxygen is not immediately given. The commonness of this syndrome may be judged from the experience of ten medical officers taken into the low-pressure chamber on two occasions for demonstration purposes. These were men of average constitution, though not of athletic type. Five of them developed marked dilatation, one at 14,000, one at 16,000, two at 18,000 and one at 20,000 feet. It was interesting that in each case the dilatation was discovered by percussion before any subjective symptom was present; but in each case the individual began to feel very ill within a minute thereafter and would have fainted if oxygen had not been administered. It is our practice in using the low-pressure chamber for the observer to take oxygen even at the lower "altitudes."

COMPENSATION BY THE CIRCULATORY SYSTEM FOR LOW OXYGEN

The explanation of many physiologic events lies in the power of the organism to make readjustments to compensate for deleterious changes in the environment. In the compensation for low oxygen, the circulation appears to be the factor of first importance. Changes in respiration, in concentration or chemical constitution of the blood, or in the mechanism of gaseous exchange are important, but they are able to make good only partially for the deficiency. The factor of chief importance with a wide range of adaptability is the rate of blood flow, both in general and as regards special parts. If the blood carries less oxygen per unit, more blood must be sent to the organs that need it in order to furnish the sum total of the amount that is required.

This, of course, means increase in pulse rate, often increase of blood pressure (especially of pulse pressure) and delicate readjustments of blood distribution. All of this calls for accurate control of the vasomotor system and increased strain on the heart. This strain must be carried at a time when the oxygen supply of the heart muscle itself is precarious.

Not only is the maintenance of perfect circulation vitally important for efficient existence at high altitudes, but the heart is itself particularly vulnerable to direct effects of oxygen deficiency. There is the possibility of a vicious circle of a most dangerous kind. For if the circulation falters for a moment, not only will the nerve centers run the risk of subjection to a paralyzing anoxemia, but the nutrition of the heart muscle is impaired. Further interference with circulatory efficiency ensues, and total collapse is inevitable.

Add the fact that this collapse comes practically always without premonitory symptoms of any kind, and the very great danger to the aviator becomes apparent. There is a total reversal of conditions from those of heart strain from vigorous exercise, in which the intense discomfort caused by overexertion gives ample warning that one is approaching the limit, and in which at worst partial failure of the heart would do

---

* From the Medical Research Laboratory, Air Service, Mineola, L. I.

no more than make further exertion impossible, and so automatically terminate the strain.

This vicious circle may satisfactorily explain many cases of sudden fainting at low altitudes. For if there were a momentary failure of coronary circulation due perhaps primarily to a wholly neurotic influence on the vasomotors, a condition of undernourishment of the heart would be started that would be rapidly cumulative.

The elements of strength in meeting the situation are a strong heart muscle, efficient and accurately adjustable coronary circulation, and the ability of the peripheral vasomotors to allow increase of blood flow to the parts that need it without undue strain on the heart by increased blood pressure. These arterial reactions demand in the first line perfect anatomic condition of the vascular walls and perfect vasomotor control. As a consequence, two classes of cases are found that are most likely to react badly to lowered oxygen tension: men who have any arterial change in the way of sclerosis, and those with poor vasomotor control.

The latter class includes numerous individuals who are either overvigorous in their reactions and run a high blood pressure (often high strung, efficient people) or who have fluctuations of vasomotor tone which are manifested in a variety of ways but eventually lead to an identical result, namely, circulatory collapse and fainting, usually following marked dilatation of the heart.

The "optimum" type of individual will go to extreme heights with practically no signs of circulatory difficulty, and will at the end become unconscious from direct effect of oxygen want on cortical centers, giving quite a different picture from that of circulatory collapse.

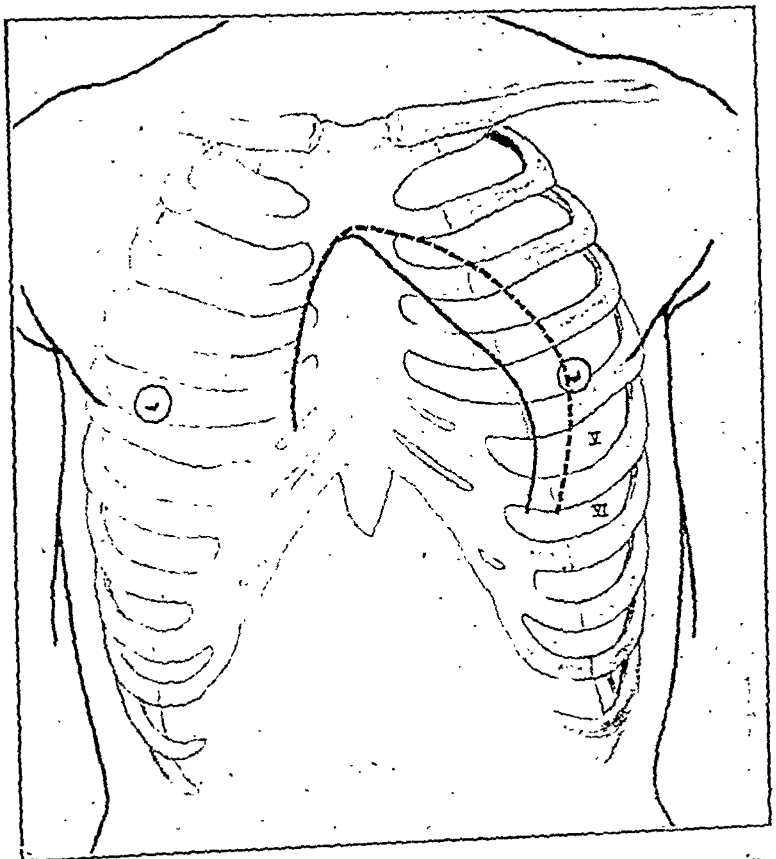

Fig. 2.—Dilatation of the heart at 18,000 feet when man was in poor condition; when feeling well, this man could go 5,000 feet higher without any ill effects: solid line, outline of heart before and after experiment; broken line, heart outline to percussion at elevation of 18,000 feet.

FAILURE TO COMPENSATE

Paradoxically enough, the poorer types of organisms also fail to show heart strain and dilatation. Persons of poor physical and sluggish reactions, whether by nature or because of sedentary life and lack of exercise, ordinarily show a more or less marked failure of the compensations demanded for efficient existence under the altered conditions. They show little or no quickening of the pulse, and no change, or even a fall, in blood pressure. They simply become inefficient instead of making the strain.

Many types with defective hearts and blood vessels do not show heart strain because, having tried to meet the requirements, and having found it impossible, they give up the fight and fail.

Those who do show it, as previously suggested, are persons of vigorous reactions, especially high strung types, but are often "out of condition" for one reason or another. The influence of factors of condition, which are too often underestimated, has been found to be very great. Dissipation, nerve strain, slight infections, may involve heart weakness or abnormal vasomotor reactions which overstrain or undernourish the heart, and thus cause the aviator's death.

CONDITION

The influence of "condition" is a point of the greatest practical importance, of course. One of our hardiest subjects illustrated this. He had been in the low-pressure chamber on one occasion at an elevation of 23,000 feet for some minutes and remained in practically perfect condition. The following day the experiment was repeated; but on the evening between he had dined late with friends, with the usual but not excessive accompaniments. When the altitude of 18,000 feet was reached on the second test he was found to be completely inefficient; he was markedly cyanotic; his heart was dilated 3 cm., and the heart sounds were of very poor quality. He would have collapsed in another minute if oxygen had not been administered.

The question of just what is involved in "good condition" has received much consideration. On the basis of our present knowledge, the most important element seems to be normal vasomotor control, that is, adequate nourishment of the tissues with a minimum of strain on the heart. In this the coronary circulation is of first importance. Other factors are, doubtless, the strength and condition of the heart muscle and probably certain matters of general metabolism, for example, the ability to generate energy rapidly without the accumulation of harmful waste products.

The practical result of this knowledge of the strain on the circulatory system involved in aviation, and the paramount importance of "condition," bear on both the selection and the maintenance of the flying personnel. Only those men should be allowed to fly who possess faultless circulatory systems; and once in the service, aviators deserve the most scrupulous oversight to keep them in as perfect condition as a well-trained football team, and to prevent them from going into the air when they are not in condition.

LOW OXYGEN AS A FUNCTIONAL HEART TEST

As far as the selection of men with perfect circulation is concerned, we possess fortunately a wonderful diagnostic agent in the low oxygen test, to which eventually all flyers will be subjected. We have come to regard the Henderson rebreathing apparatus as affording by far the most efficient test of the heart, from both anatomic and functional points of view, that we possess.

The strain of making good for low oxygen tension in the atmosphere is so great that any latent defect, fully compensated and not to be discovered by ordinary methods of examination, becomes glaringly apparent during a rebreathing test.

The question of anatomic condition of the valves, however, is not the only consideration with regard to a heart. Many a damaged heart will compensate so well, as the result of the quality of the heart muscle, that its functional power may even be above normal. Clinicians have long been searching for a functional heart test which would tell them, not what the heart was anatomically, but what it could do. In the low oxygen methods we have just such a test, and it should be of great value in ordinary clinical work.

In the case of well compensated valvular disease, murmurs develop under low oxygen or become much stronger, and accentuation of heart sounds takes place, indicating hypertrophy of the left ventricle or back pressure through the lungs; the blood pressure is high and the heart is evidently overworking seriously. Often in young men such a heart will be fully as successful as a normal one in meeting the demands made on it in ordinary life; in fact, overcompensation is the rule rather than a failure to compensate. But under the low oxygen test the underlying defect is revealed.

In the case of valvular lesions that are less well compensated, the heart is more readily reduced to incompetence; after the period of overwork there is marked cyanosis, excessive discomfort, and insufficiency of the peripheral circulation, most delicately shown by inability to perform well on the psychologic apparatus that forms part of the rebreathing test.

In subjects with arterial disease there is a more or less marked rise in blood pressure owing to inability of the peripheral vessels to make way for the increase of blood flow without throwing a much increased strain on the heart. At the same time there is doubtless insufficiency of the coronary circulation as well, so that between high blood pressure and poor nutrition the heart muscle soon becomes incompetent; the heart sounds deteriorate rapidly in quality, and the peripheral circulation becomes insufficient.

Tendencies to arrhythmia are brought out in a remarkable way by the rebreathing apparatus: several hearts that showed at the start only an occasional extrasystole have become arrhythmic to a degree that was positively alarming. We suspect that there is the possibility of danger in this method of examination for hearts showing difficulty of conduction or in which there is a possibility of the development of ventricular fibrillation.

One of the most gratifying features of this work has been the direct bearing of the observations on fundamental questions of circulatory physiology and pathology. In this way they go far beyond the narrow field of aviation medicine in their scope. It is impossible here to discuss thoroughly the many side-lights thrown on clinical medicine. A few of these points may, however, be briefly mentioned.

One is the supreme importance of normal vasomotor control in connection with circulatory efficiency, which means general efficiency as well. Abnormal vasomotor reactions mean either high blood pressure with excessive heart strain if the demands on the circulation are met, or inefficiency if the demands are not met.

The behavior in the test of subjects with more or less marked arteriosclerosis has been of the greatest value in understanding the effect of arterial change[1] under conditions of ordinary life. An interesting fact is brought out by the behavior in the test usually shown by subjects in their thirties, which suggests that arterial change at this age is commonly already considerable. This may account to a large degree for the well known fact that 20 is the best age for flyers, and that every year above this decreases the likelihood of their being able to stand the strain of hard service.

The relation of nerve tension to vasomotor control is a subject on which we have been able to throw some light, and our results fit in well with the demonstration by the British commissions of the intimate relation of the vasomotor system to shell shock, trench neuroses, irritable heart and allied conditions that have contributed so largely to the disabilities of this war. The frequency with which slight cardiac lesions have been demonstrated among presumably healthy men has been striking. Even among a class of men as carefully picked as American aviators we have found more than 5 per cent. These were usually cases that could hardly have been demonstrated by ordinary means of examination, and would have passed the most rigid inspection as "functional heart murmurs" or at worst as borderline cases with a wide margin of safety. Every one who has worked on the Army cardiovascular boards knows how common and how troublesome such cases are; and the British experience shows that men who genuinely have slight organic lesions will not stand up under modern war conditions. For this kind of work the low oxygen test should be of the greatest value.

Similar to this class of cases are "athletic hearts," which we have very frequently encountered among aviators, who are to a large extent drawn from the ranks of college athletes. Such hearts behave very badly under low oxygen. They show high blood pressure, marked heart strain, with exhaustion and eventual collapse. Without entering into any discussion of the question, it may be said that our evidence points strongly to the belief that the so-called "athletic heart" represents not a faulty involution of a normally hypertrophied heart, but a heart that has either been definitely injured by strain, or one with an underlying vascular lesion too slight or too well compensated to be discovered. We have demonstrated slight old mitral insufficiency in several men whose names are familiar on the sporting page of the papers.

---

[1] See Chart 2 in the preceding paper of this series.

Quackery on Both Sides of the Ocean.—Under this heading Dr. Pinkhof comments in the *Nederlandsch Tijdschrift* on the efforts made by the osteopaths to get appointed to the medical corps of the United States Army. He says: "Dr. Gorgas and his staff are better antimonopolists in fact than the legislators in our land (the Netherlands). Our legislators would like to provide a monopoly for the quacks, that is, to confer on them the exceptional privilege of practicing medicine without fulfilling the conditions which every honest citizen has to fulfil. At a recent representative meeting of the organized pharmacists of the Netherlands, the chairman, H. L. Visser, gave a good definition of quackery which may well be taken to heart by every one. He said, 'Quackery, whatever its form, is a gambling game, with life for the stakes and health as the highest prize.'"

IV. PSYCHOLOGIC OBSERVATIONS AND METHODS*

KNIGHT DUNLAP (Baltimore)
Major, S. C., N. A.
Mineola, L. I., N. Y.

The psychologic tests now used in determining the ability of candidates for the aviation service to withstand altitude have been developed for use under the practical conditions of the Henderson rebreathing apparatus, in which the rate of oxygen decrease is rapid. The statements made here with regard to the course of the phenomena apply only to conditions of brief ascents, and do not necessarily hold in all particulars for cases in which the aviator is kept at corresponding altitudes for long periods of time.

The effects of oxygen insufficiency on the physiologic process were in the beginning of our work studied empirically, with the least possible hypothetic guidance. Our results square distinctly with the conception of psychologic processes as integrative, that is, as dependent on the working together of the central nervous system as a whole rather than on the action of any specific parts of the system.

The basic and important psychologic effects of oxygen deficiency are on voluntary sensorimotor coordination and attention. Until asphyxiation reaches the stage in which the integrative mechanism is rapidly approaching the condition of complete failure, no effects are demonstrable that are not clearly the failure of the one or the other, or both, of these two mental factors. In the prefinal stages perception is as efficient as the muscular control of the sense organs and organs of expression, and the power to attend to the stimuli, permit. Discriminative judgment, likewise, shows no falling off in rapidity or accuracy except as impaired motor control and attention produce it. Memory, both "immediate memory," as tested by the ability to reproduce what has been perceived or learned immediately before, and "true memory," as tested by the ability to reproduce something that has been "latent" for a certain interval after being learned, is apparently not affected, except as the inability to attend to the details in learning or in reproducing, or inability to control the muscular mechanism of expression, may enter. The efficiency of limited neuromuscular groups, as indicated by dynamometer tests, is not impaired in the prefinal stages of asphyxiation.

As instances of tests involving perception and discrimination, we may cite the copying of a list of words and the translation of words into code. In both of these cases, speed and accuracy are maintained up to the final stages of asphyxiation, provided the muscular mechanism of accommodation and convergence is not seriously affected; although the mechanism for handwriting may be so affected that the written results of the list are legible with difficulty.

In more complicated discrimination, in which rapid and accurate recognition and classification of material are required, the results are similar. Ability to locate correctly on a chart the positions of objects previously seen is unimpaired up to the point at which the individual's coordinations of movement become so much affected that the charting is defective on that account.

It is interesting to note that the sensitivity and acuity of the sense organs show no consistent impairment, and that apparently the speed of simple reactions (the simple reactions do not, in general, require a high degree of integration) is not intrinsically diminished. More work remains to be done on simple reactions, however, before definite statements can be made. The distinctive effect on the nervous system, in short, seems to be a change in its integrative action, and not a change in the efficiency of any particular part or unit. The whole picture of progressive asphyxiation, from a psychologic point of view, is strongly suggestive of the picture of progressive alcoholic intoxication.

Under the practical requirements of rating, tests must be single and brief, during progressive depletion of the oxygen supply. If many individuals are to be examined it is not practicable to spend even several hours on each one. Hence it is not possible to hold the subject at a moderately high altitude, such that asphyxiation effects will eventually appear. Nor is it possible to repeat a briefer test a number of times. Hence, the subject must be allowed to rebreath himself rapidly (during not much over a half hour, at most) to a low point of oxygen tension, reaching his maximal "altitude" for that rate of "ascent." It follows that the method used must be one which is not approved for psychologic work under other conditions, and which, for want of a better term, is called clinical. That is, since the reactor's condition is rapidly changing from minute to minute, we must be able to determine at any minute his psychologic condition, and cannot use the method (more exact under other conditions) of determining the average speed and accuracy of work done during a period of several minutes.

It was early discovered that under asphyxiation, as under alcoholic intoxication, it is possible for a reactor to "pull himself together" for a brief span of time (a minute or even several minutes), during which his efficiency on a set task may be as high as in his normal condition, or even higher, sinking at the termination of the task to a relatively low level of efficiency. If given a series of tasks, with brief resting intervals between, the reactor may therefore accomplish a performance that is practically normal, even up to a minute or two before the point at which complete lapse of integration occurs. In this way, his real psychologic deterioration may be concealed. It is necessary, therefore, to set a task which, although minimally fatiguing, is practically continuous, allowing the reactor no expected periods in which no work will be demanded of him, and thus preventing him from making use of attention peaks, as the phases of "pulling himself together" may justly be called. In determining the sensitivity or acuity of sense organs, on the other hand, the "attention peaks" are precisely in order, and pause should be taken to present the stimuli at the highest peaks.

It is probable that in earlier work on the action of alcohol and other drugs, and of fatigue, many failures to find psychophysical effects were due to the evoking of attention peaks by brief or periodic tests, thus masking the real condition of the patient tested.

Many tests that otherwise would be applicable impel the reactor to hold his breath during the crucial moments. The conventional steadiness test is one of this sort. If the reactor, already suffering from oxygen deficiency, holds his breath for twenty seconds, or largely reduces his breathing during that period, he makes a large change in his oxygen supply. Hence the purpose of the test is largely defeated. The steadiness test, and others in this class, although some show marked effects of low oxygen tension, cannot be used.

---

The apparatus used in administering the psychologic test we have called the "L V F" apparatus. The principal parts of the apparatus are assembled on a table with a top adjustable in height and slope, supported on a single heavy post from a cast iron base. This table (the so-called Dunlap table) is designed to give the necessary rigid but convenient mounting.

APPARATUS AND METHOD OF TESTING

The apparatus mounted on the table is designed to require attention and reaction on the part of the man undergoing the test analogous to the conditions of the pilot in the air. It allows the slightest deviation of reaction or lapse of attention to be noted. It consists of three separate units:

1. A series of fourteen stimulus lamps (2 candle power) arranged in two rows of seven each, with two similarly arranged rows of contact buttons, each button surrounded by a metal washer; a green check lamp and a red error lamp, and a stylus with a hard rubber handle and metal tip. These parts of the unit are so wired electrically that when a stimulus lamp is lighted the corresponding contact button is "alive," and if touched with the metal tip of the stylus causes the check lamp to light. If the washer surrounding any of the buttons is touched with the stylus at any time, the error lamp is lighted.
2. Two ammeters, mounted on a metal arm above the table top. These are connected in series with two rheostats, one on the upper side of the table top at the edge nearer the reactor, the other underneath, at the edge nearer the observer. One ammeter faces the reactor, the other the observer. A change in the resistance made by the observer at his rheostat, causing a change in the ammeter reading, may be compensated for by a change in the reactor's rheostat, by which the original ammeter reading may be restored.
3. A small electric motor, mounted on the upper side of the table top. This motor is connected in series with a third rheostat underneath the table. A two-way lever switch mounted underneath the table at the observer's edge and a rocking pedal two-way switch on the floor under the table, connected with the rheostat, can be cut out (thus increasing the speed of the motor) by either switch, and again cut in (thus restoring the lower motor speed) by either switch.

In order to control the fourteen stimulus lamps, lighting them at the proper time, an accessory piece of apparatus is mounted on a small table in any convenient position, and electrically connected with the apparatus on the Dunlap table. At first, this accessory apparatus consisted of a button board, having fourteen buttons corresponding to the fourteen lights; and from these buttons an enlisted man controlled the lighting of the stimulus lamps, timing his actions by a stop-watch. For this button board an automatic distributor is now being substituted, which both times and selects the lights, being operated by a synchronous motor.

Before the rebreathing is commenced, the reactor is given carefully formulated instructions, and if necessary he is coached during the first three minutes of the work. His tasks are as follows: 1. As soon as a stimulus lamp lights he must touch with the stylus, held in the right hand (except in the case of left-handed subjects), the corresponding "button," touching it accurately and carefully. 2. Whenever the motor increases speed, as indicated by a change in its sound, he must bring the speed down to normal again by throwing his pedal switch. 3. When the hand of the ammeter is changed from its standard position, he must bring it back to standard by varying the position of the rheostat handle.

During the early part of the test, the psychologist notes the composure and attention of the reactor, and his comprehension of the instructions; also his motor tendencies, which are recorded in a fixed scale of types. Further, the psychologist watches for the beginning of the effects of oxygen deficiency on attention and coordination; for the moments at which these effects attain a certain standardized importance, and for the final moment of "complete inefficiency," which will be followed very quickly by a complete breakdown and unconsciousness unless the reactor is given air. Since the change in the reactor's condition is very rapid at this phase, and the effects on the nervous system lag behind the respiratory conditions somewhat, prompt relief is necessary, or the reactor may become unconscious after being given air: before the renewed air supply "catches up" with the nervous system, as it were.

RESULTS

The various ways in which the effects on coordination and attention are manifested in different reactors have been carefully analyzed and studied, and, as a result, very satisfactory results are obtained.

In addition to the practical application of the tests to the rating of aviators, we have obtained results that have considerable scientific value for future psychologic work. The application of our general method (that is, involving a group of continuous tasks) to the study of problems of drug and fatigue action is an obvious possibility. Our specific apparatus and routine are adapted to the oxygen rating problem alone, but modifications to suit the purposes of research may be readily made. One such modification has been made already by Captain Dockeray, for work on fatigue and "staleness," and is being given thorough trial. Carefully worked out series of experiments on discrimination and judgment, code translation, mathematical operations, memory, auditory functions, etc., have been made under the supervision of Captains Dockeray and Johnson and myself for the purpose of checking my earlier results, and tests on handwriting have been made by Major Watson in the low pressure tank. These, in addition to their bearing on the rating tests, have produced important scientific results.

In working on the psychologic factors in blood pressure changes, striking indications of the presence of which appeared in the rating tests, we have found strong evidence that apprehension is uniformly accompanied by a rise in systolic pressure, which tends shortly to return to normal, but that when actual fear is present the rise is much more sustained. The conditions under which the rise due to apprehension occurs are somewhat complicated; we should have reason to expect it under practical conditions, for example, when the flying cadet is notified that he is to make a flight, with possibly entire subsidence a short time later when he actually gets into the machine.

Some Thrift Expedients in Germany.—P. Bonnette relates in the *Presse médicale* of recent date that the Germans are putting up fruits with tablets of sodium benzoate and sodium cinnamate, without sugar. The sugar can be added when they are to be served if desired. Milk to be transported any distance is frozen in large cakes kept in isolating containers. Fallen leaves are collected in large quantities, dried in ovens, ground, mixed with molasses and pressed into cakes which are fed to animals in the place of oats. He quotes a Munich paper to the effect that these dried leaves make excellent fodder for animals, especially the leaves of the elder. They are said to be richer in albumin than hay, and easier to digest as they do not contain so much cellulose. Visitors to the Leipzig fair were notified that they must bring their own tablecloths and napkins if they wanted any. Shrouds for the dead are made of paper, and he states that it is being debated whether to make it compulsory to exchange the clothes of the dead for paper substitutes.

IV. PSYCHOLOGIC OBSERVATIONS AND METHODS*

KNIGHT DUNLAP (Baltimore)
Major, S. C., N. A.
Mineola, L. I., N. Y.

The psychologic tests now used in determining the ability of candidates for the aviation service to withstand altitude have been developed for use under the practical conditions of the Henderson rebreathing *apparatus, in which the rate of oxygen decrease is* rapid. The statements made here with regard to the course of the phenomena apply only to conditions of brief ascents, and do not necessarily hold in all particulars for cases in which the aviator is kept at corresponding altitudes for long periods of time.

The effects of oxygen insufficiency on the physiologic process were in the beginning of our work studied empirically, with the least possible hypothetic guidance. Our results square distinctly with the conception of psychologic processes as integrative, that is, as dependent on the working together of the central nervous system as a whole rather than on the action of any specific parts of the system.

The basic and important psychologic effects of oxygen deficiency are on voluntary sensorimotor coordination and attention. Until asphyxiation reaches the stage in which the integrative mechanism is rapidly approaching the condition of complete failure, no effects are demonstrable that are not clearly the failure of the one or the other, or both, of these two mental factors. In the prefinal stages perception is as efficient as the muscular control of the sense organs and organs of expression, and the power to attend to the stimuli, permit. Discriminative judgment, likewise, shows no falling off in rapidity or accuracy except as impaired motor control and attention produce it. Memory, both "immediate memory," as tested by the ability to reproduce what has been perceived or learned immediately before, and "true memory," as tested by the ability to reproduce something that has been "latent" for a certain interval after being learned, is apparently not affected, except as the inability to attend to the details in learning or in reproducing, or inability to control the muscular mechanism of expression, may enter. The efficiency of limited neuromuscular groups, as indicated by dynamometer tests, is not impaired in the prefinal stages of asphyxiation.

As instances of tests involving perception and discrimination, we may cite the copying of a list of words and the translation of words into code. In both of these cases, speed and accuracy are maintained up to the final stages of asphyxiation, provided the muscular mechanism of accommodation and convergence is not seriously affected; although the mechanism for handwriting may be so affected that the written results of the list are legible with difficulty.

In more complicated discrimination, in which rapid and accurate recognition and classification of material are required, the results are similar. Ability to locate correctly on a chart the positions of objects previously seen is unimpaired up to the point at which the individual's coordinations of movement become so much affected that the charting is defective on that account.

It is interesting to note that the sensitivity and acuity of the sense organs show no consistent impairment, and that apparently the speed of simple reactions (the simple reactions do not, in general, require a high degree of integration) is not intrinsically diminished. More work remains to be done on simple reactions, however, before definite statements can be made. The distinctive effect on the nervous system, in short, seems to be a change in its integrative action, and not a change in the efficiency of any particular part or unit. The whole picture of progressive asphyxiation, from a psychologic point of view, is strongly suggestive of the picture of progressive alcoholic intoxication.

Under the practical requirements of rating, tests must be single and brief, during progressive depletion of the oxygen supply. If many individuals are to be examined it is not practicable to spend even several hours on each one. Hence it is not possible to hold the subject at a moderately high altitude, such that asphyxiation effects will eventually appear. Nor is it possible to repeat a briefer test a number of times. Hence, the subject must be allowed to rebreath himself rapidly (during not much over a half hour, at most) to a low point of oxygen tension, reaching his maximal "altitude" for that rate of "ascent." It follows that the method used must be one which is not approved for psychologic work under other conditions, and which, for want of a better term, is called clinical. That is, since the reactor's condition is rapidly changing from minute to minute, we must be able to determine at any minute his psychologic condition, and cannot use the method (more exact under other conditions) of determining the average speed and accuracy of work done during a period of several minutes.

It was early discovered that under asphyxiation, as under alcoholic intoxication, it is possible for a reactor to "pull himself together" for a brief span of time (a minute or even several minutes), during which his efficiency on a set task may be as high as in his normal condition, or even higher, sinking at the termination of the task to a relatively low level of efficiency. If given a series of tasks, with brief resting intervals between, the reactor may therefore accomplish a performance that is practically normal, even up to a minute or two before the point at which complete lapse of integration occurs. In this way, his real psychologic deterioration may be concealed. It is necessary, therefore, to set a task which, although minimally fatiguing, is practically continuous, allowing the reactor no expected periods in which no work will be demanded of him, and thus preventing him from making use of attention peaks, as the phases of "pulling himself together" may justly be called. In determining the sensitivity or acuity of sense organs, on the other hand, the "attention peaks" are precisely in order, and pause should be taken to present the stimuli at the highest peaks.

It is probable that in earlier work on the action of alcohol and other drugs, and of fatigue, many failures to find psychophysical effects were due to the evoking of attention peaks by brief or periodic tests, thus masking the real condition of the patient tested.

Many tests that otherwise would be applicable impel the reactor to hold his breath during the crucial moments. The conventional steadiness test is one of this sort. If the reactor, already suffering from oxygen deficiency, holds his breath for twenty seconds, or largely reduces his breathing during that period, he makes a large change in his oxygen supply. Hence

COLOR VISION

Normal color vision is considered a requisite for a good pilot by all Allied air services. The object of our tests has been to determine the effect of low oxygen tension on color vision.

Stilling's plates were used in these tests. Five subjects were examined in the low-pressure tank and carried to 20,000 feet or above. Five subjects were examined on the rebreathing apparatus and carried above 20,000 feet. This series of subjects, during the entire experiment, showed no change in color vision. Threshold color vision will be considered under retinal sensitivity.

FIELD OF BINOCULAR FIXATION

It is important that the aviator be able to carry the eyes as far as possible in the various directions without seeing double. If a man has a contracted field of fixation, it necessarily impairs his ability in flying. The field of binocular fixation has been taken by means of the Schweiger perimeter modified for binocular use or by means of a large tangent screen, the Wilmer wand and Wilmer glasses being used. Of 122 men acceptable for the Aviation Section, Signal Corps, who have been examined and sixteen who were not acceptable, 7.37 per cent. of the normals showed contraction of the field of binocular fixation, and 50 per cent. of the subnormal men showed contraction. Narrowing of the field was most marked above.

MUSCLE BALANCE

Normal muscle balance should be insisted on, for even a small defect may be accentuated by the strain of flying and lack of oxygen, resulting in diplopia or at least a marked contraction of the field of binocular fixation at low altitudes. Exophoria and hyperphoria are more serious than esophoria. Twenty-five men, ocularly acceptable for the Aviation Section, Signal Corps, were examined in the low-pressure chamber and on the rebreathing apparatus. Abduction decreased 1.31 degrees at 15,000 feet and 1.55 degrees at 20,000 feet. Adduction decreased 1.75 degrees at 15,000 feet and 1.90 degrees at 20,000 feet. Sursumvergence decreased 1.15 degrees at 15,000 and 1.25 degrees at 20,000 feet.

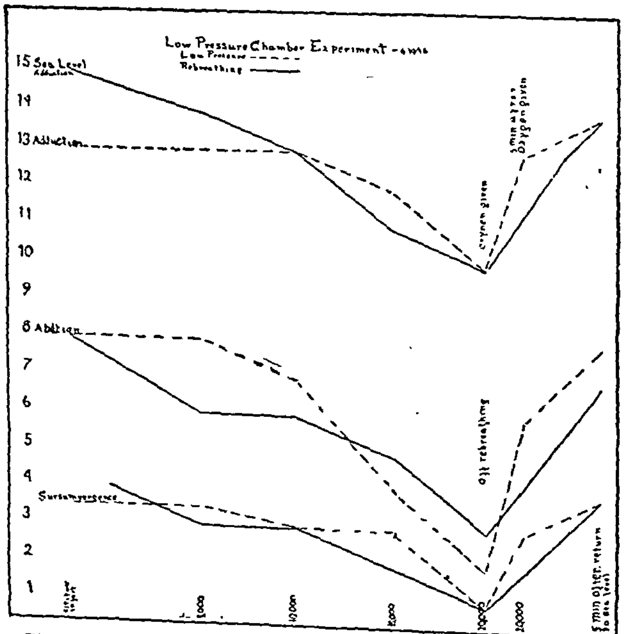

Fig. 2.—Effect of lack of oxygen on the strength of the ocular muscles. Rebreathing and low-pressure findings compared. Note return of strength on administration of oxygen, even when under low barometric pressure in the decompression chamber.

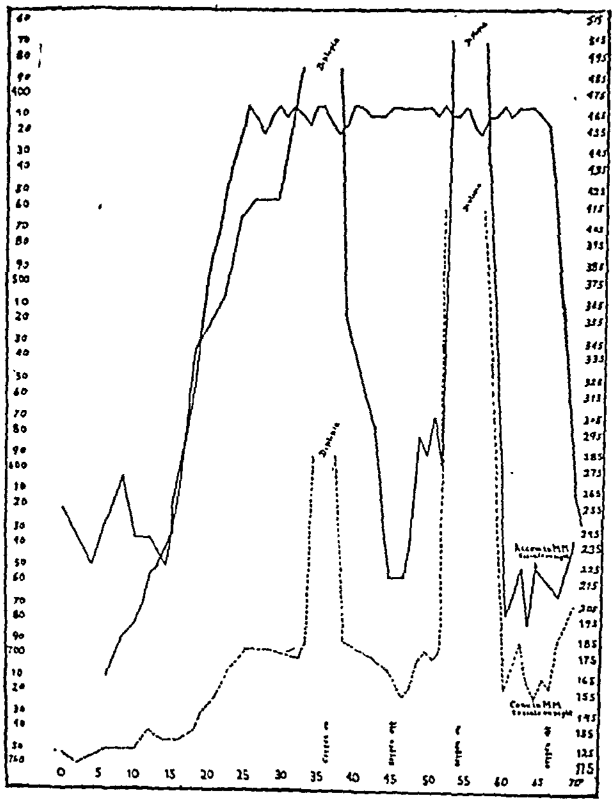

Fig. 3.—Falling off of accommodation and convergence in low-pressure chamber and return of strength on administration of oxygen.

FIELD OF VISION

Every aviator insists primarily on the broadest visual field obtainable; and in view of the fact that the research work done shows a contraction of the visual field under lowered oxygen tension, it is important to see that poorly constructed goggles do not further cut down the fields.

The fields for form and color have been taken in the low-pressure chamber at 5,000, 10,000, 15,000 and 20,000 feet; and when contraction is noted at 20,000 feet, oxygen is administered. To make sure that the changes are not due to fatigue, controls have been taken at sea level corresponding in time of day and in time interval to those taken in the low-pressure chamber. At 5,000 and 10,000 feet there is usually a slight enlargement of the fields for form and color, at 15,000 a slight contraction, and at 20,000 a marked contraction. Twenty men have been examined, and at 20,000 feet the fields for form have shown a contraction of 14 per cent. of their original size below, 3.5 per cent. in the temporal field, 4 per cent. above, and 8 per cent. in the nasal field. The red has lost 9 per cent. below, 6.5 per cent. temporally, 4 per cent. above, and 6 per cent. nasally. The green, 4.5 per cent. in the lower, 5 per cent. in the temporal, 5 per cent. above, and 25 per cent. in the nasal field. Five minutes after returning to sea level, fields are normal in size. Giving oxygen at 20,000 feet for four or five minutes causes a return of the field to normal. Several fields have been taken on the rebreathing apparatus, and the results are fairly comparable with those found in the low-pressure chamber.

PERCEPTION OF MOTION AND ITS DIRECTION BY THE RETINA

Perception of motion and its direction is of great importance to the aviator, and a test has been devised in this laboratory that will give some indication of the flier's power in this respect. The best pilots feel that by constant practice they may develop this important function to a marked degree. The test is performed with the subject seated 15 inches from a Bjerrum screen, fixing with both eyes a 3 mm. white pin placed in the screen on a level with the eye. A small light, which is visible through the cloth or neutral gray paper is used as the test object. The point at which the test object is first noted and where the direction of motion in three planes is first accurately described is recorded on a chart for use with the tangent screen. In the men examined so far, there is an average difference of 10 degrees between the time when the test object is first noted and the direction of motion is accurately described. It is hoped that this test may prove of value in the selection of aviators for special work; for example, scouting and fighting.

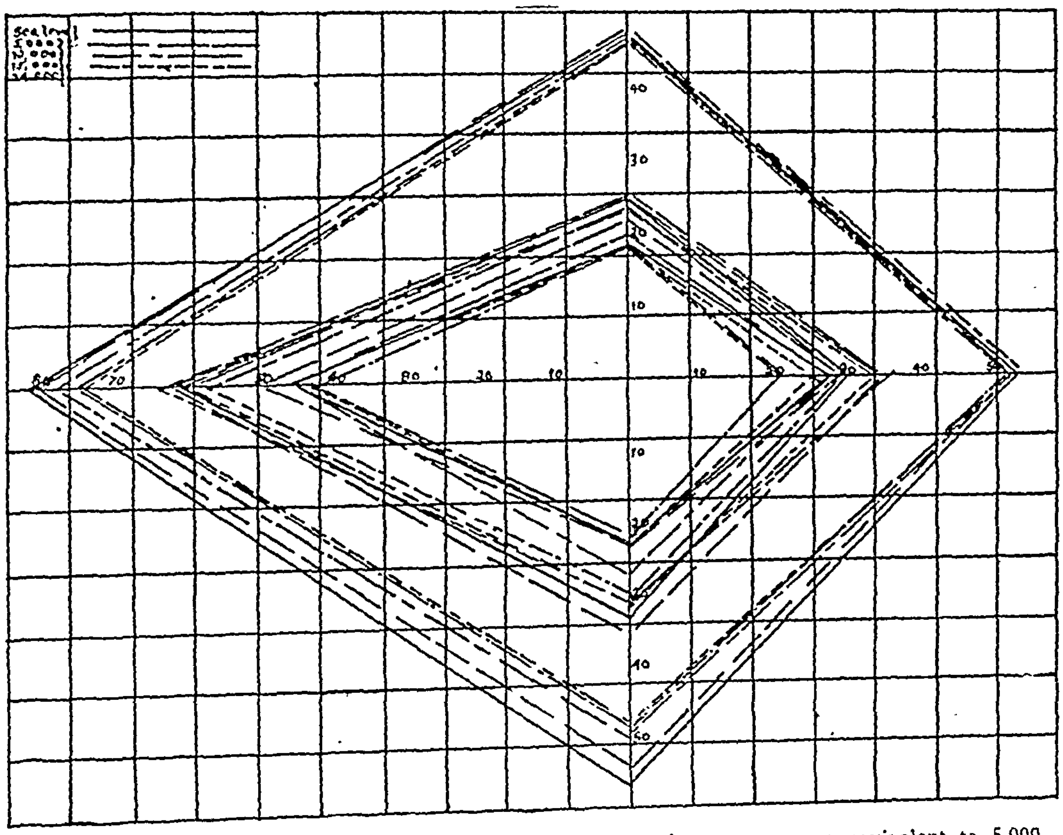

Fig. 4.—Contraction of field of vision in low-pressure chamber at pressures equivalent to 5,000, 10,000, 15,000 and 20,000 feet.

THE EYE AND THE EQUILIBRIUM

The eye is one of the many factors in the complicated problem of maintaining equilibrium. That many aviators depend largely on their visual impressions in the maintenance of equilibrium is evidenced by the fact that many of them tie a piece of string as a streamer to one of the forward struts, thus to obtain the first sign of a side slip while flying in a cloud.

INTRA-OCULAR TENSION

In connection with the various aviation problems, where there is the factor of lowered barometric pressure as well as lowered oxygen tension, the intra-ocular tension has been taken at different altitudes. Fourteen men have been examined in the low-pressure chamber. The examinations so far have not been numerous enough to draw very definite conclusions. We have found, however, no correlation between the intra-ocular tension and the blood pressure, lowered oxygen tension and various cardiovascular changes. Later on, a detailed report on this subject will be possible.

ACCOMMODATION IN FLYING

It is important that the flier maintain his ability to accommodate under all conditions to which he is subjected, for his life may depend on his ability to see clearly. The near point of accommodation has been taken every minute in the low-pressure chamber and on the rebreathing apparatus, a Prince rule with Jaeger test type or the Duane disk being used as a test object. Normal runs have been made without the low oxygen tension effect for the purpose of comparison. One hundred and forty-eight men, acceptable for the Aviation Service as fliers, were examined on the rebreathing apparatus. Of these, 44.6 per cent. showed a receding of the near point, and 18 per cent. showed improvement, fluctuating changes in accommodation were noticed in 14.4 per cent., and no change in 23 per cent. Eleven subnormal cases were examined, and 63.7 per cent. manifested a decrease in accommodative power, 18.3 per cent. an apparent increase, 9 per cent. no change, and 9 per cent. variable reactions. The low-pressure chamber findings were practically the same as those with the Henderson rebreathing apparatus. Of seventeen normal men examined, 47 per cent. showed decrease in accommodative power, 11.7 per cent. increase, 23 per cent. fluctuation, and 17.8 per cent. no change. Three subnormal subjects were examined in the low-pressure chamber; two showed a decrease in accommodative power, and the other gave a varying reaction. When the subject is brought to sea level the accommodation comes back rapidly in some and slowly in others. The inhalation of oxygen invariably causes a return to normal, even though the subject may be kept at 20,000 feet in the low-pressure chamber.

That these changes do not follow the cardiovascular reactions is shown by the fact that fifty-seven men, exhibiting acceleration of pulse rate and maintenance of pulse pressure, showed in 42.1 per cent. decrease in the power of accommodation, and 15.8 per cent. increase in power of accommodation, 15.8 per cent. fluctuation in accommodation, and 36.3 per cent. no change in accommodation. Our researches would lead us to believe that hyperopes and subjects with a marked amount of hyperopic astigmatism show the most marked changes in accommodation.

Fatigue of accommodation has been studied with Howe's ophthalmic ergograph as modified by Captain Berens. Normal three-minute runs were made without the low oxygen tension effect as controls; then three-minute runs with the same time interval were made in the low-pressure chamber and on the rebreathing apparatus. The findings on the rebreathing apparatus and in the low-pressure chamber showed, at 15,000 feet, a more rapid onset of fatigue than was evidenced by the controls; and at 20,000 feet, the fatigue was marked. The administration of oxygen in the low-pressure chamber or rebreathing apparatus rapidly restored the normal tone of the ciliary muscle.

CONVERGENCE

The near point of convergence has been tested, because of the belief that the aviator should have binocular vision and that a weakness in convergence, which might lead to diplopia, would certainly impair his efficiency and could easily result in an accident. A U-shaped piece was cut out of the Prince rule to fit over the nose, and a 2 mm. black dot on a white background was used as a test object for making this determination. Readings were taken without low oxygen tension effect and with low oxygen tension effect, and the effect of the administration of oxygen was determined. Readings were taken every two minutes and charted. One hundred and forty-seven men with normal eyes were examined on the Henderson rebreathing apparatus, of whom 50.3 per cent. showed decrease in convergence power, 17.6 per cent. increase, 11.5 per cent. fluctuation, and 20.6 per cent. no change.

Of eleven subnormal men examined (six were disqualified for visual acuity and five for muscular imbalance), 45.7 per cent. showed decrease in power of convergence. Increased converging power, fluctuating changes and no change in the near point of convergence were each noted in 18.1 per cent. Of sixteen normal men examined in the low-pressure chamber, 50 per cent. showed falling off in power of convergence, none showed increase, fluctuating reactions were present in 12.5 per cent., and 37.5 per cent. remained unchanged. In the subnormal group the recession of the near point was very marked, sometimes resulting in diplopia.

It was attempted to show what relationship, if any, exists between the convergence and the cardiovascular reactions to low oxygen tension. Seventy-two subjects showing an increase in pulse rate and a maintenance in pulse pressure gave these convergence changes, which would seem to indicate the ocular changes cannot be predicted by the cardiovascular reaction and vice versa: 54.2 per cent., decrease in power of convergence; 15.3 per cent., increase; 9.7 per cent., fluctuation, and 20.8 per cent., no change. The results would indicate that the Henderson rebreathing apparatus and low-pressure tank give almost identical findings, and in each case the determining factor seems to be the lowering of oxygen tension, because the administration of oxygen soon causes the convergence near point to return to normal, irrespective of the barometric pressure.

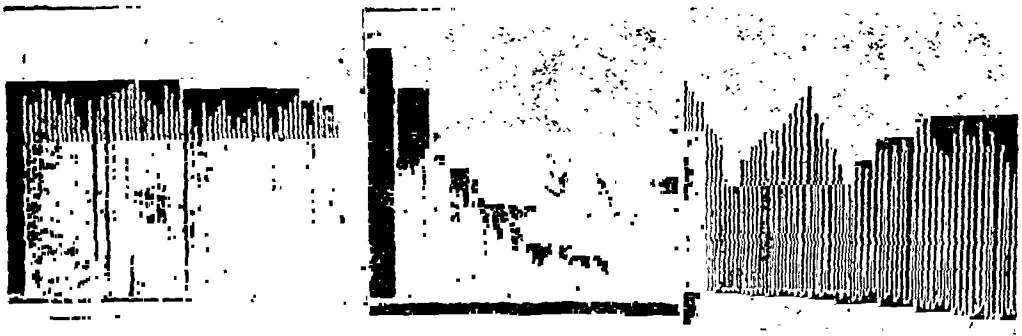

Fig. 5.—Fatigue of accommodation: Normal at sea level (left hand record); rapid fatigue at 22,000 feet in rebreathing test (middle record), and variations occurring 1.3 minutes later, subject breathing normal air (right hand record).

Fatigue of convergence has been studied with Howe's ophthalmic ergograph. Normal three-minute runs as controls were made without the low oxygen tension effect; then three-minute runs with approximately the same time interval were made in the low-pressure chamber and on the rebreathing apparatus. The findings on the rebreathing apparatus and in the low-pressure chamber showed a more rapid onset of fatigue than occurred with the controls. At 15,000 feet and at 20,000 feet the fatigue was marked, as was the case with accommodation. Here also the administration of oxygen caused a rapid return of converging power.

RETINAL SENSITIVITY

It is important that the retina be normally sensitive to light impressions, especially for those men who must fly at night, notably bombers and fliers doing patrol duty. A test for the contrast sensitivity of the retina has proved most useful and practical for our work, and only men who have normal sensitivity in this respect will be selected for night flying.

In this laboratory, tests to determine the threshold sensitivity of white and colored lights and for contrast are conducted in the following manner:

The Reeves wedge is made of two pieces of glass at a known angle, between which is run a solution of gelatin and neutral dye. The wedge is calibrated in millimeters, which is translatable into the percentage of light transmitted.

To test the threshold sensitivity to light, the subject is placed 20 feet from a spot of light, 3 mm. in diameter. Holding the wedge before the right eye, he slowly draws the slide from its cover, and as the light just disappears, a reading is taken. This reading is in millimeters and is then translated to percentage of transmission.

The threshold for color is taken the same as the foregoing, red and green lights, which are practically monochromatic, being employed.

The test of contrast sensitivitiy is made with a Reeves wedge and Reeves contrast square. The contrast square is made by placing a square of dark gray paper on a larger square of lighter gray, there being thirteen perceptible differences between the two papers. An illiterate "E" with the same perceptible differences is used as a check of the findings. This is lighted by a 75-watt nitrogen daylight lamp at a given angle and distance from the test object, and the subject is placed 20 feet in front of the object. The reading on the wedge is taken just as the contrast between the squares disappears. The average readings taken with the contrast sensitivity square gives 3.4 mm., and the illiterate

"E" 3.2 mm. To date, the normal for the light threshold of thirty-five subjects is 6.5 mm. The threshold for colors is: red, 4.4 mm., green, 3.7 mm.

Under the rebreathing test the threshold for light has shown an improvement in 25.9 per cent.; 44.5 per cent. show neither improvement nor falling off, and 29.6 per cent. show a falling off in sensitivity.

In the study of the threshold for colors, the red and green both show a falling off in 71.4 per cent., and neither a gain nor a loss in 28.6 per cent.

In former tests with a blue light, which was not absolutely monochromatic, there was improvement in 66.6 per cent. and falling off in 33.4 per cent.

CONCLUSION

In spite of the fact that the tests made in the laboratory are influenced somewhat by the psychologic elements of excitement, concentration, etc., still, we have found very sensitive and definite ocular reactions under the conditions to which the airman is subjected. The changes in the eye (one of the most delicate of the peripheral sense organs) are due mainly to the want of oxygen, and not to the many other suggested conditions, such as lowered blood pressure, decreased atmospheric pressure, carbon monoxid, nervous strain, and vibration of the motor. In our experience, the administration of oxygen prevents the occurrence of the untoward symptoms; but when these symptoms have occurred through its want, oxygen quickly restores the functions to normal.

VI. INFLUENCE OF ALTITUDE ON THE HEARING AND THE MOTION-SENSING APPARATUS OF THE EAR*

E. R. LEWIS, M.D. (Dubuque, Iowa)
Lieutenant-Colonel, M. C., N. A.
Mineola, L. I., N. Y.

The middle ear mechanism is normally adjusted to transmit sound vibrations in either direction. Ordinarily this apparatus is largely occupied in transmitting sound vibrations from without inward. The membrana tympani is set into vibration by impact of vibrations transmitted by the air in the external auditory canal, and the ossicular chain carries the vibrations across the tympanic cavity to the footplate of the stapes, which, with its annular ligament, fills the oval window. The perilymph there receives the impact, and owing to the venting action of the internal drumhead of the round window, this incompressible fluid is enabled to take up the vibrations and distribute them by way of the saccule and cochlea in such a manner as to bring about interaction between the sensory cells of Corti and the tectorial membrane. This stimulation causes these cells to emit nerve impulses which are translated in the sensorium into hearing.

Whereas the conformation of the auditory canal, tympanic cavity, saccule, scala tympani, and scala vestibuli is such as to facilitate delivery of most of the incoming vibrations to the cells of Corti, the petrous bone conducts a certain amount of the incoming vibrations away from their ultimate cochlear distribution.

Any obstruction in the path of these vibrations determines an increase in the conduction of sound vibrations away from the Corti cells, and the volume of such afferent vibrations is directly proportionate to the amount of obstruction.

Sound vibrations are also conducted to the tympanic cavity by way of the bony structures of the skull, and a certain amount of such vibrations are conducted away from Corti's cells by way of the ossicular chain, membrana tympani and thence the air in the external auditory canal.

By utilizing certain uniform sound stimuli applied in the form of standard tests and observing responses, it is possible to determine the normality of sound conduction and sound perception; also the general character of certain abnormalities of sound conduction and sound perception.

The motion-sensing mechanism of the internal ear is situated within an intricate physical instrument, the utricles and semicircular canals; one half of this physical instrument is housed in the right petrous bone, the other half in the left. Motion to which this instrument is subjected is immediately participated in by the fluid contained within it and brings about an interaction between the hairs of the sensory cells of the cristae and the cupula surmounting them, causing stimulation of these sensory cells and emission of nerve impulses, which are translated in the sensorium as sense of the body being in motion. A certain quotum of these impulses originating in the cells of the cristae are distributed as motor impulses to the extra-ocular muscles, causing involuntary movement of the eyes.

By utilizing certain uniform motion stimuli applied in the form of standard tests, and observing responses in a certain standard manner, it is possible to determine the normality of motion perception of this apparatus, and of eye movements resulting from stimulation of the cells of the cristae; also the general character of certain abnormalities of motion sensing and of eye movements.

Without going into the details of standard tests of the cochlear and vestibular (or motion-sensing) portions of the ear, which would entail a discussion too voluminous for presentation in this connection, it may be briefly stated that experiments have been conducted with a view to determining the effects of altitudes on each of these ear functions. In these experiments, both the Henderson rebreathing apparatus and the decompression tank types of artificial altitude have been utilized.

It has been determined that the hearing function shows no deterioration attributable to impairment of the perceptive element (stimulability of the Corti cells) prior to attaining a degree of altitude that causes acute general functional impairment of all the higher cerebral sensory and psychic centers. This condition is signalized by the onset of semiconsciousness or unconsciousness.

During ascent from a denser to a rarer atmosphere, the sound-conducting apparatus may show transitory interference with function attributable to expansion of air incarcerated within the eustachian tube, tympanic cavity or air spaces of the mastoid resulting in inequality of intratympanic and extratympanic air pressures. As adjustment of these air pressures occurs by venting through the eustachian tube, interference with function of the sound-conduction apparatus ceases.

Such disturbances are much more marked during rapid descent, when the discrepancy between intratympanic and extratympanic air pressure becomes very marked. Cases have been observed in which the extratympanic pressure was so great as to cause perforation of the drumhead. Practically all cases showed congestion of the drumhead following rapid descent. Occasionally the irritation and congestion resulting from rapid changes of altitude have been observed to cause acute otitis media.

---

*From the Medical Research Laboratory, Air Service, Mineola, L. I.

Observations on the effects of altitude on the motion-sensing function of the ear have revealed nothing in the nature of obtunded ability to perceive motion or alterations in eye reactions to motion stimulus. Certain individuals showed greater inability to tolerate motion stimulus at 16,000 to 18,000 feet than they had shown at the accustomed altitude, as evidenced by the onset of nausea and vomiting. This, however, may be regarded as indicative of the onset of altitude sickness (ordinary "mountain sickness") rather than of altered vestibular function.

VII. EFFECTS OF LOW OXYGEN PRESSURE ON THE PERSONALITY OF THE AVIATOR*

STEWART PATON, M.D. (Princeton, N. J.)
Major, M. R. C., U. S. Army
MINEOLA, L. I., N. Y.

The effects of diminished oxygen supply on the personality cannot be explained until the results of the reduction on the functions of different organs have been made known. Until this information is gathered, our views on this subject are based to a great extent on a review of clinical data, illustrating some of the changes of temperament and character of the aviator taking place in the effort to adjust the organism to high altitudes.

Before reference is made to a few of the symptoms already noted, it is desirable to remind the reader of the fact that the problems involved in the study of any personality are not merely psychologic, but should include the biologic analysis of the reactions of the entire organism, considered as a living unit. It is extremely important that this point of view should be appreciated and accepted by the investigator. A personality study is a great deal more than a mere psychologic analysis, and often the correct interpretation of emotional and mental reactions is to be sought in the solution of some complex biologic problem.

Among the more frequent phenomena associated with reduced oxygen pressure is an increased irritability of the reflexes, particularly noticeable in very active knee-jerks. Sometimes there is a reduction of the knee-jerk, due to an apparent hypertension of the muscles and an inability to relax them. In these cases reinforcement is necessary in order to bring out the knee-jerk. This evidence of increased muscular tension in connection with the aviator is an interesting phenomenon, and deserves careful consideration. Probably impulses from the higher cortical centers are responsible for this interference with the tendon reflexes. In order to facilitate the study of these reactions it is desirable that the capacity of the aviator to relax his muscles should be tested before as well as after flying. The muscles to be tested should include those of the face, head and neck as well as the arms, legs, hands and feet. In some cases the increased tension seems to be localized. An aviator who is capable of relaxing his limb muscles may show a very tense condition of his facial muscles, or vice versa. The mental tension is reflected in many different ways. Those who suffer from the effects of reduced oxygen supply generally give some indication of this trouble in their facial expression. Varying degrees of anxiety may be represented, ranging all the way from the indefinite expression, accompanying the ill defined consciousness that some impossible task or unpleasant experience is impending, to a state of mind indicating that well formulated ideas play an important rôle in the disturbance, causing not merely apprehensiveness but also an anxiety in which intellectual processes have become active determining factors. In the indefinite states of apprehensiveness and ill defined anxiety the reactions correspond to the conditions described by the French as *angoisse*, a condition in marked contrast to the one described as *anxiété*, in which the disturbances of the higher mental responses are more strikingly in evidence than are the bulbar symptoms, marked by disorders of the circulatory, respiratory and other physiologic systems.

The occurrence of specific sensations of pain are indicative of local disorders, but the evidences of bodily and mental distress and the varying degrees of discomfort and unpleasantness evoke a variety of symptoms. Not infrequently these signs of imperfect adjustment to life in the air are intensified by conflicting trends: one a desire to continue in the Air Service and the other a consciousness of not being equal to the task. The failure of the aviator to face the dilemma squarely and settle the conflict definitely invariably leads to complications often ending in a serious loss of nerve and morale.

Mental disturbances of this character occurring as the result of lowered oxygen supply at times become sufficiently accentuated to suggest the beginning complex associated with an anxiety psychosis. In addition to the emotional disorders there is generally a very slight incoordination of the finer muscular movements, and often a marked fine tremor of the fingers and tongue.

It is interesting to note that from time to time clinicians have suspected the occurrence of some defect in the amount of oxygen supplied in connection with the various forms of anxiety neuroses. Using a form of treatment based on empiricism, attempts have been made to remedy this condition. The French clinicians for some time have recommended that oxygen be administered in these neuroses; and one or two different forms of apparatus for giving the oxygen by subcutaneous injections have been used with varying degrees of success.[1] The amount of pain accompanying the injections and the difficulty in perfecting the technic have been the chief objections to the use of this method of treatment. Heckel[1] says the method of administration that he has devised obviates these defects.

Unquestionably the administration of oxygen to a person who has been subjected to an experimental test or has ascended to a high altitude in a plane is followed by a number of interesting reactions, which have not received the attention they deserve.

We have noted that the character of the dermagraphia in a person who has been deprived of oxygen changes completely after oxygen has been inhaled for one or two minutes. The blotching character of the red line noticeable in states of fatigue, as well as following a period of reduced oxygen supply, disappears after the inhalation, and the puckering of the skin and clear edges of the line suggest that a decided improvement in the vascular tone has taken place.

THE OCCURRENCE AND SIGNIFICANCE OF B. WELCHII IN CERTAIN WOUNDS*

JAMES L. STODDARD, M.D. (Boston)
Captain, M. R. C., U. S. Army
France

It is well known that *B. welchii* is usually very common in early wounds. Studies by Fleming[1] in 1914-1915 showed its presence in 81 per cent. of 127 wounds from one to seven days old; in 34 per cent. of fifty-six wounds of from eight to twenty days, and in 18.5 per cent. of wounds more than twenty days old. Goadby[2] presents figures for the occurrence of anaerobes in wounds, but none for the incidence of *B. welchii* in particular. He found a markedly less percentage of saccharolytic and ensporing anaerobes in excised than in nonexcised wounds. Plisson[3] found harmless persistence of *B. welchii* until the tenth day in twenty-two of 186 cases, and in three beyond the fifteenth day. Taylor[4] proved the presence of gas-forming bacilli on sequestrums in 14 per cent. of a series of wounds with sequestrums aged from forty-five to 300 days.

Taylor's figures show that *B. welchii* can occur and persist for a very long time on bone and in deep parts of wounds. Whether cultures from the exudate would be positive in these cases is a different question. Taylor considers the persistence to depend on the protection of the bacteria from the body fluids; hence it seems improbable that the bacilli would appear in the exudate taken by the usual cultural methods.

Since the observations recorded here were made partly to discover as far as possible the significance of the usual cultural examination of wounds for *B. welchii*, cultures were taken by the routine methods, which consisted in (1) taking specimens of the exudate on cotton swabs; (2) planting in recently boiled and cooled milk of neutral reaction, and (3) anaerobiosis by the pyrosoda method of Wright or by the hydrogen and palladium asbestos method. Milk is not quite so good a cultural medium for *B. welchii* as glucose bouillon, for it takes a slightly heavy inoculation to get growth. It is used, however, because it is the only practicable method of getting a characteristic culture in twenty-four hours, and hence is the usual routine test. No culture method gives growth with doses under a certain size; hence the absolute presence or absence cannot be ascertained in any event.

The points especially considered here are: (1) the occurrence of *B. welchii* (as determined by the usual culture test) in wounds at a base hospital during a quiet period when casualty clearing station treatment is thorough; (2) the occurrence of gas infection in the same series and its relation to the occurrence of *B. welchii;* (3) the persistence of *B. welchii* after gas infection, compared with its persistence in wounds in which no gas infection has occurred; (4) the value of examination for *B. welchii* in regard to the diagnosis of cases of gas infection occurring in excised wounds, and (5) the relation of *B. welchii* to suture.

THE OCCURRENCE OF B. WELCHII IN WOUNDS AFTER THOROUGH CASUALTY CLEARING STATION TREATMENT

It seemed probable that a quiet period would afford an opportunity to determine the effectiveness of casualty clearing station treatment, when at its best, in reducing the occurrence of *B. welchii* in wounds. During the time of the study, a culture was taken of each wound at the first dressing or soon after, of patients arriving at the hospital. Only wounds involving muscles were included. Trivial wounds and clean bullet wounds were eliminated. A consecutive series of 137 cases was thus obtained.

B. welchii was proved present by culture in 23 per cent. of the cases. Of nineteen wounds of one day, *B. welchii* occurred in 26 per cent. Of forty-four wounds of two days, it was found in 20 per cent.; in twenty-seven wounds of three days, in 19 per cent.; in thirty-five wounds of from four to seven days, in 25 per cent., and of four wounds of from eight to ten days, in 50 per cent. Eliminating the figures for eight to ten days as based on too few cases, the occurrence is markedly uniform in wounds of the different ages.

The occurrence of the same or a higher incidence in older cases is explicable by the fact that these patients came late to the hospital, largely because they had unusually severe wounds or had had a previous gas infection at the casualty clearing station. In view of the persistence of *B. welchii* after gas infection (described later), the incidence was calculated in wounds that had not had a previous gas infection. The incidence for wounds up to four days remained the same, but for wounds of from four to seven days it fell from 25 to 16 per cent., and for the whole series from 23 to 19 per cent.

Smear examination was done merely to obtain a rough idea of the numbers of *B. welchii* present. As a rule, only two distinctions were made: (*a*) those having no *B. welchii* or extremely few, so that a considerable search was necessary to find them; these are called negative; (*b*) those having more; these are called positive.

The incidence of cases with positive smear and culture (eliminating cases with previous gas infections) was: in one day wounds, 18 per cent.; in wounds of two days, 18.6 per cent.; in wounds of three days, 8 per cent.; in wounds of from four to seven days, 11 per cent., and in the series as a whole, 14.5 per cent.

These low percentages for the occurrence of *B. welchii* seem to indicate extremely effective previous treatment. The influence of excision at first seems to be absent, for of the cases in which excision was performed, according to the field medical card, *B. welchii* was present in 23.5 per cent., while of those not stated to be excised it was present in 19.4 per cent. The explanation lies in the fact that the more severe wounds are the ones that are excised and are also the ones in which *B. welchii* is most likely to occur. Eliminating cases with previous gas infection, the occurrence of *B. welchii* in the excised wounds is not lower than in the nonexcised. These results suggest, at least, that good judgment was used in performing excision, giving a very uniform output of cases.

---

[4] Taylor, K.: Persistence of Bacteria within Sequestra, Ann. Surg., 1917, 66, 522.

Goadby's finding of a higher percentage of saccharolytic anaerobes in nonexcised than in excised wounds has only the appearance of differing from these figures. His nonexcised cases included nearly all cases at a period when excisions were little done, while his excised wounds occurred at a different period when the percentage of excisions was high. Consequently each of his series included wounds of all sorts, while in this series the nonexcised were merely the lighter wounds left over after the severe ones had been done.

INCIDENCE OF GAS INFECTION IN THE SERIES

Definite muscle gas infection after arrival occurred in the series in 2.9 per cent. of the cases. If a few slightly doubtful cases are included, the total is 5.1 per cent. Of the cases with *B. welchii* on culture, unquestionable gas infection occurred in 13 per cent.; including slightly doubtful cases, the figure becomes 22.5 per cent.

THE PERSISTENCE OF B. WELCHII IN THE WOUNDS

The cases in which *B. welchii* was found were followed, as far as possible, until the cultures became negative. Usually more than one negative examination was obtained. Besides the cases in this series, records are included from a previous series of 200 nonconsecutive cases.

In the cases without gas infection, a fairly marked change from positive to negative was evident by the eighth day of the wound. Before this, 30 per cent. had become negative; but after this day, only 17 per cent. remained positive, and these for a short time, as a rule.

Of the cases with gas infection, the period of change from positive to negative cultures was not evident until about the twelfth day of the wound; before this, only 12 per cent. had become negative; while afterward, 36 per cent. remained positive.

Thus there is evidently a greater tendency for the persistence of *B. welchii* in wounds having muscle infection. This is in spite of the fact that each case of gas infection had thorough removal of débris and excision, and in each case the symptoms of an active infection stopped immediately after the operation. Even if the reckoning is made from the time of the operation as a starting point, the period of change comes on the tenth or eleventh day. The persistence was remarkable on casual observation before the figures were obtained.

A persistence in noticeable numbers in smears occurred in the gas infection series until about the eighth day of the wound. There seemed to be a fairly regular diminution in numbers until the eighth day, and 43 per cent. had become negative by that time, while 20 per cent. remained positive beyond the eighth day. In the cases without gas infection, more than 75 per cent. had become negative before the eighth day, and only 15 per cent. remained positive beyond it.

These figures indicate the tendency to persist longer in moderate numbers when a gas infection has preexisted. In fact, in wounds without gas infection the tendency is strong for bacilli to become very few early in the history of the wound. Half of the smears had become negative by the fifth day, while by that time only 18 per cent. had become negative on culture. Of the gas-infected cases, however, only 12 per cent. of the smears had become negative by the fifth day, and none by culture.

These results suggest that *B. welchii* does not flourish long in surface exudate. The time of persistence in gas infection cases, with the gradual diminution in numbers, suggests either foci of infection, gradually overcome, superficial growth in the exudate, or a gradual exudation of the bacteria from the previously infected tissues. Local foci of active infection seem extremely unlikely in view of the thorough operation in each case, and the entire absence of clinical evidence of infection. A superficial growth in the exudate might account for the early persistence in considerable numbers; but the long, late persistence in numbers practically imperceptible in the smear suggests rather gradual riddance of the bacteria from the infected muscle. Such a process would also account for the large numbers soon after operation. Pathologic studies show the presence of *B. welchii* beyond the area of apparent infection, and it is often easy in cases of heavily infected wounds to demonstrate the passage of bacteria from within the infected wall.

The marked tendency to early dying out in numbers in cases not infected is additional evidence of the difficulty of the continued growth of *B. welchii* in surface exudate in open wounds. There are always a certain number of cases of slight local gas infections which are not noted clinically. It seems probable that this must account for a certain number of the instances of persistence in the cases classified as not infected. This makes the probable true persistence in moderate numbers very small. The later persistence in very small numbers is probably to be explained by the presence of small foci, such as pockets, in which favorable anaerobic conditions are obtained; it is most noticeable in very large wounds which are apparently quite open, but in which, on account of the magnitude of operation, it is difficult to carry out a complete excision or removal of débris.

THE VALUE OF EXAMINATION FOR B. WELCHII

It is apparent on examination of the slides that in cases of active gas infection, bacilli are usually present in much larger numbers than in wounds of the same age without gas infection. Thus, of the wounds of from one to three days with *B. welchii* on culture but without gas infection, 40 per cent. showed negative smears; 46 per cent showed very moderate numbers, and only 4 per cent. showed fairly large numbers. Of the gas-infected cases (twenty in number), 5 per cent. showed negative smears, 40 per cent. moderate numbers, and 55 per cent. large numbers. Thus the finding of large numbers of *B. welchii* in well excised wounds of from one to three days seems strong presumptive evidence of active gas infection. (It may be remarked that of these particular gas-infected wounds, practically all had been excised.) The older the wound, the stronger the evidence.

If the cultures are positive but the smears negative, or if the cultures are negative, it is somewhat strong evidence against gas infection. It is not at all conclusive evidence, for in certain cases of gas infection, *B. welchii* may be absent altogether. In other cases, in which *B. welchii* is a factor, the infection may begin about a foreign body deep in the wound and the culture be negative. It does not seem likely that these cases make as much as one fifth of the cases of gas infection.

If moderate numbers occur, the evidence is of little more value than is obtained by culture alone.

The presence by culture alone reduces the chances from 1:30 against a given wound in this series being gas infected to 1:7, and hence is so slight evidence to be hardly worth considering.

It should be emphasized that these figures apply only to wounds of the special character described. It seems probable that in wounds before excision or when excision is not carefully done, neither smear nor culture can afford very valuable evidence on account of the common occurrence of *B. welchii.*

RELATION TO SUTURE

Of nine cases with *B. welchii* on culture at time of suture, two were failures, developing gas infection, and one a part failure. Of the remainder, *B. welchii* persisted, with positive smears, harmlessly for various periods after the suture; in two cases it persisted for three days; in one, for four days, and in two, from one to two days. One case of positive culture was obtained five days after suture. The two cases of failure were in wounds of from one to two days, and large numbers of *B. welchii* were present in each case. In no successful case were more than very moderate numbers present at the time of suture. As far as the evidence of this small number of cases goes, it does not seem that the mere presence of *B. welchii* is a contraindication for suture, but that its presence in large numbers is. In none of the cases were streptococci present. The significance of the presence of *B. welchii* may be entirely different when associated with various organisms.

SUMMARY AND CONCLUSIONS

1. In a consecutive series of 137 wounds aged from one to eleven days, in patients arriving at a base hospital during a quiet period after thorough casualty clearing station treatment, *B. welchii* was obtained by culture in 23 per cent. Cases with more than extremely few *B. welchii* organisms on smear made 14 per cent. of the series. These figures are much lower than for wounds during rush periods, or for wounds before excision was common.

2. The small difference in the occurrence of *B. welchii* in the series in the excised, compared with the nonexcised, is due to good judgment in excising especially the wounds in which *B. welchii* is most apt to be present.

3. Definite muscle gas infection occurred in 2.9 per cent. of the series. Including slightly doubtful cases, the incidence is 5.1 per cent. Of the cases with *B. welchii* on culture, the cases with unquestionable infection number 13 per cent., and including the slightly doubtful cases, 22.5 per cent.

4. For further studies, cases of gas infection were included from a previous nonconsecutive series. These were practically all in excised wounds. It was found that the cultures for *B. welchii* tend to become negative by the eighth day when no gas infection has occurred, but to last until the twelfth day or later in the cases with gas infection. Even reckoning the day of operation as the starting point, persistence is distinctly greater in the gas-infected wounds. This is in spite of complete lack of evidence of active infection after the thorough operation performed in each case.

5. There is a definite tendency to persist in greater numbers until the eighth day in the gas-infected cases than in those not infected.

6. In cases without gas infection, the numbers of bacilli tended to become very small early in the history of the wound.

7. The results suggest that *B. welchii* does not flourish long in surface exudate. Persistence in cases without gas infection is probably due largely to previously unrecognized local infection, or to small anaerobic foci in large wounds in which a thorough excision was impracticable. The persistence after gas infection may be explained by a gradual riddance of the bacilli from invaded but not definitely altered tissues.

8. In wounds of the character of this series, the presence of *B. welchii* in large numbers is good evidence of an active gas infection. The evidence is stronger, the older the wound. Its absence is strong but not conclusive evidence of lack of infection, for negative cultures are occasionally obtained when *B. welchii* is not a factor in the infection, or when the infection begins deep about a foreign body.

9. If moderate numbers of *B. welchii* are present, the evidence is of about the same value as is given by culture alone. The value of culture alone is so slight as scarcely to be worth considering.

These facts with regard to the value of smear and culture with reference to the diagnosis of gas infection in these wounds appear to rest on the inability of *B. welchii* to grow luxuriantly for a long period on the surface of surgically cleaned wounds, thus preventing the occurrence of large numbers when no infection is present; and on the occurrence of large numbers of *B. welchii* in the exuded serum of the infected cases, thus causing the highly positive smears.

10. The statements made here probably do not apply to wounds that have not had thorough previous surgical treatment.

11. The presence of *B. welchii* in large numbers was a contraindication to sutures in the small series observed. Its presence in small numbers is not necessarily a contraindication. There are points here in connection with the association of bacteria that need investigation. *B. welchii* may persist harmlessly as long as five days after suture.

"Team Work" by the Medical Profession.—In a summary of that portion of the Cavendish lecture by Sir Bertrand Dawson relating to the future of the medical profession, the *Medical Officer* quotes him as having said that the growth of knowledge makes measures for the prevention and cure of disease more and more complex, so that the full exercise of these powers no longer lies within the scope of individual effort but requires for its accomplishment well organized "team work." In the future, investigation will become more and more technical and collective treatment correspondingly specialized. This renders the patient's home less suited for his treatment and the need for institutional facilities all the greater. Sketching the scheme which he would consider best for fostering a closer union between the health organization of the community and the intellectual and professional life of the doctors, he said that the nucleus of this system of medical service would be the hospital. Local hospitals and clinics would be grouped in relation to central and teaching hospitals in the larger towns, and there would be corresponding relationship between the local practitioner and the consultant of the district. From this it would follow that the practitioner's source of income would be more in the nature of a salary than of fees, but this would not mean the extinction of private practice. A full-time salaried service for all medical men he regarded as detrimental to the best interests of both doctor and patient, for medicine stereotyped under such a system would become a "soulless machine."

BLOOD TRANSFUSION AT THE FRONT AREA *

BENJAMIN I. HARRISON, M.D. (Cleveland)
Lieutenant, M. R. C., U. S. Army
FRANCE

This paper is based on observations of transfusions of blood performed at advanced hospitals. The patients were those having but little prospect of recovery otherwise.

Donors.—Arrangements were made through the medical officer, with the sergeant in charge of the walking wounded, to supply lightly wounded men for donors. As the occasion required, those selected were sent to the resuscitation ward for grouping and charting. A grouped list of all donors was available at a minute's notice, day or night. A list of about ten donors, usually assigned to light duty around nearby wards, was kept at all times. As economy we used Group II, III and IV men. Some casualty clearing stations use only Group IV donors, and do not group their patients; however, we found that it required about ten minutes to group a patient, and thus, we were able to use all donors excepting the group I men.

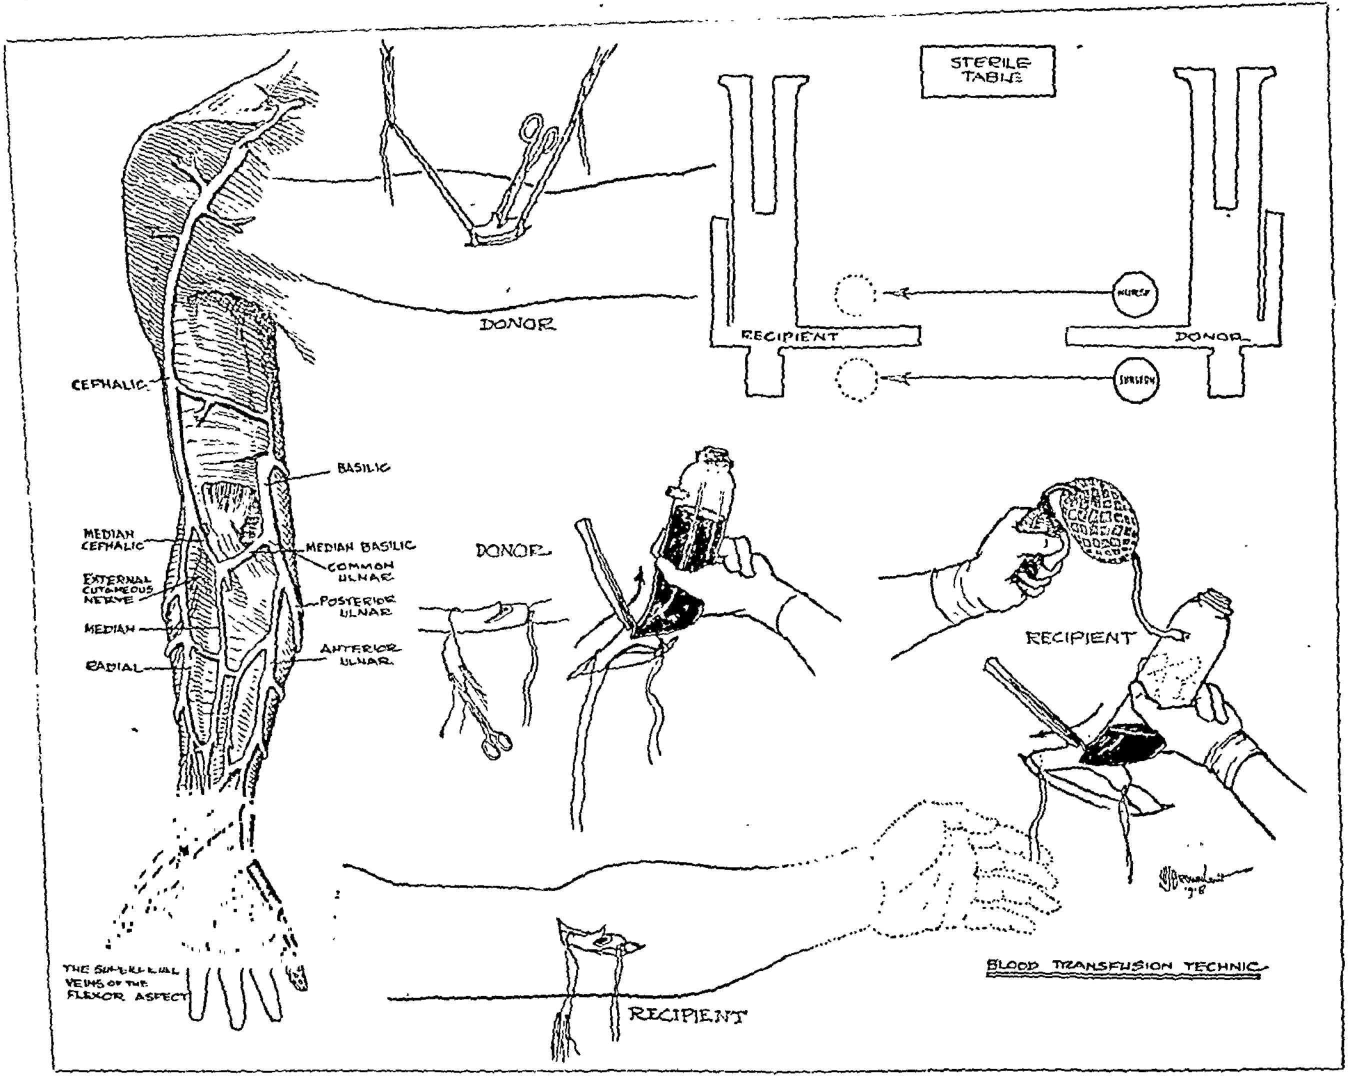

Fig. 1.—Technic of blood transfusion.

Grouping.—The selection of donors and the grouping of recipients was done by the method described by Lee,[1] with serums and necessary equipment furnished by Captain Karsner.[2] By holding the slide over a candle, the reactions were judged with the naked eye. All cases were classified without difficulty. The technic was so simple that it could be carried out in the resuscitation ward, proving very practical from all points of view.

Technic of Transfusion.—The indirect method of transfusion was used, with the technic as shown in Figure 1. The tubes were coated with ordinary hard paraffin obtained from the pharmacy at the casualty clearing station.

A vein of the flexor aspect of the arm was used, 3 c.c. of 1 per cent. procain being used for infiltration anesthesia. The proximal end of the donor's vein was tied, and the distal end of the recipient's, a ligature loop being placed around the distal end of the donor's vein and the proximal end of the recipient's. Traction by means of a hemostat closed the veins.

* From No. 9 (Lakeside, U. S. Army) General Hospital.

[1] Lee, R. I.: A Simple and Rapid Method for the Selection of Suitable Donors for Transfusion by the Determination of Blood Groups, British Medical Journal, 1917, 2, 684.

[2] Karsner, H. T.: Transfusion with Tested Bloods, Including the Grouping of One Thousand Bloods and a Method for Use at Advanced Hospitals, The Journal A. M. A., March 16, 1918, p. 769.

In our series of cases, there was not an instance of coagulation in the tube. The average time for filling each tube of 300 c.c. capacity was three minutes; for the entire transfusion, approximately thirty minutes.

Differential Diagnosis—Hemorrhage and Shock.—From a clinical point of view, it is very difficult, in some cases, to know whether a patient is suffering from hemorrhage, from shock, or from both. In the three conditions, the pulse, the blood pressure and the collapse are not dissimilar. In hemorrhage, however, the patient is generally restless and anxious or worried about his condition. A shock patient, on the other hand, is inclined to be listless and apathetic. In extreme cases of shock, the patient is almost invariably of a grayish-blue color, this symptom being attributed by Crile to a failure of internal respiration.

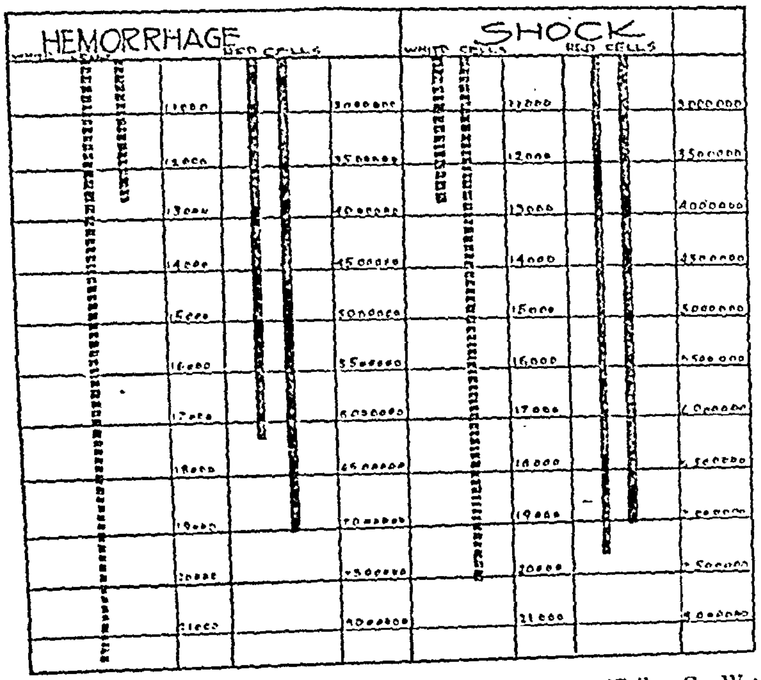

Fig. 2.—Blood counts in shock and hemorrhage. (Crile, G. W.: Hemorrhage and Transfusion, p. 111.)

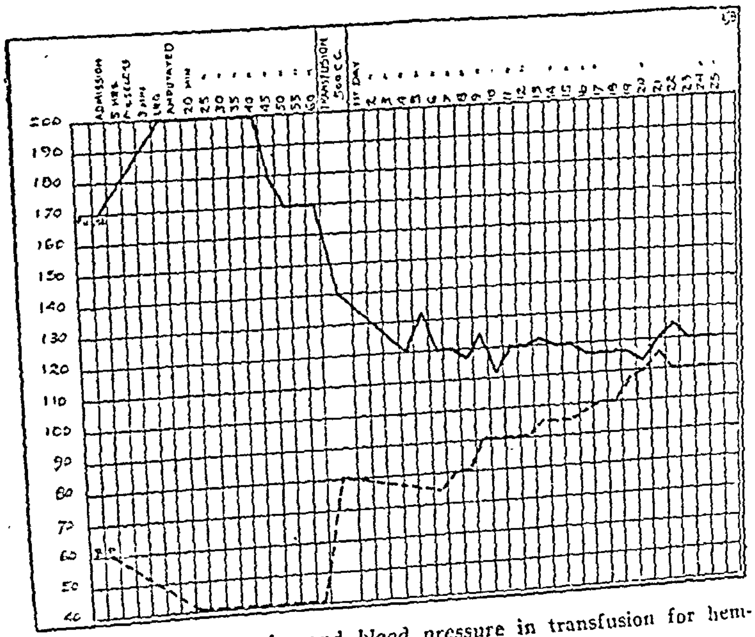

Fig. 3.—Curve of pulse and blood pressure in transfusion for hemorrhage.

As a practical measure, I would suggest that a note be made on the field card by the medical officer at the field ambulance, indicating the amount of hemorrhage.

Increase of White Blood Cells in Hemorrhage.—In hemorrhage, we found a definite increase in the white blood count, confirming the observation of Crile.[3] However, our series showed a blood count, in severe cases, amunting to 45,000. In shock, on the other hand, we found no increase in the white blood count. Nearly all our cases were examined under eight hours after injury (Fig. 2).

Transfusion for Hemorrhage.—In acute hemorrhage, transfusion of blood is specific, provided the patient has not been in an exsanguinated state long enough to cause irreparable injury to the brain. The effects generally are striking, immediate and permanent. In our series, we had only one case in which transfusion was useless, owing to this fact.

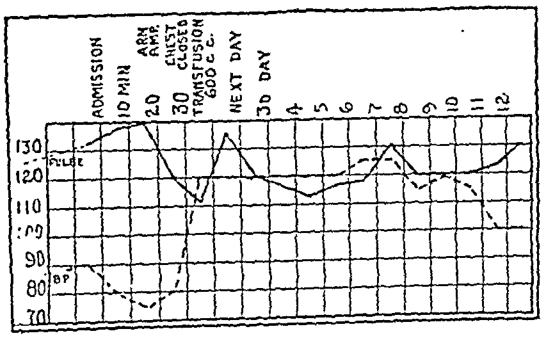

Fig. 4.—Curve of pulse and blood pressure in transfusion for shock and hemorrhage.

Transfusion of blood is followed by a marked rise of blood pressure, increase in pulse volume with slowing of rate, while respiration returns to normal (Fig. 3).

Transfusion for Hemorrhage and Shock.—In cases in which there was both hemorrhage and shock, transfusion proved effective, but the results were not as good as those following transfusion for hemorrhage alone (Fig. 4).

Transfusion for Shock.—In shock without hemorrhage, if the patient had not yet reached the gray-blue stage, a certain amount of benefit followed transfusion of blood—a change often sufficient to carry through operation to recovery. If, however, the patient *had* reached the gray-blue stage, no benefit resulted from transfusion (Fig. 5).

In a series of fifty transfusions, in cases in which recovery by the usual course was *not* expected, 55 per cent. of the patients recovered. Two of the patients died of pneumonia. In several, with gunshot wounds of the abdomen, transfusion was of no avail. In a few of the most severe cases of gunshot wounds of the abdomen we gave 200 c.c. of blood three days in succession, following the primary transfusion. However, this treatment showed no more improvement than in those cases in which transfusion was performed at one séance, provided sufficient blood had been given at the primary transfusion.

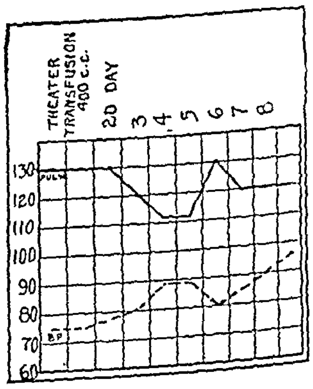

Fig. 5. — Curve of pulse and blood pressure in transfusion for shock.

Only once was there a slight reaction. This man underwent transfusion for hemorrhage from a severed

popliteal artery. Fourteen days later the leg was amputated. A severe hemorrhage followed the operation, so that the man was again transfused. On the third day, a slight rash, not unlike serum rash, had developed, accompanied by a temperature of 101 F. The following day the temperature was down to normal, and the rash cleared up without further disturbance.

CONCLUSIONS

1. Timely blood transfusion for hemorrhage is a specific cure.
2. For hemorrhage and shock, results are good, but not specific.
3. For pure shock early transfusion, that is, transfusion before the "gray-blue" stage is reached, is useful, and is the most efficient treatment. Transfusion in the gray-blue stage is of little use. In this class, no other treatment has been useful.

FURTHER EXPERIENCE WITH FACE MASKS *

GEORGE H. WEAVER, M.D.
CHICAGO

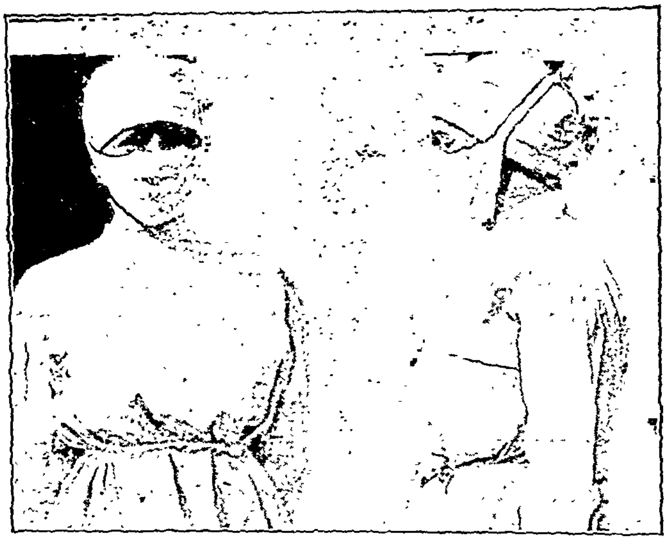
When the Durand Hospital of the John McCormick Institute for Infectious Diseases was opened, rigid aseptic technic was adopted and the nurses were specially instructed in measures calculated to protect them from infections. From March 12, 1913, to Nov. 1, 1914, nine out of sixty-nine nurses, or 13 per cent., acquired clinical diphtheria. From this time on, all nurses giving a positive Schick test were immunized with diphtheria antitoxin. This practically eliminated active diphtheria; but from Nov. 1, 1914, to June 1, 1916, weekly throat cultures disclosed ten diphtheria bacillus carriers among forty-three nurses, or 23.25 per cent.

Up to June 1, 1916, nine cases of scarlet fever occurred among 112 nurses who were on duty, or in 8 per cent.

As we were unable to explain so many instances of infection through faulty technic, an effort was made to eliminate a possible factor of danger that had previously been largely ignored, namely, infection through mouth spray. Since June 1, 1916, gauze masks have been used by the nurses, and up to Oct. 1, 1918, six diphtheria bacillus carriers have been detected among seventy-three nurses, or 5.2 per cent.[1] No case of scarlet fever has occurred since masks were worn. The nurses are instructed to change the mask as soon as it has been known to be grossly contaminated, and never to put the hands to the mask to adjust it, etc., until the hands have been thoroughly washed.

Early in 1918, bacteriologic tests showed that the masks we were using did not remove all the bacteria thrown out in mouth spray. The masks consisted of two layers of gauze, 28 by 24 mesh; but as they were worn only once before washing and resterilizing, shrinkage soon made the openings in the gauze much closer than they were in the new masks.

Studies were instituted to learn how the masks could be made most efficient. The results that we have obtained agree very well with those recently reported by Haller and Colwell[2] and Doust and Lyon.[3] They are here presented as serving further to emphasize the importance of gauze masks of proper composition. When the probable importance of droplet infection in the dissemination of human tuberculosis attracted attention, gauze masks to be worn by the patient were advocated. Hamilton, in 1905, advised the use of gauze masks to cover the mouth of patients with scarlet fever when there were severe streptococcal complications and when the individual could not be properly isolated. In 1916, Meltzer advocated the use of a fine mesh net over the faces of patients with infantile paralysis and also over the faces of attendants. Various mechanical protections of the face were formerly used by physicians when swabbing throats and doing tracheotomy in cases of diphtheria. Gauze masks have been long used by many surgeons and their assistants with the purpose of protecting wounds from infection by mouth droplets.



Durand hospital mask, devised by Miss Charlotte Johnson, superintendent: The gauze (44 by 40 mesh) is cut 8 inches wide and 23 inches long. The sides and one end are turned down one-quarter inch. It is folded twice, the unturned end first, making a 7½-inch square. The opposite diagonal corners are cut off 1 inch and the raw edge is turned in one-half inch. It is stitched firmly all around. A 1-inch dart 1½ inches long is taken up at the middle of each side of the mask. A 14-inch tape is sewed on the opposite uncut corners. This mask has the advantage of covering the nose and mouth and in making the traction on the chin and not drawing on the nose and lips.

Our experiments were performed in a quiet room with no currents of air. It was assumed that the power of various gauzes to filter moist spray from air would increase with closeness of mesh and with the number of layers employed. In the first tests a spray of carbolfuchsin was employed, the dye being susceptible of fairly accurate measurements. It was thrown as spray by a hand atomizer. Briefly, these tests showed that the percentage of fuchsin passing through the gauze becomes progressively less as the mesh of the gauze becomes closer and as the numbers of layers of gauze is multiplied.

[1] Our experiences up to Dec. 1, 1917, were reported by Weaver, G. H.: The Value of the Face Mask and Other Measures in Prevention of Diphtheria, Meningitis, Pneumonia, etc., The Journal A. M. A., Jan. 12, 1918, p. 76.

[2] Haller, D. A., and Colwell, R. C.: The Protective Qualities of the Gauze Face Mask, The Journal A. M. A., Oct. 12, 1918, p. 1213.

[3] Doust, B. C., and Lyon, A. B.: Face Masks in Infections of the Respiratory Tract, The Journal A. M. A., Oct. 12, 1918, p. 1216.

Similar tests were made by throwing a spray of a suspension of *Bacillus prodigiosus* in salt solution against gauze and estimating the number of colonies developing on plates exposed on the opposite side. It was found that the number of colonies became progressively less as the mesh of the gauze became finer and as the number of layers of gauze increased. It was noted that at a distance of from 3 to 5 feet from the spray, the proportion of the bacteria reaching that point which passed through the gauze barriers was greater than at shorter or greater distances. This is probably to be explained by the more rapid precipitation of the larger particles as regards the nearer distances and by the failing force at greater distances. These results demonstrated that gauze will remove bacteria from air when carried in a moist spray. The efficiency of the gauze as a filter is in direct ratio to the fineness of mesh and the number of layers used.

Further tests were now made to determine the efficiency of gauzes of various meshes and in different numbers of layers as filters for mouth spray. A suitable subject for these tests was found in an adult who was affected by a chronic antrum and ethmoid suppuration with constant purulent discharge, in whose throat and mouth *Streptococcus viridans* in abundance was constantly present. It was found that a mouth spray very rich in bacteria was discharged by this patient when the cheeks were distended with air and then, the lips being suddenly opened a little, the air was forced out with an explosive puff. The spray produced in this way was more abundant than that following coughing, and the driving force was greater, thus furnishing a very severe test as to the filtering power of obstructing gauze. Tests were made by having the patient direct such forcible expiratory efforts toward vertically placed Petri dishes containing blood agar at a distance of 6 inches, the face being uncovered and covered by various gauzes in different multiples. The results shown in Table 1 were obtained on a day when the streptococci were especially abundant. The colonies developing on the plates after twenty-four hours in the incubator were practically all of *Streptococcus viridans*. It will be noted that the coarser gauze allowed a large proportion of the bacteria to pass through, even when six layers were interposed. On the contrary, the finer gauzes removed many more of the bacteria, and when six and eight layers were used, almost all the bacteria were held back.

TABLE 1.—NUMBER OF COLONIES OF STREPTOCOCCUS VIRIDANS DEVELOPING ON BLOOD-AGAR PLATES EXPOSED AT 6 INCHES TO TWO EXPLOSIVE EXPIRATORY EFFORTS IN WHICH THE CHEEKS WERE FIRST DISTENDED WITH AIR AND THEN THE LIPS FORCED SLIGHTLY APART WITH A PUFF

There appeared to be no appreciable difference between dry and moist gauze in filtering properties. Since three or four layers of gauze with a mesh of 44 by 40 removed most of the bacterial spray thrown with unusual force at a short distance, further tests were carried out to learn how efficient as filters of mouth spray three layers of this gauze would be when placed over the mouth of the person discharging the spray and over the exposed plate at varying distances, corresponding to the face of the person in the neighborhood. The plates were placed vertically as in the preceding experiment. The expiratory effort consisted of two strong coughs with the lips slightly parted.

Tables 2 and 3 show the results of two such experiments, similar ones with slight variation being secured many times. The same person served in these tests as those reported above. When the gauze mask was over the face, very few colonies developed in the plates. When the gauze was over the plates, the proportion of colonies as compared to unobstructed plates was also small, but slightly larger because here the

finer particles are dealt with. At a distance of 2 or 3 feet, relatively more of the particles reaching that distance pass through because here only very fine particles are projected. In the cases in which *B. prodigiosus* was smeared over the pharynx and tongue, fewer colonies developed in plates placed behind gauze obstruction. This is probably because the bacteria were less thoroughly distributed in the saliva. If the colonies that develop on unobstructed plates placed near the month are examined under magnification, it is noticed that many are compound colonies; and many of those that develop from the larger particles of saliva are the result of the growth of clumps of bacteria. Thus the number of bacteria removed is greater than the number of colonies would indicate. These larger particles of saliva are probably more dangerous, not only because they contain more bacteria but also because the toxic substances contained in the projected mucus may act on the mucous membrane where they lodge so as to favor the growth and penetration of the associated bacteria. Since the completion of these studies, the masks used in Durand Hospital have been made of three layers of gauze with a mesh of 44 by 40. The nurses are instructed to wear two superimposed masks, making six layers of gauze, when caring for cases of virulent infections in which secretions are abundant. The gauze that we have used is absorbent. It is probably preferable to buttercloth, which is treated to make the material nonabsorbent. Particles of mucus will adhere more quickly and firmly to the absorbent material, as the rapid removal of the water leaves a thicker and more sticky residue. So far we have been able to secure but one weave of buttercloth, about 28 by 30, and this is not as fine a mesh as is desirable. Even this is very difficult to find, most large dealers having none in stock and usually not knowing where it can be secured. In any case the dressing is removed in washing. Our experience with masks has been principally confined to their use to protect attendants on the sick from infection. They have been used not only by nurses, but also by physicians in their work while taking cultures from throats, doing intubations and examining chests. The mask on the face interferes with putting the hands to the mouth and nose, and so indirectly becomes a source of safety to the individual, whose hands are apt to be contaminated in her work and who thoughtlessly may put them to the face. We have also used masks over the faces of mothers while nursing their babies, when either one has been infected by diphtheria or has been a diphtheria carrier.

The employment of gauze masks over the face to prevent the transfer of infections to others was thoroughly worked out and practically applied by Capps[4] at Camp Grant. He used masks to prevent cross-infections in ambulances and in the admission rooms and wards of the hospital. Similar use of masks has since been generally adopted in Army and Navy camps and in many civil hospitals. The intelligent use of gauze masks and other measures may be instituted equally well in private families. Many family epidemics might be limited by such means. In all instances in which infections locate in the respiratory tract and in which the infectious agent is discharged in mouth spray, it is reasonable to protect those about the patient by masks of gauze.

The present concentration of effort to limit droplet infection should not prevent an equally energetic effort to close other channels of spread of infectious materials. The use of face masks may serve to give an unwarranted feeling of security to those employing them if they neglect the measures that prevent carriage of infectious materials through other agents. Emphasis must still be placed on proper sterilization of eating utensils, destruction of all infectious discharges, avoiding all contamination of foods, and special care regarding the washing of the hands every time the sick are handled.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

PNEUMOCOCCUS VACCINE (See N. N. R., 1918, p. 337-8).

A vaccine or "antigen" is prepared by E. C. Rosenow (THE JOURNAL, March 16, 1918, p. 759) by digesting a suspension of pneumococci at 37 C. until about 95 per cent. of the organisms have become gram-negative and the mixture is relatively nontoxic to guinea-pigs.

Actions and Uses.—(See N. N. R., 1918, p. 337-8.)

E. C. Rosenow believes that the protective power against pneumococcus infection is greater with a vaccine prepared according to his method than that of a vaccine made according to the usual method.

Eli Lilly & Co., Indianapolis.

Pneumococcus Antigen (Rosenow), Lilly.—Marketed in 5 Cc. vials, each Cc. containing 20 million partially autolyzed pneumococci.

Bacterial Examination of Green Vegetables.—Kurk (*Am. Jour. Pub. Health,* September, 1918) undertook an investigation to determine the presence of the coli-typhoid group of organisms, streptococci and anaerobic organisms on green vegetables. Samples were purchased at various stores about Chicago, one sample of watercress being obtained from a glass bowl containing water from a free lunch counter in a saloon. The culture mediums were made according to the standard methods of water examination of the American Public Health Association. Five organisms superficially resembling paratyphoid bacilli were isolated, but in no case did complete cultural and agglutination reactions determine that they belonged to this group. *B. coli* were found in twenty-two out of twenty-nine samples. Of samples from twelve stores classed as clean, eleven showed *B. coli;* of ten samples from stores classed as fair, six showed *B. coli,* and of six from dirty stores five contained *B. coli.* Streptococci were found on three samples—two from clean stores and one from a store classed as fair. *B. cloacae* were found on five samples, three from dirty stores and two from fair stores. A sample of green onions contained a great number of *B. cloacae,* as did a later sample of onions obtained from the same store. Mold spores were found on thirteen of twenty-nine samples; twenty-eight out of twenty-nine samples contained gas formers on lactose broth. The total bacterial count at 37 C. and 20 C. varied widely, the former from 6,000 to 4,300,000, and at the latter temperature from 18,000 to 25,800,000, the latter count being obtained from the sample of watercress from the saloon free lunch. Other than this the sanitary condition of the store did not seem materially to influence the bacterial count.

SERUMS AND VACCINES IN INFLUENZA

With respect to serums and vaccines in influenza, there are certain simple facts and considerations that physicians will do well to keep in mind at this time. The main point to keep always in sight is that unfortunately we as yet have no specific serum or other specific means for the cure of influenza, and *no* specific vaccine or vaccines for its prevention. Such is the fact, all claims and propagandist statements in the newspapers and elsewhere to the contrary notwithstanding. This being the case, efforts at treatment and prevention by serums and vaccines, now hurriedly undertaken, are simply experiments in a new field, and the true value of the results cannot be predicted by any one. Indeed, the exact results can be determined if at all only after a time, in most cases probably not until the epidemic is past and all the returns fully canvassed. Consequently the physician must keep his head level and not allow himself to be led into making more promises than the facts warrant. This warning applies especially to health officers in their public relations.

As to serum treatment, the only noteworthy new method so far is the injection in severe cases of influenzal pneumonia of the serum of patients who have recovered from such pneumonia.[1] The principle of this method is rational; analogous procedures have given seemingly good results in scarlet fever and other diseases; and the results reported in influenzal pneumonia appear promising. Further trial of this treatment under proper conditions consequently seems to be warranted. It should be borne in mind, however, that McGuire and Redden[1] made their observations in the declining phase of the epidemic when the organism or organisms concerned appeared to be losing virulence. For this and other reasons the expectations as to what may be accomplished by this method must be kept within reasonable bounds. Influenza is a self-limited disease with variable complications and of variable severity in different places, thus offering great difficulties in the way of evaluation of different methods of treatment.

At least two kinds of vaccine are in use in the hope that they may have preventive effects. One consists solely of killed influenza bacilli, and it is being extensively used in the East. We have as yet no decisive figures as to its effects, but there is an impression that it may have some value. The other vaccine is a mixed vaccine of the more important bacteria in the respiratory tract in influenza, principally pneumococci, streptococci and influenza bacilli. It appears that vaccines of this nature are in extensive use, but we have no evidence that any benefit will be derived from them. To say that thousands have been vaccinated with apparently good results means nothing at all simply because we are still in the midst of the outbreak, in many places even in the earlier stages. How slender the basis for this anti-influenzal vaccination when it is considered that the real nature of influenza is still unknown! In any event, it will require many carefully elaborated and controlled observations before anything definite may be learned in regard to the effect of these vaccines, and it is probably safe to say that nothing on which to rely in the future can be learned from the indiscriminate vaccination now going on. There is, therefore, no basis on which promise of protection from vaccines may be made. They may be harmless, and they may or may not be of preventive value.

MEDICAL ASPECTS OF AVIATION

The subject of rotation tests employed in examining aviators for their sense of balance has recently been debated[1] in The Journal by the critics and the supporters. Whether or not these tests are too strict, it is at least clear that the flying men should have not only good general health, but also keen vision, quick reactions, coolness, and normal or more than normal capacity for maintaining their equilibrium.

In this issue appears a series of papers[2] showing the work that is being done to protect aviators against the effects of altitude, low barometric pressure, and deficiency of oxygen. This is a matter that has steadily increased in importance from both the medical and the military standpoints. The rapid improvements in aeroplanes under the stimulus of military needs have made it possible to carry aerial fighting to greater and greater altitudes. Speed and its equivalent, the ability to climb above the opponent, is to air fighting very much what the windward position, or weather gage, was in naval warfare in the days of sailing ships. Accordingly, even the bombing and observation planes are now able to fly for hours at altitudes of 12,000 and 15,000 feet, as they must do in crossing the enemy line; while the pursuit or battle planes fly at the enormous altitudes of 18,000 and 20,000 feet and even more. Everything depends on these hawks of the battle field, and it is they that protect their own observation planes, or in a swift swoop drop down on and destroy the observation planes of the enemy.

[2] Medical Studies in Aviation, pp. 1382-1400.

With the increase in the altitudes at which flying is common, there has been a corresponding increase in the development of so-called air staleness among pilots. It is particularly the most experienced aviators who succumb to this disorder and become unable to fly longer at the necessary altitude. This is, of course, a matter of the utmost military importance, as it deprives the service of its best aviators. Air staleness is a condition in some respects like the irritable heart of the overstrained soldier, or like overtraining in the athlete. To what extent such conditions are functional or neurotic or dependent on some abnormality of chemical balance is a problem that is now under active investigation both in America and in England in military hospitals for cardiac patients. Individual predisposition toward air staleness is subject to wide variations, and it is a matter of great importance, therefore, both for the avoidance of loss of life among the men in training for our air service, and for the development of the highest military efficiency among those selected, that the capacity of every candidate to withstand the effects of altitude and deficiency of oxygen should be determined.

The investigators at the Medical Research Laboratory at Mineola have found not only the theoretical but also a highly practical solution for this problem. By means of the rebreathing apparatus introduced by Henderson for this purpose, the subject breathes a closed volume of air and thus consumes the oxygen. The exhaled carbon dioxid is absorbed by alkali. By the reduction in the amount of oxygen, the subject is exposed to progressively lower tensions of oxygen, and thus to the physiologic equivalents of greater and greater altitudes until the limit of his endurance is reached.

During the low oxygen test, continuous observations are made on the arterial pressure, pulse and breathing, on the sounds and size of the heart, on alterations of vision, particularly stereoscopic and peripheral, and on the development of mental instability and muscular incoordination. The peculiar response of the cutaneous blood vessels known as the tache cérébrale (a concomitant of various nervous and cerebral diseases) likewise occurs in a considerable proportion of the men undergoing the test, and tends to indicate unsuitability.

The results obtained show that a considerable percentage of the men who pass even the exacting medical examination required by the Aviation Service are unable to withstand altitudes even as low as 10,000 feet without exhibiting such physical or mental depreciation as would seriously endanger a man piloting a plane. On the other hand, these tests reveal a small percentage of men who are naturally so resistant to low oxygen that they can withstand the equivalent of 20,000 feet or more for a half hour or longer without serious depreciation, either mental or physical. Evidently such men are specially fitted for work at high altitudes.

Nor is the usefulness of these tests ended by the enlistment and grading of the pilot. The Medical Corps is assigning to each aviation unit one or more flight surgeons, assisted by physical directors selected from among the men who were formerly trainers of college athletic teams. It is their duty to keep the aviators in as perfect physical condition as if they were so many football players. The flight surgeons are all given a special course of training at the Medical Research Laboratory of the Air Service in the physiology, or as it has now become, the medicine of altitude.

Previous investigations, such as those of the Pike's Peak Expedition,[3] have demonstrated that the acclimatization of persons living at various altitudes involves certain functional readjustments, especially an increased number of red corpuscles, a decreased alkali reserve in the blood, and a larger volume of breathing, that is, a lowered alveolar carbon dioxid. These readjustments, however, require days or even weeks to develop, and the study of the condition of aviators has demonstrated that unfortunately the brief periods during which they are exposed to low oxygen result in no appreciable degree of acclimatization. On the contrary, repeated flights at altitudes above those which the individual's unacclimatized (i. e., sea level) functional capacity can easily compensate act like repeated nervous and cardiac overstrains. If too often repeated, air staleness results, and the pilot is either incapacitated to fly at all or, if he persists, he is liable to lose consciousness in the air and fall.

The rebreathing test finds its use, therefore, as a means of diagnosis, for it now becomes possible, whenever the flight surgeon suspects that air staleness is developing in one of the men in his charge, to determine accurately the degree of overtraining. Furthermore, it appears[4] that the use of this low oxygen test may have a broader application in internal medicine as a measure of the functional power of the heart and circulation.

The application of physiologic knowledge to this problem appears likely to prove one of the most valuable contributions to the efficiency of the American Air Service.

THE CONGENIAL CALORIES OF THE CANDY SHOP

At a time when conservation of foodstuffs, and especially of sugar, is one of the vital necessities of our country and the fundamental duty of every one of us, the soda-guzzling youngsters and the candy-nibbling matinée followers are properly looked on with suspicion. There is no doubt that before the war our consumption of soda water, ice cream and confectionery was growing at a rapid rate, and there is every reason to believe that when the restrictions are removed and the prices abate, these typically American habits will continue as before, or increase. Just how large an amount of nutriment is taken in this way by many people is probably not generally appreciated, and formerly we had no definite information on which to base an estimate. This has now been furnished in a reliable and exact form from the Nutrition Laboratory of the Carnegie Institution.[1] By aid of the method of direct determination of the heat of combustion in the calorimetric bomb, the total calories furnished by numerous popular sweets and beverages have been ascertained. These analyses reveal that an ordinary six-cent (war price) bar of sweet chocolate will furnish ordinarily 200 or 300 calories. Taking most of these chocolate candies sold in bar form, whether sweet, milk or nut chocolate, ten cents will purchase as high as 735 calories in some brands, ordinarily from 300 to 600 calories, and in only a few cases less than 200 calories. As 500 calories is nearly one third of the basal caloric requirement of normal man, and may represent from one fifth to one sixth of the total daily requirements of the average man not at severe muscular labor, a bar of chocolate candy, or its equivalent from the bonbon box, means a very considerable addition to the food supply which is usually a between-meals addition that does not materially curtail the food eaten at each meal. No wonder there are so many fat women at the matinée.

America's most prominent inventions in the line of beverages are undoubtedly the cocktail and the ice cream soda. What amount of fire the former provides, the Benedicts do not state; probably the calorimetric bomb could not do it justice anyway, for a calorimetric bomb is a soulless thing, without a particle of poetry or imagination. But a cold and clammy ice cream soda apparently digests readily in the alimentary apparatus of the bomb, and registers from 202 to 467 calories, depending on the liberality of the soda clerk. There seems to be some honesty in the soda trade, for the fifteen centers give more calories than the ten centers. The "sundaes" or "college ices" furnish a large fraction of a full meal, yielding generally from 300 to 500 calories. When you order a nut sundae you get from 4 to 6 gm. of protein to help balance the ration. And the children's favorite, the ice cream cone, comes through with about 100 calories for a nickel. So it isn't surprising or undesirable if Willie doesn't eat all of his dinner when he has had two ice cream cones, a bar of chocolate almonds and an ice cream soda. He has had about a thousand calories in the mess, which is about one third as many calories as father needs for a day's work.

Even the simpler beverages furnish numerous calories. Ginger ale gives about 150 calories to the pint, and grape juice about twice as much. The plain vanilla or chocolate soda without cream averages about 200 calories. Ordinary "crackers" furnish about 4.5 to 5 calories per gram, which means that the usual soda cracker gives about 30 calories, or about one-tenth to one-fifteenth as much as ten cents' worth of chocolate candy, although it does provide much more protein. So the afternoon tea, with candies and fancy crackers, furnishes not a few calories, usually to people who do not seem to need them very much. At a boys' school it was found that the between-meals candies, sodas, etc., amounted to about 640 calories, which is a mere trifle in the nutrition of the adolescent male. We are tantalized by the statement that at Vassar these extras totaled 10 per cent. of the daily intake—we long for the details. Physicians will see in these figures reason for careful inquiry into the sweet-tooth requirements of his patients, as well as the meal-time consumption of foods—especially in the fat ones.

PEANUTS AND SOY BEANS AS HUMAN FOODS

The evolution of food products from animal sources—the production of meat, milk, eggs, pork, bacon, poultry, etc.—involves the conversion of plant products, many of which may serve directly as human nutriment. This transformation of cereals, for example, into meat and milk, is an expensive one from the standpoint of the energy exchange that is necessitated. To build up one pound of food in the form of animal tissues calls for the feeding of many pounds of nutrients from plant sources. It has therefore become a serious problem in the face of a possible shortage to determine to what extent it is permissible, not to say profitable, to convert edible cereals into animal products prior to using them rather than to consume the corn, barley, wheat, etc., directly in the human ration. Milk must be had at all events; but it seems probable that both Americans and Europeans will tend more and more in the next few years to displace meat and related animal food materials to a considerable degree with vegetable foods. The trend toward a more extensively vegetarian regimen is almost certain to follow as a consequence of the altered conditions of animal husbandry enforced by the high cost of feeds.

The prospect thus presented brings the cereals into prominence at once. Among a large group of the population in France, bread constitutes more than half of the energy intake per day. The cereals are essentially alike in being comparatively low in their content of protein as contrasted with animal foods. Any plan to supplant the latter to any extent in the dietary therefore calls for the introduction of products from vegetable sources that can be classed as protein-rich. These must be available to supplement in some degree the already indispensable cereals, just as meats and other animal foods do at present.

---

[1] Benedict, Cornelia G., and Benedict, F. G.: The Energy Content of Extra Foods, Boston Med. and Surg. Jour., 1918, 179, 153.

The protein problem is not, however, merely a quantitative one. There is considerable justification for the belief that the proteins supplied by meat, eggs and milk are of high biologic value. In replacing them as the status of the pocketbook and the economics of agriculture seem to demand, attention must be centered on the possibility of securing proteins that represent a suitable amino-acid make-up, the nutritive significance of which has repeatedly been pointed out in The Journal. The legumes, particularly the ordinary garden peas and beans, come foremost into mind as protein-rich vegetable food materials. But there is no lack of evidence to show that while the proteins of the more widely used legumes are quite well utilized by the human body, comparing very favorably in this respect with the cereal proteins, they are not as completely utilized as the proteins supplied by such animal foods as meats, eggs and milk.

Two leguminous seeds have lately made better claims for more popular recognition in human nutrition. The soy bean has been a staple for generations among the people of China and Japan. It forms a prominent source of protein in their diet, supplementing rice, which is so extensively used and contains a great excess of carbohydrates. These people keep few live stock and eat little meat. Apparently they believe it is the part of economy to eat vegetables rather than to feed them to animals and then eat the animals. In this country a beginning in the use of soy beans in the human dietary has scarcely yet been made. The second legume, the peanut, is popularly known, though its prominence dates back to scarcely more than half a century. It is eaten in a casual way, rather than as a staple in the diet; and it would not be difficult to gather "impressions" as to the poor digestibility of the peanut.

We have already presented some reasons for believing that both the soy bean and the peanut may represent unusually desirable sources of protein. In reporting the feeding experiments of Osborne and Mendel[1] and Daniels and collaborators,[2] the favorable prospect offered by an increased use of both products was intimated. Further studies conducted by Johns and his co-workers at the Bureau of Chemistry in Washington show that from both soy beans and peanuts it is possible to isolate a liberal quantity of proteins relatively rich in their yield of the amino-acids lysin and tryptophan—a partial index of presumable nutritive superiority.

An added test of dietary value—that of digestibility—has been furnished anew by the Office of Home Economics in the United States Department of Agriculture. Holmes[3] has conducted this investigation on men in whose diet soy bean and peanut flours contributed a liberal proportion of the entire protein intake. They were eaten in the form of a well-known type of "quick bread" or "biscuit" as a part of a simple mixed diet. None of the subjects reported any digestive or other physiologic disturbances. Holmes is justified in believing that the figures, 85 per cent. for the digestibility of soy bean protein and 86 per cent. for the digestibility of peanut protein, indicate a very satisfactory utilization of these proteins by the human body. No attempt was made to ascertain the limit of tolerance for soy bean and peanut flours when included in a simple mixed diet; but since in seven experiments with soy beans the subjects ate an average of 70 gm. daily of soy bean protein, and in four experiments with peanut flour the subjects ate an average of 65 gm. of peanut protein daily without any observed symptoms of physiologic disturbance, it should be evident that these proteins are tolerated by the human body in amounts in excess of those that are likely to be found in the ordinary mixed diet. At any rate, the figures obtained for the digestibility of the proteins supplied by soy bean and peanut press-cake flours compare favorably with those obtained for cereal proteins, and are somewhat higher than those obtained for some other legume proteins. Perhaps, therefore, we shall not go amiss for the present in classing dietary articles suitably prepared from either the soy bean or the peanut as substitutes for both wheat and meat. The success of such substitution, however, becomes a problem of the culinary art rather than of physiology.

Points on Treatment of Bone and Joint Injuries at the Front.—Early splinting; early definitive surgery; early closure; early function through voluntary movements; early appreciation of the best functional position for stiffened joints: shoulder should be fixed in 70 degrees of abduction; elbow at a right angle or even a little less; wrist dorsally flexed; hip abducted 5 degrees, outwardly rotated 10 degrees, flexed 20 degrees; knee, for standing occupation, flexed 20 degrees; for sitting, 30 degrees; ankle with the foot at right angles with the lower leg. Joints in these positions, though completely ankylosed, can be counted on to preserve much useful function for the limb. Immobilization in these favorable positions should be insisted on in the presence of any process or lesion which threatens ankylosis.—*Review of War Surgery and Medicine.*

Current Comment

THE PROBLEM OF ESSENTIAL TEACHERS IN MEDICAL SCHOOLS

Since the entrance of the United States into the world war, several problems have arisen, the solution of which was necessary in order that the medical schools might be kept going and the regular supply of physicians maintained. First came the necessity of keeping medical students at their studies, which was met by establishing the medical enlisted reserve corps. Next came the question of the premedical students, for whom, as noted last week,[1] provision is now made in connection with the Students' Army Training Corps. A third and more serious problem, however, was how to hold at their teaching duties an adequate number of teachers. When the appeal for medical officers was made, many teachers patriotically responded who might better have remained at their college work. In some medical schools the proportion of teachers who entered the government medical services was so great as to endanger the very existence of the institution. This problem has been met by establishing in the Office of the Surgeon-General a list of essential teachers based on lists furnished by the deans of the well-recognized medical colleges. The policy of the Surgeon-General is not to issue commissions to a physician who is on the essential list unless notified by the dean that he has been released. There has been much discussion regarding some form of government recognition of those on the essential list, but no satisfactory method has been found. However, the fact that a physician is listed by the War Department as an essential teacher is a recognition of his teaching ability. Furthermore, the reservation of a physician as an essential teacher is equivalent to assignment to military duty. This is especially so now that medical schools are largely under government control and since the teachers are training students who, as members of the Students' Army Training Corps, are soldiers on active duty in the United States Army. Meanwhile, with this understanding it is believed that essential teachers will be willing to remain loyally at their teaching duties to which they have been assigned. If the student soldiers are to become well-trained medical officers, it is necessary that efficient methods of teaching in the medical school shall be maintained.

THE IMPOSSIBILITIES OF STRAW BREAD AS FOOD

As the indigestible parts of plants are to a large degree composed of complex carbohydrates, the best known of this group being cellulose, it has often been proposed to attempt to convert them into simpler carbohydrate compounds, like the sugars, which are more readily assimilated by the organism. Cattle and other food-producing animals can apparently utilize the "crude fiber" of plants to some extent, possibly through the intervention of the microbiotic agencies in the large gastro-enteric tract of the herbivora; but it would unquestionably be a nutritive gain if a more available product could be prepared from the resistant food residues. As cellulose, pentosans, etc., they serve primarily as "roughage" in the diet; once transformed into absorbable products, they might function just as starch and sugars do. The chemical possibilities here concerned have appealed to conservation enthusiasts in war time to the extent of suggesting the inclusion of chemically treated fibrous products like straw even into the ration of men. Fortunately we are in a position to profit in dietetics as well as in warfare by the mistakes of our enemies. It is reported on the authority of Professor Rubner,[1] the Berlin physiologist, that efforts were made in Germany during the hard winter of 1916-1917 to introduce the chemically treated straw, which experiment had shown to be well utilized by horses and cattle, as a diluent into the bread of the population. Rubner's investigations burst the bubble of possibility in this direction. Whatever may be the value of chemically treated straw in the alimentary tracts of herbivora, it is of inferior use in those species, such as the pig and the dog, with a less complexly constituted digestive canal. The further obviously probable indication of the unsuitability of the treated straw for the purposes of human nutrition has also been verified by Rubner. In the case of the dog, at least three quarters of the straw product remained unabsorbed. In the experiments on man, the addition of such straw to bread led to an increased waste, which was actually greater, in calories, than the energy value of the straw ingested. The straw bread was inferior in every way. Its palatability and texture were bad; it tended to develop distress in the bowel. These were the observations on healthy persons. What the less vigorous might have experienced can only be conjectured. Straw bread was "made in Germany," and we want none of it in America.

VOLUNTEERS FOR U. S. PUBLIC HEALTH WORK

The present epidemic of influenza has made it necessary for the United States Public Health Service to make an urgent call on physicians for help in localities in which the epidemic is unusually severe. A notice of this appeal appeared in The Journal two weeks ago and has been accorded gratifying response. That notice, however, was for more or less permanent position with the Public Health Service. On another page[2] is an appeal to physicians for temporary service. While those who volunteer for such service will not be in uniform, and while they will have no rank, this service is just as definite a patriotic privilege as is that of serving in the Medical Corps of the Army or Navy. This is especially true at this time when the need of the civilian population for a mobile supply of physicians is so great—for physicians who can be sent from place to place as exigencies require. Physicians who are able to serve in one of the proposed temporary appointments should waste no time in responding to this appeal of the United States Public Health Service.

RESPONSIBILITY FOR TYPHOID FEVER

The owners of steamers on the Great Lakes are warned by a recent decision of the federal district court that heavy money penalties may be exacted for illness caused by polluted water.[1] The damages awarded in eleven cases range from $305 to $16,045, totaling $50,462. In the case in question a lake steamer sailing from Detroit used impure water for drinking purposes after the water in the tanks aboard had been exhausted. The evidence submitted was held to prove beyond question that the typhoid cases were contracted by the drinking of this polluted water. The increasing rarity of typhoid fever in this country focuses attention on instances of this sort, so that more attention will doubtless be paid to safeguarding travelers against typhoid infection through oversight or negligence.

THE AMERICAN RED CROSS AND PUERICULTURE IN FRANCE

A goodly portion of the October issue of the *American Journal of Diseases of Children* is concerned with what M. Paul Strauss of Paris has designated as puericulture in France.[2] It bears witness to the splendid service in which the Children's Bureau of the American Red Cross is engaged. Any one who reads at all must have formed some conception of the serious situations created among mothers and children through the displacement of the population of northern France, the lack of medical attention owing to the scarcity of physicians, and the food and fuel crisis, added to the innumerable other deprivations that a country so cruelly invaded has experienced. In the city of St. Etienne, with a population of 180,000 before the war, there were 120 physicians; at present the 250,000 inhabitants depend on the medical services of fourteen physicians. Most villages have been without any since the mobilization. The Red Cross has shared in the management of the child *rapatrié;* it has devoted its best efforts to the reduction of infant mortality; it has promoted the clinics for prenatal care; it has not only given aid to prospective and present mothers and their nurslings, but also has facilitated the plans for protecting young women and promoting social hygiene. Educational work has been no small feature of the campaign. We should have difficulty in rivaling an exhibit of child welfare work such as was staged at Lyons with an attendance of more than 170,000 persons in three weeks. The story of the efforts of the American Red Cross to aid French agencies in uniting all available forces, governmental, philanthropic and medical, in a preventive educational program is inspiring. For us a more immediate lesson has been expressed by the chief of the Children's Bureau of the American Red Cross in France, Professor Lucas of the University of California. He says:

> What I have seen not only in France, but also in England and in this country since returning, has convinced me that now is the psychologic time to develop and coordinate all our child welfare work in this country. I feel that all the different associations which represent the best medical thought in child welfare should certainly get together on a definite coordinated program for this country, and back up our governmental bureaus dealing with child welfare problems. This year in America has already been proclaimed by President Wilson as the "children's year," and it will be a great lost opportunity unless some national program which coordinates all the best efforts both private and governmental is worked out and put on a very sound basis.

This is the psychologic time for many reforms.

Medical Mobilization and the War

Medical Women's Hospital Established

The American Women's Hospitals No. 1, cooperating with the American Committee for Devastated France and working with the Sixth French Army in the advanced area, is now established in a XV Century chateau near the front. Dr. Barbara Hunt, Bangor, Me., is the director of this unit.

More Units for American Women's Hospitals

The American Women's Hospitals has recently received from Mr. Gibson, special commissioner of the American Red Cross in France, a request for six units, each unit to contain ten medical women, ten nurses' aides, one dentist and four chauffeurs. The Red Cross will supply the nurses required for these units some of which will be placed, under a special arrangement with the French Service de Santé, in French military hospitals where they will care for the American and French wounded soldiers, while other of these groups will be used for refugee work. The first unit, composed of Chicago medical women, which will be known as the Chicago Unit, is already assembled, and one unit will be sent over every month until the entire six are accounted for.

Volunteer Physicians for U. S. Public Health Service Work

Two weeks ago we published an announcement asking for volunteers for permanent work as Acting Assistant Surgeons in the Public Health Service. In addition at the present time the Public Health Service is in urgent need of physicians for temporary duty in connection with the influenza epidemic. The service is organizing this work along state lines in connection with state boards of health. The Surgeon-General of the Public Health Service is anxious to have available physicians in various parts of the country on whom he can call for this temporary emergency work. The salary is $200 a month and $4 per diem allowance in lieu of subsistence. In responding, physicians should furnish the following information:

1. Will serve in his own locality?
2. Will serve in his own state?
3. Will serve in his adjoining states?
4. Will serve anywhere?

As the call is immediate and urgent, it is suggested that any physician who feels that he can do some of this work telegraph to the Surgeon-General, U. S. P. H. S.; Washington, D. C., indicating by number, as above, whether he will serve in his own locality, in his own state, in the adjoining state, or anywhere in the country. Or, if he desires to serve only in his own state he should telegraph to "Public Health Service Officer, care State Board of Health." The U. S. Public Health Service has such an officer in each state except Nevada.

Public Health Problems

A sixth course of lectures and discussions on "Public Health Problems Under War and After War Conditions," is being held in the Lecture Hall of the Royal Institute of Public Health, London, on Wednesday in October, November and December. The topics and speakers are as follows:

October 9.—"Anthropometry and *National Health.*" By Professor Arthur Keith, M.D., F.R.C.S.

October 16.—"Racial Reconstruction and the Proposed Ministry of Health." By C. W. Saleeby, Esq., M.D., F.R.S.Ed.

October 23.—"The Obviation of Ship-borne Infections." By W. M. Willoughby Esq., M.D.

October 30.—"The Prevention and Abortive Treatment of Venereal Disease." By Lt.-Col. L. W. Harrison, M.B., D.S.O.

November 6.—"Infection and Disinfection in War Time." By Professor J. M. Beattie, M.D.

November 13.—"The Tuberculous Soldier." By Miss Jane Walker, M.D.

November 20.—"The Care of Pensioners and Disabled Combatants in Relation to National Health and Wealth." By Sir John Collie, M.D., C.M.G.

November 27.—"National Kitchens and the National Health." By Alderman C. Spencer, Director of National Kitchens.

December 4.—"The Rôle of the Ports in the Protection of the Health of the Nation." By Professor E. W. Hope, M.D., D.Sc.

December 11.—"The Organisation and Administration of Child Welfare Centres." By G. Eric Pritchard, Esq., M.D., M.R.C.P.

December 18.—"The Proposed Ministry of Health." By Professor William R. Smith, M.D., D.Sc., LL.D., F.R.S.Ed., Sheriff of the City of London.

American Expeditionary Forces' Weekly Bulletin of Disease

The following paragraphs are taken from the *Weekly Bulletin of Disease*, dated September 23, issued for circulation among American medical officers in France:

Why Wait! Pneumonia Won't

Thin out billets and barracks before instead of after an epidemic has broken out. Whenever a command is thoroughly shot through with grippe or bronchitis or there has been an outbreak of diphtheria and simple sore throats, it is found possible as well as desirable to get more space for the men in barracks, even to the extent of putting them under canvas, and in every instance with most favorable results. Shelter tent existence beats a sick bed. Men living in the open in the bitterest weather are uniformly healthier and especially freer from respiratory infections than are men housed in the same climate. See if you can recognize any of the quarters of the men of your command in this description of billets copied from an inspection of a divisional training area.

The Experience of the American Expeditionary Forces with Respiratory Infections

By respiratory infections are understood to be those diseases which are passed by the moist discharges from the bronchi or trachea, the throat and the nose and mouth, namely, the spit, the saliva and spray. Of the diseases included in the nomenclature of the Sick and Wounded Reports of the American Expeditionary Forces the following eleven diseases are considered respiratory infections:

A	B
1. Mumps	1. Bronchitis (acute)
2. Measles	2. Influenza
3. Scarlet fever	3. Pneumonia (lobar)
4. Diphtheria	4. Tonsillitis (acute)
5. Meningitis (meningococcus)	5. Pneumonia (*broncho*)
	6. *Pharyngitis* (acute)

The order in which the two groups are listed above is the order for each group according to the number of days lost from hospitalization of each disease. The incidence rate for pneumonia per 100,000 troops parallels so closely the rate of the other diseases under consideration that the rate of this disease can best be used as a basis of comparison between the experience of the British Armies in France and that of the American Expeditionary Forces.

A.E.F.	1917	B.E.F.	A.E.F.	1918	B.E.F.
	January	8.67	392.3	January	17.18
	February	25.27	155.3	February	6.65
	March	14.58	163.9	March	10.11
	April	10.40	59.0	April	11.80
	May	8.93	16.5	May	7.65
	June	6.23	82.2	June	10.24
66.6	July	7.35	44.6	July	.....
26.9	August	4.88	40.7	August	.....
20.4	September	3.49			
70.21	October	5.88			
66.0	November	6.65			
213.3	December	7.55			

For pneumonia as for the other respiratory infections, here as in civilian experience at home, crowding and close personal contact and exposure while suffering from lowered resistance due to a variety of unfavorable conditions of occupation and environment are apparently the dominant and in many instances the sole determining factors in causing the serious increase of respiratory infections among our troops in France.

Of the 1,613,500 days lost in the American Expeditionary Forces up to June 1, 1918, from all causes, sickness, accident, injury in action and other traumatisms, 1,481,000 days, or 91.78 per cent., were lost because of sickness.

Of the total loss of days due to hospitalization from sickness, 631,226 days, or 42.61 per cent., were due to the eleven respiratory infections under consideration. The total case incidence of these eleven diseases by months from June, 1917, to August, 1918, has been as follows (A) and the rate per 100,000 troops with the American Expeditionary Forces as shown in B.

1917	A.	B.	1918	A.	B.
June	31	221	January	16,843	8,637
July	752	5,013	February	14,412	6,185
August	913	3,226	March	10,135	3,519
September	1,203	2,455	April	6,145	1,634
October	2,798	3,781	May	3,102	571
November	6,925	6,328	June	12,999	1,708
December	12,749	8,499	July	11,096	1,131
			August	12,457	969

The striking effect of the epidemic of influenza coming at a time of year when other respiratory infections are usually at their minimum is shown in the sudden increase in rate in June.

Memorandum for Battalion Surgeons

. . . Never forget, that in the final analysis, the prime and ultimate object of the Medical Department is to assist in the conservation and maintenance at the highest possible point of the fighting efficiency of the line troops. If the men become sick get them well by the best possible means and in the shortest possible time; if wounded, speed their evacuation to hospitals, where definite treatment may be given. Prepare them in every way, by every means available, in the front line stations for evacuation, get them back in the best possible condition. Hold malingerers to their work, but exercise judgment with the slightly ailing men; frequently two or three days' rest treatment in a field hospital will save to the service men with slight indisposition who, if held in the trenches might go on to a severe illness, or to a total loss. The condition in which men are received in the field hospitals from the front lines is always indicative of the efficiency of the men in the advance sectors. It has been noted that some of the diagnosis tags are not being properly made out and that even in the back areas they are often signed by enlisted personnel of the sanitary units. This is, of course, permissible in emergencies, but whenever possible diagnosis tags should be carefully looked over and signed by the medical officer.

Salvaging and Washing Gauze, as Practiced at a Base Hospital

The following method of salvaging and washing gauze, modified from methods in use in civil hospitals in the states, will save 65 to 70 per cent. of used gauze and bandages for reuse. By this method dressings and bandages can be rewashed many times. The process can be handled entirely by convalescent patients, with the supervision of one or two noncommissioned officers or enlisted men of the Medical Detachment who can also run the portable sterilizer:

(*a*) All dressings removed from wounds are saved, in G. I. cans, on surgical wards in dressing rooms, and in operating rooms. These are collected daily and taken to gauze salvage stations which stations should house a portable sterilizer to furnish steam for washing. (*b*) *Sorting.* On receipt at salvage station, dressings are sorted, gauze and bandages separated from cotton and other foreign bodies, all bandages and gauze are saved for washing, except gauze heavily loaded with boric ointment or picric acid. (*c*) *Rinsing.* The gauze and bandages, after sorting, are placed in a large concrete tank of cold water, which is frequently agitated, and changed twice in 24 hours. This is for the purpose of rinsing blood and pus from the dressings. (*d*) *Washing.* After rinsing for 24 hours, gauze is separated from bandages and washed, separately in an ordinary steam washer. If the revolving type is used, the gauze will have to be placed in cord bags, commonly used by steam laundries in washing collars. If the gauze is washed in a small washer of the "Dolly" type, it will not be necessary to place in cord bags. Wash each load one hour with live steam from sterilizers. (*c*) *Second Rinsing and Drying.* On removal from washer, they are carefully rinsed in tepid water and wrung through hand wringers by patients. They are then hung on lines out of doors to dry, or, in wet weather, are dried in a closed room that is heated by a stove. When nearly dry they are picked over and spread out in piles of equal size. (*f*) *Bulk Sterilization.* They are then sterilized in bulk for one hour, sent to the surgical supply room, sorted into small packages, and resterilized in autoclaves for use in operating rooms, dressing rooms, and for ward dressings. In civil hospital practice, in addition to the above, gauze is usually passed through a hypochlorite bleaching solution. In the present emergency, this step can be omitted without detriment.

Distinguished Service Crosses for Medical Officers

Announcement is made of the award of the Distinguished Service Cross to the following medical officers for the acts of gallantry described:

Capt. C. M. WILLIAMS, Medical Corps, Infantry (cannot identify) "For exceptional heroism in action on the Ourcq River, July 31 and August 1, 1918; northwest of Coulonges, France, August 2, 1918, and on the Heights, overlooking the Vesle River, August 3 to 7, 1918. During these three periods of severe fighting, Captain Williams maintained a dressing station close to the advanced lines and worked continuously night and day under heavy artillery and machine-gun fire."

First Lieut. HARRY S. WHEAT, Medical Corps, Infantry (Harry R. Wheat, Mrs. Mary L. Wheat, mother, 1911 Massachusetts Avenue, North Cambridge).—"For extraordinary heroism in action, August 16, 1918, from Sergy to Mont St. Martin, France, between the Ourcq and Vesle Rivers. During the attack on August 1, 1918, he went forward with the first wave and established a dressing station in an advanced position to render immediate aid to the wounded. On August 5, at St. Martin, after having been knocked down by the explosion of a shell and while under severe fire and machine-gun fire, he displayed exceptional coolness and devotion to duty in rendering surgical attention to others who had been wounded by the same shell."

Sergeant LEROY MORNINGSTAR, Medical Department Infantry, has been awarded the Distinguished Service Cross. "Sick, gassed and stunned by shells, he remained at his post of duty under heavy fire and bravely assisted the succoring of soldiers who had been injured near Vaux, France, July 1, 1918."

Private JAY LER ANTES, Medical Department, Infantry, has been awarded the Distinguished Service Cross, posthumously. "He fearlessly exposed himself to barrage and machine gun fire at Cantigny, France, May 28 and 29, 1918, to perform his duties as stretcher bearer in order that the sufferings of wounded might be relieved and lives saved with unselfish heroism. He left the security of the trench to go to wounded in a machine gun emplacement and while performing his noble duty was killed."

Captain CLAUDE A. MARTIN, Welsh, La., Medical Department, Infantry, has been awarded the Distinguished Service Cross. "He operated a battalion dressing station near Vaux, France, July 1, 1918, although the station was practically destroyed by shell fire."

Assistant Surgeon O. D. KING, attached to U. S. M. C.—"For extraordinary heroism in action near the Bois de Belleau, June 19, 1918. On two successive days the regimental aid station in which Surgeon King was working was struck by heavy shells and in each case demolished. Ten men were killed and a number of wounded were badly hurt by falling timbers and stone. Under these harassing conditions this officer continued without cessation his treatment of the wounded, assisting in their evacuation and setting an inspiring example of devotion and courage to the officers and men serving under him."

Passed Assistant Surgeon JOEL T. BOONE, U. S. M. C.—"For extraordinary heroism in action in the Bois de Belleau, France, June 19, 1918. On two successive days the regimental aid station in which Surgeon Boone was working was struck by heavy shells and in each case demolished. Ten men were killed and a number of wounded were badly hurt by falling timbers and stone. Under these harassing conditions this officer continued without cessation his treatment of the wounded, superintending their evacuation, and setting an inspiring example of heroism to the officers and men serving under him. On June 25, 1918, Surgeon Boone followed the attack by one battalion against enemy machine-gun positions in the Bois de Belleau, establishing advanced dressing stations under continuous shell fire."

Passed Assistant Surgeon WILLIAM T. GILL, attached to U. S. M. C.—"For extraordinary heroism in action near Vierzy, France, July 19, 1918. He established a forward dressing station behind the advanced lines and for fifteen hours treated the wounded and directed their evacuation while subjected to intense front and flank fire and in the absence of adequate shelter. His fearlessness under these conditions saved the lives of many wounded who would otherwise have been lost to the service. He disregarded personal danger and remained in an exposed position in order to give immediate care to the unfortunate."

COMMISSIONS OFFERED AND ORDERS TO DUTY ON ACCEPTANCE

Alabama

To Fort Oglethorpe for instruction, Lieuts. V. J. CRAGG, Clanton; T. DUNCAN, Sellers.

To Fort Sam Houston, Texas, Lieut. W. W. ROWAN, Alabama City.

Arizona

To Fort Riley for instruction, Lieuts. A. KIRMSE, Globe; G. E. GOODRICH, Phoenix.

To report to the commanding general, Western Department, Lieut. J. G. WILSON, Willcox.

Arkansas

To Camp Travis, Texas, Lieut. R. H. WILLETT, Jonesboro.

To Fort Oglethorpe for instruction, Lieut. S. HARRIS, Wilmar.

To Fort Riley for instruction, Capt. L. L. PURIFOY, Eldorado; Lieuts. T. HENDERSON, Argenta; P. A. RIDDLER, Fort Smith; C. R. CHESNUTT, Little Rock; E. W. BLACKBURN, Ozark; W. H. MOCK, Prairie Grove.

To Fort Worth, Texas, base hospital, for instruction, Capt. E. F. DAY, Arkansas City.

To Hoboken, N. J., Capt. J. N. CLIATT, Millwood.

To report to the commanding general, Southeastern Department, Lieut. T. E. JEFFERY, Fort Smith.

California

To Camp Cody, N. M., base hospital, for instruction, Capt. W. H. SMITH, Lieut. C. E. EARLY, Los Angeles.

To Camp Fremont, Calif., Capt. D. P. FLAGG, Los Angeles. Base hospital, Capt. C. L. LOWMAN, Los Angeles. Base hospital, for instruction, Capts. A. B. McCONNELL, Fresno; L. P. ADAMS, Oakland.

To Camp Kearney, Calif., Capt. J. H. TURNER, Huntington Park; Lieut. D. N. RICHARDS, Berkeley. Base hospital, Capt. C. P. PROUDFOOT, San Louis Obispo. Base hospital, for instruction, Capts. A. C. THORPE, Los Angeles; J. C. ROBERTSON, Modesto; C. G. HILLIARD, Redlands.

To Camp Lewis, Wash., Capts. J. E. HILL, Azusa; L. C. GREGORY, Fort Bragg; Lieuts. N. A. LEAKE, Gardena; T. H. TRINWORTH, Los Angeles. Base hospital, Capt. R. W. HARTWELL, Santa Barbara.

To Fort Oglethorpe for instruction, Capts. R. C. DUNDAS, J. A. GARLAND, Los Angeles; H. R. PAINTON, Lieut. J. N. TAVLOPOULOS, San Francisco.

To Fort Riley for instruction, Lieuts. J. A. DOUGHERTY, K. C. GUMMESS, San Francisco; F. H. KOEPKE, Watsonville.

To Fort Sam Houston, Texas, Capt. O. F. KONANTZ, Los Angeles.

To San Francisco, Calif., Letterman General Hospital, Lieut. J. SCHWARZ, San Francisco.

Colorado

To Camp Pike, Ark., base hospital, Capt. W. J. CHURCHILL, Longmont.

To Dallas, Texas, Love Field, Lieut. W. G. MUDD, Denver.

To Denver, Colo., Capt. J. H. ALLEN, Lieut. R. LEWIS, Denver.

To Fort Riley for instruction, Lieuts. K. F. ROEHRIG, L. H. RUEGNITZ, Denver.

To report to the commanding general, Southern Department, Lieut. W. W. YATES, Loveland.

Connecticut

To Camp Joseph E. Johnston, Fla., Lieut. T. E. PARKER, Waterbury.

To Fort Oglethorpe for instruction, Lieut. J. W. FRUIN, Waterbury.

To Hoboken, N. J., Lieuts. C. V. CALVIN, Bridgeport; L. F. HERZ, New Haven.

To New Haven, Conn., Yale Army Laboratory School, Capt. L. F. COCHEU, Hampton.

To Plattsburg Barracks, N. Y., Capt. L. A. NOTKINS, New Haven.

District of Columbia

To Camp Greene, N. C., base hospital, Lieut. E. A. TAYLOR, Washington.

Florida

To Camp Joseph E. Johnston, Fla., Capt. J. L. WEEKS, Perry; Lieut. S. E. DRISKELL, Raiford.

To Fort Oglethorpe for instruction, Capt. B. J. BOND, Tallahassee.

Georgia

To Camp Gordon, Ga., base hospital, Major F. P. CALHOUN, Atlanta.

To Camp McClellan, Ala., Lieut. W. A. NORTON, Savannah.

To Camp Wadsworth, S. C., Lieut. S. W. JOHNS, Doles.

To Camp Wheeler, Ga., Lieut. J. W. ODEN, Milledgeville.

To Fort Oglethorpe for instruction, Capts. L. C. ROUGHLIN, J. D. THOMSON; Lieuts. F. C. BIVINGS, Atlanta; B. S. BRANHAM, Sandersville; J. O. BALDWIN, Fort Gaines; J. F. SIGAFOOS, Honey Creek.

Hawaii

To report to the commanding general, Hawaiian Department, Capt. I. J. SHEPHERD, Honolulu.

To San Francisco, Calif., Letterman General Hospital, for instruction, Capt. H. H. BLODGETT, *Honolulu.*

Idaho

To Fort Riley, base hospital, for instruction, Lieut. D. E. CORNWALL, St. Maries. For instruction, Capts. J. FREMSTAD, Burley; J. D. SHINNICK, Cottonwood; C. B. ALLEN, Parma; Lieuts. E. L. HARGIS, Ashton; H. H. DUTTON, Hailey; E. E. HARDY, Kellogg; J. N. DAVIS, Kimberly; E. H. ELMORE, Rupert.

Illinois

To Camp Custer, Mich., Lieut. J. M. DURIN, Chicago. Base hospital, Capts. H. P. BAGLEY, E. P. NORCROSS, Chicago.

To Camp Grant, Ill., Capts. L. H. FRIEDRICH, C. B. KING, U. G. WINDELL; Lieut. J. E. KOONS, Chicago. *To examine the command* for nervous and mental diseases, Lieut. T. G. McLIN, Jacksonville.

To Camp McClellan, Ala., Lieut. A. J. PROMINSKI, Chicago.

To Camp Shelby, Miss., base hospital, for instruction, Capt. F. G. MORRILL, Havana.

To Camp Sherman, Ohio, base hospital, for instruction, Capts. R. S. BARNSBACK, Edwardsville; W. R. PARKES, Evanston.

To Camp Zachary Taylor, Ky., Lieut. H. A. LONG, Effingham.

To Fort Benjamin Harrison, Ind., Lieut. C. R. BATES, Roodhouse.

To Fort Oglethorpe for instruction, Capts. G. A. ALMFELT, C. E. BODDIGER, Chicago; F. P. HORAN, Evanston; L. A. BURHANS, Peoria; Lieuts. A. J. KLINT, C. W. LENHART, Danville; W. F. BOWMAN, Fishhook; R. G. DAKIN, Sandwich.

To Fort Riley for instruction, Capts. W. A. UEHREN, Aurora; W. T. ZIEGLER, Canton; A. PECH, Chicago; W. N. MacCHESNEY, Chicago Heights; O. P. GRANT, Easton; W. A. GOTT, Washington; Lieuts. O. F. REINHARDT, Aviston; E. A. BEHRENDT, Bloomington; W. R. ABBOTT, G. L. APFELBACH, M. L. ARKIN, N. L. BLITZSTEN, E. J. COHN, C. C. COOLEY, C. F. GOETZINGER, L. CROTOWSKI, F. C. KLOOS, C. A. KROGH, T. F. LEATHERWOOD, J. G. WIEDDER, J. B. WILCOX, E. F. WINTERBERGER, Chicago; O. J. CULBERTSON, East St. Louis; C. S. WILLIAMSON, Fairmount; R. M. HATHAWAY, Farmer City; C. H. FOOTE, Girard; C. L. VANATTA, Hidalgo; A. C. MOORHEAD, Leland; W. M. CATON, Mason City; B. H. HARDINGER, Mattoon; F. E. INKS, Polo; M. A. NIX, Princeton; C. V. WINSETT, Prophetstown; J. C. MURPHY, Ridgeway; A. J. DALTON, St. Joseph.

To Roland Park, Md., Lieut. W. T. MORFETT, Blue Mound.

Indiana

To Ann Arbor, Mich., State Psychopathic Hospital, for intensive training, Capt. H. B. SHACKLETT, New Albany.

To Camp Meade, Md., Lieut. G. R. HAYS, Richmond.

To Camp Sevier, S. C., Lieut. J. P. WOLF, New Market. Base hospital, Capt. J. R. SICKLER, Frankfort.

To Camp Zachary Taylor, Ky., base hospital, Capt. C. E. DUFFIN, Richmond. Base hospital, for instruction, Capt. C. E. VARIER, South Bend.

To Colonia, N. J., Capt. W. C. WINSTANDLEY New Albany.

To Denver, Colo., Capt. B. ERDMAN, Indianapolis.

To Fort Benjamin Harrison, Ind., Lieuts. J. C. KINCAID, Indianapolis; J. A. MEINER, Kokomo.

To Fort Oglethorpe for instruction, Capts. J. W. LITTLE, C. W. MARXER, Indianapolis; C. E. GILLESPIE, Seymour; O. S. TAYLOR, Whitestown; Lieuts. G. ALEXANDER, Bedford; I. J. GILL, Dugger; E. B. FLAVIEN, Logansport.

To Fort Riley, Capt. F. RODENBECK, Arcadia. For instruction, Capts. W. G. CULLODEN, F. P. REID, Indianapolis; J. D. STURDEVANT, Noblesville; Lieuts. C. M. [illegible]; W. A. HODGES, Emison; I. T. OLIPHANT, Farmersburg; [illegible] D. SKEEN, Gary; C. R. PRICE, Geneva; C. U. THRALLS, Hymera; H. S. LEONARD, A. L. WALTERS, Indianapolis; C. M. WRAY, New Richmond; V. A. SHANKLIN, West Terre Haute.

Iowa

To Camp Dodge, Iowa, Lieuts. N. S. BEVINS, Fort Atkinson; F. E. E. ST. CLAIR, Hampton. Base hospital, for instruction, Lieut. G. B. BROWN, Clairion.

To Camp Grant, Ill., Capt. J. H. SCHRUP, Dubuque. Base hospital, for instruction, Lieut. P. M. DAY, Jr., Barnes City.

To Fort Oglethorpe for instruction. Capts. E. RICE, Ames; I. W. TRAVERSE, Fort Mediann; B. COURSHON, Sioux City; Lieuts. R. R. HARRIS, Dubuque; R. E. BRISBINE, Mason City; H. M. HUSTON, Ruthven; F. L. NICHOLS, Sutherland.

To Fort Riley for instruction, Capt. O. KREJSA, Cedar Rapids; Lieuts. S. M. FERGUSON, Avoca; C. E. LOWREY, Centerville; B. F. McNEILL, Charles City; L. W. WARD, Fairbank; A. A. ROSE, Gilbert; A. J. MEYER, Hawarden; A. F. WATTS, Iowa City; J. J. PITCHER, Mt. Pleasant; V. O. MUENCH, Nichols; I. A. SNYDER, Roland; C. C. COLLESTER, Spencer; F. S. BOWEN, Woodburn.

Kansas

To Camp Grant, Ill., Lieut. R. M. TROUP, Garden City.

To Fort Oglethorpe for instruction, Capts. J. G. KENNEDY, Altoona; J. L. GROVE, Newton; Lieut. E. L. KALBFLEISCH, Newton.

To Fort Riley for instruction, Capts. B. R. RIEY, Benedict; H. A. BROWNE, Galena; F. K. MEADE, Hays; Lieuts. L. M. HINSHAW, Bennington; C. R. McFARLAND, Blue Rapids; A. JOHNSON, Clyde; R. P. PIERCE, Dunkirk; W. R. MORTON, Green; C. N. JOHNSON, Wichita.

Kentucky

To Ann Arbor, Mich., State Psychopathic Hospital, for training, Lieut. W. E. RENDER, Lakeland.

To Camp Greene, N. C., Lieuts. S. M. LINVILLE, Centerville; O. D. BROCK, London; J. S. WHITSON, Slaughters; D. J. THOMPSON, Webbville.

To Camp Jackson, S. C., base hospital, for instruction, Capt. J. A. DAVIS, Covington.

To Camp Joseph E. Johnston, Fla., Capt. J. M. FERGUSON, Central City; Lieut. C. L. NICHOLS, Louisville.

To Camp Meade, Md., Lieut. M. COMBS, Pineville.

To Camp Sevier, S. C., Lieut. B. C. OVERBOY, La Center.

To Fort Benjamin Harrison, Capts. W. T. BARNETTE, Springfield; B. J. NEARY, Waverly.

To Fort Oglethorpe for instruction, Capts. J. M. SALMON, Ashland; J. D. JACKSON, V. RAWSON, Danville; C. H. STRUBLE, Dayton; C. A. VANCE, Lexington; G. S. BROCK, London; D. A. PENICK, Nicholasville; E. B. SMITH, Shelbyville; W. A. BUSH, Winchester; Lieuts. H. S. HARNED, Boston; E. L. GOWDY, Campbellsville; J. N. SMITH, Christianburg; A. G. CALDWELL, Covington; A. P. DOWDEN, Eminence; S. W. COHN, Fulton; C. R. MORTON, Hanson; A. E. POPHAM, Knottsville; H. F. POHLMEYER, Lexington; C. W. KASH, Foorefield; P. K. McKENNA, Mount Sterling; A. R. KEMPF, Olmstead; H. V. USHER, Oscar; M. H. WALKER, Panther; O. P. CHAPMAN, Port Royal; D. G. SKAGGS, Prospect; E. BARR, Rome; H. B. ANDERSON, Shawhan; W. L. MORSE, St. Charles.

To Fort Riley for instruction, Lieuts. J. N. BAILEY, Fredonia; J. W. FITCH, Louisville.

To Newport News, Va., Lieut. E. E. LINVILLE, Mount Olivet.

Louisiana

To Camp Beauregard, La., Lieut. J. F. POLK, Slidell. Base hospital, Lieut. E. McCARTHY, New Orleans.

To Camp Joseph E. Johnston, Fla., Lieuts. J. W. A. SMITH, New Orleans; T. BUTLER, St. Francisville.

To Fort Oglethorpe for instruction, Lieuts. A. B. CHILDS, Eunice; J. G. HIRSCH, Harvey; C. A. BEATLE, J. B. HARNEY, H. B. SEEBOLD, New Orleans; M. S. PICARD, Shreveport; A. M. PETERS, Winnfield.

To New York, Neurological Institute, for instruction, Lieut. J. I. PETERS, Alexandria.

Maine

To Newport News, Va., Capt. E. CAPLAN, Portland.

Maryland

To Camp Jackson, S. C., base hospital, for instruction, Lieut. W. N. PALMER, Easton.

To Camp Meade, Md., base hospital, Capt. H. K. FLECKENSTEIN, Baltimore.

To Fort Oglethorpe for instruction, Lieuts. I. C. DICKSON, E. C. LEHNERT, Baltimore; J. H. BAY, Harve de Grace; F. A. MILLER, Salisbury.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. H. FRIED, Baltimore.

To Newport News, Va., Capt. B. S. HANNA; Lieuts. A. G. WEBSTER, Baltimore; W. H. COULBOURN, Crisfield; F. T. BROOKS, Federalsburg.

Massachusetts

To Camp Abraham Eustis, Va., Lieut. W. W. MARSTON, Newton.

To Camp Devens, Mass., base hospital, Major F. H. VERHOEFF, Boston. Base hospital, for instruction, Capt. J. P. GRAHAM, Springfield; Lieut. A. E. DARLING, Lynn.

To Camp Dix, N. J., base hospital, for instruction, Lieut. G. J. CONNOR, Haverhill.

To Camp Meade, Md., Lieut. H. M. KEMP, Greenfield.

To Fort Oglethorpe for instruction, Capts. F. E. DRAPER, J. S. MAY, Boston; T. F. BRASSIL, Cambridge; R. A. RICE, Fitchburg; W. L. HALE, North Attleboro; A. L. BROWN, Winchester; Lieuts. C. E. MEYER, Chicopee; P. J. SULLIVAN, Dalton; G. A. CONNOR, East Cambridge; F. F. DEXTER, Longmeadow; E. L. HILL, Millis; A. O. METIVIER, [illegible] CONNELL, Walpole; R. M. MARR, Westfield; M[illegible]

To Hoboken, N. J., Lieuts. L. LAKE, Cambridge; R. N. BROWN, Malden.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. F. D. JONES, Springfield.

To Newport News, Va., Lieut. M. M. MURPHY, Brockton.

Michigan

To Camp Custer, Mich., base hospital, for instruction, Lieuts. B. S. LONEY, Detroit; E. S. THORNTON, Muskegon.

To Camp Zackary Taylor, Ky., Lieuts. G. SEWELL, Detroit; J. J. O'MEARA, Jackson.

To Fort Benjamin Harrison, Lieut. L. E. WESTCOTT, Cobleville.

To Fort Oglethorpe for instruction, Capt. G. A. SEYBOLD, Jackson; Lieut. H. L. MECK, Petersburg.

To Fort Riley for instruction, Lieuts. L. E. WERRY, Calumet; F. C. MUSSER, C. M. TURRELL, Detroit; E. T. BRUNSON, Ganges.

To Washington, D. C., Lieut. C. W. HEALD, Battle Creek.

Minnesota

To Camp Dodge, Iowa, base hospital, Capt. G. E. BENSON, Minneapolis. Base hospital, for instruction, Capt. A. N. COLLINS, Duluth.

To Camp Grant, Ill., base hospital, for instruction, Lieut. C. LEMBKE, St. Paul.

To Camp Lee, Va., base hospital, Capt. P. A. HIGBEE, Minneapolis.

To Fort Riley for instruction, Lieuts. C. F. CARSTENS, Hibbing; D. M. O'DONNELL, Ortonville; B. W. JARVIS, St. Paul.

To Newport News, Va., Capt. J. L. CRENSHAW, Rochester.

Mississippi

To Camp Beauregard, La., Lieut. J. M. Smith, Magnolia.

To Camp Joseph E. Johnston, Fla., Capts. H. L. McKINNON, Hattiesburg; W. D. McCALIP, Yazoo City; Lieuts. O. H. OLSEN, Hattiesburg; B. C. CRISLER, Itta Bena; B. F. McARTHUR, Lizelia; D. T. BROOK, McComb; H. B. OLIVER, Sledge.

To Camp McClellan, Ala., Lieut. J. C. BUCK[illegible]ville.

To Fort Oglethorpe for instruction, Capt. M. [illegible] Lieuts. R. E. HONNOLL, Ashland; D. W. MAGEE, [illegible] PEARCE, Falkner; O. O. AUSTIN, Harperville.

To Fort Riley for instruction, Lieut. L. H. BREVARD, Eudora.

Missouri

To Camp Beauregard, La., base hospital, for instruction, Lieut. E. BOEHM, St. Louis.

To Camp Dodge, Iowa, base hospital, Capt. S. L. GETTYS, St. Louis.

To Camp Grant, Ill., base hospital, Lieut. C. D. SCOTT, St. Louis.

To Camp Logan, Texas, base hospital, Lieut. H. G. PIEPER, St. Louis.

To Camp Pike, Ark., base hospital, Capt. O. A. SMITH, Farmington.

To Camp Zachary Taylor, Ky., base hospital, for instruction, Capt. W. H. GENTRY, Carthage.

To Fort Oglethorpe for instruction, Capt. J. H. FULBRIGHT, Springfield; Lieuts. U. G. STREIBY, Brownington; J. W. L. BRENNAN, St. Louis; J. L. HORN, Williamsville.

To Fort Riley for instruction, Capts. T. P. FORE, Brookfield; W. J. CLARK, Maysville; E. W. SHRADER, Moberly; A. L. McNAY, Pacific; B. B. SIMMONS, St. Joseph; C. E. DUDLEY, E. LOEW, J. A. LOTZ, C. H. POPE, St. Louis; Lieuts. G. H. SHIRLEY, Argyle; J. BEST, High Hill; J. A. BEEBE, H. CZARLINSKY, C. F. MARTIN, Kansas City; J. F. GULIC, Koshkonong; H. W. OYLER, Mill Grove; E. E. EVANS, New Florence; C. H. CULLERS, Spickard; R. L. BYRD, H. B. DePEW, J. E. DOLL, M. J. GLASER, C. F. HENKE, C. R. REIDER, P. H. SCHERER, F. J. SMITH, W. F. STEIN, O. VIERLING, St. Louis; A. TRAUBITZ, Vanduser; A. J. COURSON, Williamsburg.

Montana

To Camp Dodge, Iowa, base hospital, for instruction, Capt. W. V. KINGSBURY, Butte.

To Camp Grant, Ill., base hospital, for instruction, Capt. J. G. THOMPSON, Helena.

To Fort Riley for instruction, Lieuts. R. B. DURNIN, F. E. KEENAN, Great Falls.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. J. C. F. SIEGFREIDT, Bearcreek.

Nebraska

To Camp Bowie, Texas, base hospital, for instruction, Lieut. C. C. HICKMAN, Lincoln.

To Camp Dodge, Iowa, base hospital, for instruction, Lieut. R. L. IVINS, Crawford.

To Camp Gordon, Ga., base hospital, Capt. I. S. CUTTER, Omaha.

To Fort Oglethorpe for instruction, Lieuts. T. T. HARRIS, B. A. McDERMOTT, Omaha.

To Fort Riley for instruction, Capt. F. J. KALAL, Clarkson; Lieuts. G. W. BRIGGS, Arthur; C. E. KIDDER, Holstein.

New Hampshire

To Fort Oglethorpe for instruction, Lieuts. L. B. MARCOU, Berlin; F. H. LOVEJOY, Milford.

To report to the commanding general, Southeastern Department, Capt. J. E. BLAKE, Lisbon.

New Jersey

To Bound Brook, N. J., Lieut. J. T. LEAHY, Bound Brook.

To Camp A. A. Humphreys, Va., Capts. H. D. McCORMICK, Kenvil; F. A. ROBERTS, Newark.

To Camp Colt, Pa., Lieut. G. H. LEBRET, Secaucus.

To Camp Crane, Pa., Lieuts. G. R. WRIGHT, Landing; H. H. RICH, Newark.

To Camp Devens, Mass., base hospital, Capt. E. A. CURTIS, Newark.

To Camp Dix, N. J., base hospital, Capt. S. W. CLARK, Atlantic City; Lieut. J. F. BOWMAN, Irvington.

To Camp Jackson, base hospital, for instruction, Lieut. W. SPICKERS, Paterson.

To Camp Lee, Va., to examine the command for nervous and mental diseases, Lieut. G. B. McMURRAY, Greystone Park.

To Camp McClellan, Ala., base hospital, Lieut H. G. HOLLER, Newark.

To Camp Meade, Md., Lieut. A. W. BOWKER, Atlantic City.

To Camp Sevier, S. C., to examine the command for nervous and mental diseases, Lieut. G. W. DAVIES, Cedargrove.

To Camp Wadsworth, S. C., to examine the command for nervous and mental diseases, Lieut. G. R. HAMPTON, Greystone Park.

To Fort Oglethorpe for instruction, Capts. W. H. AXFORD, Bayonne; T. P. BOYLE, Newark; H. D. WEBB, Orange; Lieuts. M. S. FRANK, C. J. LARKEY, Bayonne; H. C. UPCHURCH, Dover; A. V. SIMMONS, Irvington; E. L. CREVELING, N. L. ROWE, JR., Jersey City; R. M. COHN, L. R. DAVIS, Newark; H. C. CASSINI, Orange; H. B. HESS, C. J. KANE, Paterson; W. COTTRELL, Rutherford; I. M. DANE, South Orange; W. S. McDANNALD, Tenafly; A. UREVITZ, West Hoboken; W. FESSLER, West New York.

To Hoboken, N. J., Capt. W. GAUCH, Newark; Lieuts. J. J. HUNT, Bayonne; J. P. COLL, Newark; J. G. COTTRELL, Perth Amboy.

To Lakewood, N. J., Capt. T. ALSOP, Atlantic City.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. H. A. SCHEPPACH, Newark.

To Newport News, Va., Lieut. H. J. GILBERT, Newark.

To Washington, D. C., St. Elizabeth's Hospital, for intensive training, Lieut. N. W. LAWLESS, Morristown.

New Mexico

To Fort Riley for instruction, Lieut W. M. LANCASTER, Plain.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to Camp Grant, Ill.*, base hospital, for instruction, from Fort Riley, Capt. C. L. FAHNESTOCK, McCook.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Greene, N. C.*, from Fort Oglethorpe, Capt. W. T. CARSON, Hastings.

Nevada

To Camp Crane, Pa., evacuation hospital, from Camp Kearney, Capt. E. K. SMITH, Lovelock.

New Hampshire

To Camp Devens, Mass., from Fort Oglethorpe, Lieut. G. A. TREDICK, Portsmouth.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Devens, Mass.*, base hospital, for instruction, from Fort Oglethorpe, Lieut. E. H. THOMPSON, Hampton.

To Walter Reed General Hospital, D. C., from Fort Oglethorpe, Lieut. F. B. CLOW, Wolfeboro.

New Jersey

To Camp Abraham Eustis, Va., to examine the command for nervous and mental diseases, from Washington, Lieut. E. H. SNAVELY, Cedar Grove.

To Camp Greene, N. C., base hospital, from Camp Jackson, Major C. E. SUTPHEN, Newark; from Fort Oglethorpe, Lieut. M. E. STREEN, Newark.

To Camp Hancock, Ga., base hospital, from Fort Oglethorpe, Capt. C. R. NEARE, East Orange; Lieut. R. D. VREELAND, Passaic.

To Fort Oglethorpe, base hospital, from Camp Jackson, Lieut. I. S. INGBER, Secaucus.

New York

To Army Medical School for instruction, from Hoboken, Lieut. T. M. CALLADINE, Perry.

To Camp Cody, N. M., for instruction, from Fort Slocum, Major R. E. PARRISH.

To Camp Crane, Pa., base hospital, from Camp Lewis, Capt. R. M. JONES, New York. Mobile hospital, from Fort Oglethorpe, Lieut. A. B. BRUNER, R. V. FUNSTEN, New York.

To Camp Devens, Mass., base hospital, for instruction, Lieut. H. HARRIS, New York.

To Camp Hancock, Ga., base hospital, from Camp Jackson, Capt. J. H. EVANS, Virgil; from Fort Oglethorpe, Lieuts. C. A. LEE, Brooklyn; E. W. PRESLEY, Staten Island. Base hospital, for instruction, Lieut. N. H. GOLDBERG, New York.

To Camp Jackson, S. C., base hospital, Lieut. M. GLEICH, New York.

To Camp Lee, Va., base hospital, Lieut. J. RYBACK, Brooklyn.

To Camp Logan, Texas, from Fort Oglethorpe, Lieut. O. J. COOK, New York.

To Camp MacArthur, Texas, base hospital, for instruction, from Fort Oglethorpe, Lieut. I. E. SUMNER, Brooklyn.

To Camp McClellan, Ala., base hospital, for instruction, from Fort Oglethorpe, Lieut. E. W. WILKINS, Albany.

To Camp Meade, Md., from Syracuse, Capt. D. E. BRACE, New York. Base hospital, for instruction, Lieut. D. M. FULLER, New York. Evacuation hospital, from Camp Laurel, Lieut. D. G. DUDLEY, Endicott; from Fort Oglethorpe, Lieut. C. L. LARKIN, New York.

To Camp Wheeler, Ga., from Washington, Major H. R. GAYLORD, Buffalo.

To Camp Zachary Taylor, Ky., base hospital, from Camp Greene, Capt. J. R. SWANICK, Saratoga Springs.

To Chanute Field, Rantoul, Ill., as flight surgeon, from Hazelhurst Field, Capt. W. A. SCRUTON, New York.

To Fort Benjamin Harrison, from Southern Department, Capt. A. C. CALISCH, Oswego.

To Fort Oglethorpe, from Knoxville, Tenn., Lieut. L. JACOBS, Brooklyn. Base hospital, from Camp Wheeler, Lieut. R. G. BLOOD, New York. For instruction, Lieuts. J. BECKENSTEIN, Brooklyn; I. GREENBERG, J. G. J. GRIMLEY, New York.

To Hoboken, N. J., from Fort Porter, Capt. A. J. CAPRON, Oswego; from Washington, Lieut. T. J. VOSBURGH, Warwick. Base hospital, from Camp McClellan, Lieut. S. S. ARLUCK, New York.

To Lakewood, N. J., Lieuts. L. T. MANN, New York.; P. J. WHITE, Jr., Staten Island; from New Haven, Capt. C. W. FIELD, New York.

To New York, Neurological Institute, for instruction, Lieut. J. RESNIK, New York.

To Otisville, N. J., from Fort McPherson, Capt. R. E. PLUNKETT, Whitehall.

To Pittsburgh, Pa., Lieut. A. VALENSI, New York.

To Rahway, N. J., from Boston, Lieut. H. F. MORRISON, Tuxedo Park.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to Camp Sherman, Ohio*, base hospital, for instruction, from Fort Riley, Lieut. F. A. SHARPE, New York.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Meade, Md.*, base hospital, for instruction, from Fort Oglethorpe, Lieut. J. L. KINNER, Elmira.

To Walter Reed General Hospital, D. C., from Fort Oglethorpe, Lieut. H. L. PRINCE, Rochester.

To Washington, D. C., from Camp MacArthur, Major J. T. SPRAGUE, Staten Island; from Walter Reed General Hospital, Lieut. H. P. SAWYER, Troy.

To West Point, N. Y., to give orthopedic instruction, and on completion *to Fort Hancock, N J.*, from Plattsburg Barracks, Major B. H. WHITBECK, New York.

To Williamsbridge, N. Y., from Camp Sheridan, Capt. S. W. ROOF, New York.

The following order has been revoked: *To Fort Oglethorpe* for instruction, Lieut. A. WINKELSTEIN, Syracuse.

North Carolina

To Camp Sherman, Ohio, from Fort Oglethorpe, Lieut. R. B. WILKINS, Raeford.

To Lakewood, N. J., Lieut. D. H. NISBET, Charlotte.

North Dakota

To Camp Lewis, Wash., for instruction, from Camp Dodge, Capt. A. M. FISHER, Bismark.

Ohio

To Austin, Texas, State University, from Fort Sill, Lieut. F. S. VAN DYKE, Columbus.

To Camp A. A. Humphreys, Va., from New Haven, Lieut. A. J. FOX, Cincinnati.

To Camp Abraham Eustis, Va., for instruction, from Columbus Barracks, Major L. J REGAN

To Camp Crane, Pa., mobile hospital, from Fort Oglethorpe, Capt. E. W. FISHER, Portage; Lieut. F. F. DAVIS, East Liverpool.

To Camp Custer, Mich., as camp surgeon, from Camp Pike, Lieut.-Col. E. F. McCAMPBELL, Columbus.

To Camp Greene, N. C., base hospital, from Camp Shelby, Lieut. C. V. DAVIS, Cleveland.

To Camp Hancock, Ga., base hospital, from Camp Bowie, Capt. H. M. OSBORNE, Youngstown; from Fort Oglethorpe, Lieut. T. HULICK, Cincinnati.

To Camp Jackson, S. C., base hospital, for instruction, from Fort Oglethorpe, Lieut. J. K. HAMILTON, Youngstown.

To Camp McClellan, Ala., base hospital, for instruction, Lieut. H. A. BAUGHN, Washington C. H.

To Camp Sherman, Ohio, from Army Medical School, Lieut. V. R. TURNER, Newark. Base hospital, from Fort Oglethorpe, Lieut. P. M. SPURNEY, Cleveland. Base hospital, for instruction, Lieut. O. G. GRADY, Orrville.

To Camp Zachary Taylor, Ky., base hospital, for instruction, Lieut. F. J. GALLAGHER, Cleveland.

To Fort Oglethorpe, base hospital, from Army Medical School, Major R. D. MADDOX, Cincinnati.

To Rahway, N. J., from Boston, Lieut. H. E. BUNDY, Milwaukee.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to Fort Des Moines, Iowa*, for instruction, from Fort Riley, Lieut. J. M. ROSS, Bloom City.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Surg. B. W. BROWN, directed to attend conventions of social service council of Canada at various places and also local city conventions in the State of Washington, to deliver addresses on venereal disease control.

Surg. L. P. H. BAHRENBERG, proceed to Jefferson City, Mo., for conference with state authorities on venereal disease control.

Surg. G. W. McCOY, proceed to Boston, Mass., and other places deemed advisable for laboratory studies relative to the etiology of influenza and other infectious diseases.

P. A. Surg. W. L. TREADWAY, proceed to Trenton, N. J., and assume charge in connection with state and local authorities of the control of the influenza epidemic.

Asst. Surg. P. M. STEWART, *proceed to Boston*, Mass., to duty in connection with the control of the spread of influenza.

Asst. Surg. R. R. SAYERS, proceed to Boston, Mass., for duty *in* connection with the control *of the spread* of influenza.

Asst. Surg. R. L. DeSAUSSURE, proceed to Boston, Mass., for duty in connection with the *control* of the spread of influenza.

Asst. Surg. H. S. MUSTARD, assume charge of service operations in the District of *Columbia* in order to properly safeguard the health of the military forces and the government *employees*.

Asst. Surg. C. E. GIBBS, proceed *to* Washington, *D*. C., for duty in measures for the control of influenza.

Pharmacist F. J. HERTY, proceed to Boston, Mass., for duty *in* connection with *the control* of the *epidemic* of influenza.

A. A. Surg. PERCY AHRONS, relieved *at Atlanta*, Ga., proceed to Raleigh, N. C., for duty in extra-*cantonment sanitation*.

A. A. Surg. EDWARD B. HELFRICH, proceed to Newport News, Va., for duty in extracantonment *sanitation*.

A. A. Surg. J. M. BIED[illegible] Va., and assume charge of the sanitary wor[illegible] plant.

A. A. Surg. EUGENE [illegible]vport News, Va., for duty in extracantonment sanitation.

A. A. Surg. JAMES W. RICHARDS, proceed to Wilmington, Del., for duty in venereal disease control *measures*.

A. A. *Surg*. B. F. *ROBERTS*, relieved at Newport News, Va., *pro*ceed to Washington, D. C., for *duty in* measures for the control *of influenza*.

A. A. Surg. A. L. SMEDLEY, proceed *to* Alexandria, Va., for duty *in* extracantonment sanitation.

Asst. Educational Director DAVID ROBINSON, proceed to necessary points in the states of New York, Ohio, *Illinois*, Minnesota, *Iowa*, Nebraska, Wyoming, and Colorado for conference relative *to* the instructions to drafted *men* to be carried out under service *super*vision.

Scientific Asst. W. H. PRICE, *relieved* at Anniston, Ala., proceed *to* Augusta, Ga., to assume charge of service operations.

Scientific Asst. SAMUEL SAUNDERS, relieved at Brunswick, Ga., proceed to Washington, D. C., for duty in measures *for the* control of influenza.

Asst. Epidemiologist C. C. APPLEWHITE, relieved at Englewood, N. J., proceed to Atlanta, Ga., and assume charge of service operations.

Asst. San. Engineer J. G. FOSTER, relieved at Gulfport, Miss., proceed to Fayetteville, N. C., for duty in extracantonment sanitation.

San. Inspector HARRY S. LUCAS, proceed to Washington, D. C., for duty in measures for the control of influenza.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Tribute to Former Surgeon-General Gorgas and Major-General Noble.—In a discussion in the House of Representatives, Oct. 2, 1918, on a bill to provide an additional building for the United States Public Health Service, Representative Bankhead paid the following tribute to Surgeon-General Gorgas:

> And, in this connection, Mr. Chairman, it just occurred to me that in a very few weeks, on account of reaching the age limit, the great Surgeon-General of the United States, Gen. William C. Gorgas, will be retired from his present position. I want to say that the people of my native State of Alabama took a great pride in the achievements of that great medical man. His usefulness not only reflects itself in the gratitude of the people of Alabama, but the people of the United States and of foreign countries are under everlasting obligations to that man, whose genius and skill have accomplished so much in the conservation of human life.
>
> As was suggested a few moments ago, he made it possible by the sanitation that he perfected in the Panama Canal Zone to make that great interoceanic canal a reality, and inasmuch as it is largely conceded it was a dream of that great old Alabaman, Senator John T. Morgan, to construct that canal, in just as large measure General Gorgas played a part in the fruition of that enterprise. I feel sure that the Government itself, that the Members of Congress and those who are familiar with his service, will regret the retirement from his present official position of Gen. William C. Gorgas, Surgeon-General.

Following this statement Representative Burnett of Alabama paid the following tribute to General Noble:

> In addition to what my colleague from Alabama has said about General Gorgas, I desire to call the attention of the committee to the fact that there is another great Alabaman that stands perhaps second to him in rank and ability in the Surgeon-General's Office, and that is General Noble, of Anniston, Ala., who was with General Gorgas all through his wonderful career in Panama. Alabamans had hoped that when General Gorgas retired, General Noble would be promoted to the position of Surgeon-General. The press carries a report, however, that perhaps another great surgeon, who is now in France, will probably be transferred to this great work on this side, and that General Noble will be assigned to the duties now being performed by that other great surgeon, General Ireland.
>
> I desire to say that those of us who know General Noble believe that there can be no more efficient man assigned to either one of the duties. I know him; I know his family; I know his ancestry, and I believe that to whatever field of operation he may be assigned he will perform the work with the same efficiency that has accompanied every work that he has been assigned to by the Government since he has been in its service.

ARKANSAS

Influenza.—October 8, a statewide quarantine was declared against places where influenza had occurred, and all places of public assemblage were closed. Public travel was not prohibited. According to the report of Dr. J. C. Geiger, representative of the Public Health Service in the state, there had been 1,800 cases of influenza in Little Rock and vicinity, of which 65 per cent. had recovered. Thirty per cent. of the new cases were in children. The pneumonia cases were 1.7 per cent. of the total number of cases and the deaths resulting from complications amounted to 0.2 per cent. An isolation hospital was opened in Little Rock, October 9; the city was divided into districts and a nursing service provided by the Public Health Service.

CALIFORNIA

Health Center.—A health center for the examination of children under 6 years of age was opened at Santa Rosa, October 5. The center will be open daily between 10 and 12 a. m. Dr. Elizabeth M. Yates was in charge on the opening day. All children of less than 6 years will be examined free, and advice will be given as to diet, etc. It is hoped that all babies examined during Better Baby Week will be brought for reexamination so that improvement may be noted, and further advice given if necessary.

ILLINOIS

Physical Defects Removed.—Major John M. Dodson, Chicago, medical aide to Governor Lowden has perfected a plan whereby selective draft men in Class B, which is the remediable group will be able to secure treatment before being inducted into service.

Museum as War Hospital.—It is announced that the new Field Columbian Museum, Grant Park, Chicago, has been offered to the government as a war hospital, and that the offer has been accepted. The building is to be remodeled so as to accommodate 4,300 sick and wounded soldiers, and the construction of a number of buildings for the use of nurses is to be begun at once. The building is on a site 6 acres in extent.

Illegal Practitioners Fined.—G. B. Black, Norris City, White County, was arrested by the Department of Registration and Education of the State of Illinois and fined $450 for practicing medicine without a license. The fine and costs in the case amounted to $725. Black has been practicing medicine in White County for twenty years and has openly defied the authorities to prosecute him. Thomas Deschauer, 702 East Sixty-Third Street, Chicago, was also arrested by the department for practicing medicine without a license and was fined $50 and costs by the court. The department caused the arrest of Mrs. J. McPhee of Joliet, who was found practicing medicine without a license. She was fined $100 and costs.

Tuberculosis at Camp Grant.—The examination of men who have had influenza for possible tuberculous infection is now engaging the attention of Major Clarence L. Wheaton and his corps of assistants who have the matter of camp tuberculosis in their charge. Up to the beginning of the epidemic of influenza, measles had been the special matter of interest to those engaged in the tuberculosis department. Through the efforts of this department tuberculosis in the camp has been kept as low as 1 per cent., and sometimes not a case was on hand. Since the clearing house for examinations of suspects of this sort was established 800 men have been examined. Those suspected of being tuberculous have been placed in the tuberculosis ward of the base hospital for observation and treatment and until final disposition of their cases, which means that they are either returned to their homes or are sent to some government sanatorium for further treatment.

Chicago

Personal.—Dr. H. I. Davis, Chicago, left Wednesday for New York to sail at once for France for service with the American Red Cross.——Dr. James J. McGuinn, Chicago, has been appointed assistant commander of the medical zone in charge of the reconstruction of wounded soldiers in France, by the American Red Cross and has started for his new post of duty.

MARYLAND

Medical Library Closed.—It has been decided that the library of the Medical and Chirurgical Faculty of Maryland will close at 6 p. m. excepting on Fridays. This change is in order to save light and service.

Sanitary Work in Military Zones.—The state department of health has asked the Maryland Council of Defense for an appropriation of $15,000 to continue the sanitary work in military zones in Maryland. Zones have already been established at Fort Howard, Holabird, Edgewood, Aberdeen, Indian Head, and Solomons Island, Curtis Bay, Ordinance Depot, and the Camp Meade area. To supervise these zones ten inspectors will be needed in addition to the number furnished by the board of health. The department has also asked for an appropriation of $6,000 for the control of venereal disease in the state.

Personal.—Lieut.-Col. William H. Welch, Baltimore, attached to the Surgeon-General's staff at Washington, D. C., is recovering from an attack of influenza.——Lieut.-Col. Thomas R. Boggs, Baltimore, has been made chief medical consultant for the air service of the American Expeditionary Forces, attached to general headquarters.——Lieut. Walter L. Denny of Baltimore, who has been ill at Fort Oglethorpe with influenza, is reported improving.——Dr. Benjamin F. Grove, Baltimore, 60 years old, is at St. Joseph's Hospital suffering from contusions of the head and probably a fractured skull as the result of a fall.

MINNESOTA

Regulations Regarding Burial of Influenza Victims.—The state board of health has made an announcement in regard to handling the bodies and burial of victims of influenza. In the case of deaths occurring in the state, public funerals will not be permitted. In the case of bodies of soldiers returned to Minnesota, public funerals will be permitted on condition that the casket be not opened, and that any escort returning with the body may not attend such funerals or mingle with the public.

Report on Venereal Diseases.—The report of the Division on Venereal Diseases of the Minnesota State Board of Health shows that during the quarter ending September 30 the average monthly expenditure per month was about $2,700 in the administration of the venereal disease regulations. A regulation by the state board prohibiting the sale of venereal disease remedies by pharmacists was endorsed in about fifty replies to a circular letter addressed to them. There have been some violations of the regulation, and a number of druggists will be cited before the state board before prosecution in the courts. An inventory of venereal disease remedies in the stores is being taken. Clinics have been organized, one for women in Minneapolis run by the City Health Department, and a men's clinic at the university for two evenings a week which is being partially financed by the state board. An evening dispensary for men and women was arranged for in St. Paul, and a clinic for both sexes was opened, October 1, in Duluth. During the quarter there were distributed to various departments, dispensaries and institutions, 408 doses of arsenobenzol, 152 Wassermann tests were made and fifty-seven examinations for gonorrhea. Much educational work was done and literature was distributed. A system of reporting cases was inaugurated, August 1, and during that month 620 cases were reported by 137 physicians, of which there were 356 of syphilis, 249 of gonorrhea and fifteen of chancroid. In September, 438 cases were reported, 225 of syphilis, 199 of gonorrhea and fourteen of chancroid. Forty-four physicians were added to the list of those reporting. Through the social service department many sources of infection have been located and the patients placed under treatment. A total of 305 cases have been handled for the quarter. This work is being inaugurated in the towns throughout the state. The quarantine power of the board in venereal cases has been upheld in the district court in Minneapolis.

MISSOURI

Banquet to Society.—Dr. Charles R. Woodson, St. Joseph, was host at the sixth annual dinner of Buchanan County Medical Society, which was held at the Woodson Sanatorium, South Park, St. Joseph.

Tuberculosis Cottage Ready.—The new cottage erected by the health board of St. Joseph, on a site near the City Isolation Hospital, for the treatment of patients with tuberculosis has been completed and is ready for occupancy. The building is a one-story structure, 42 by 16 feet, and is divided into two large rooms for patients, a hallway and living room combined, and a bathroom and diet kitchen. The building will accommodate ten patients.

Personal.—Dr. Ellsworth H. Trowbridge, Kansas City, formerly in charge of medical inspection in the public schools, has been appointed acting assistant surgeon, U. S. P. H. S., and assigned to duty in the Kansas City district.——Dr. Milton P. Overholser, Harrisonville, who has been ill with septicemia in St. Mary's Hospital, Kansas City, is reported to be convalescent.——Dr. William J. Hunt, St. Joseph, has resigned as physician of Buchanan County to enter the military service.

NEW YORK

Infantile Paralysis.—It is reported that there are seventy-seven mild cases of infantile paralysis in the village of Alfred. None of the cases are said to be serious.——Hornell reports fourteen cases of the disease.

First District Branch Elects.—The First District Branch of the Medical Society of the State of New York held its twelfth annual meeting at Tuxedo, October 17, and elected the following officers: president, Dr. Joseph B. Hulett, Middletown; first vice president, Dr. George A. Leitner, Piermont; second vice president, Dr. Edward C. Rushmore, Tuxedo Park; secretary, Dr. Charles Ellery Denison, New York, and treasurer, Dr. John A. Card, Poughkeepsie.

New York Infirmary for Women and Children Appeals for Funds.—This institution is making renewed efforts to secure the $200,000 which is required to enable it to go on with its work. It is sixty-five years since the institution was established, and it has never before been compelled to appeal to the general public for aid. During the last year the infirmary has cared for more than 700 mothers and new-born infants, has performed 643 operations, and has treated 53,000 cases in its clinic.

Personal.—Dr. Bertis R. Wakeman, Hornell, has been appointed city health officer of Hornell, to succeed Dr. John A. Conway, Hornell, who has resigned to accept a commission in the Medical Corps.——Dr. Henry S. Stillwell, Ogdensburg, who has been ill with pneumonia, is reported to be convalescent.——Dr. Abram W. Stoutenberg, Binghamton, has been appointed physician and manager of the Boone County Tuberculosis Hospital, to succeed Dr. William A. Behan, Binghamton, who has resigned to enter the government service.

Loses License.—The board of regents of the University of the State of New York filed in the office of the clerk of Bronx County, October 2, a certificate stating that at the meeting held Sept. 19, 1918, the medical license of Dr. Edgar S. Bullis, Albany, and his registration as a practitioner was annulled. The certificate states that Dr. Bullis "was charged with and found guilty of unlawfully accepting $220, and asking for $2,880 and a diamond ring to influence his decision on a matter pending before him in his place of trust, he being at the time a captain in the United States Army, in violation of the provisions of Section 117 of the Federal Penal Code."

New York City

Clinical Meeting on Deformities.—The clinical meeting of the Hospital for Deformities and Joint Diseases was held, October 22, and Dr. Frederick Tilney discussed, "Gait and Reflexes in Cord Lesions."

Personal.—Dr. Julius Lewis Amster, former health commissioner, is suffering from blood poisoning contracted while operating a few days ago. He is reported to be out of danger.——Dr. William H. Park is seriously ill with influenza.

New Health Zone for Mothers.—A new branch of the Maternity Center Association has been opened at 412 West Forty-Seventh Street, in Health Zone No. 5, which includes that part of Manhattan between Twenty-Sixth and One Hundred and Fifth streets.

School Lunches Approved.—The plan of the board of education to provide luncheons in the public schools of the city has been approved by William Guggenheim, chairman of the Teachers' Loyalty Committee of the American Defense Society. In his letter of approval he states that "The physical health of the children is most essential for their complete mental and moral development. The custom of providing them with luncheons at the schools, therefore, will further very materially so desired an end."

Influenza Situation Serious.—The reports of the New York Health Department show that, October 19, there were 4,930 cases of influenza reported which was about 200 more than on the preceding day. It is believed that about one half the actual number of cases are being reported. While the number of cases of influenza has increased, the number of cases of pneumonia has decreased during the past few days. There has, however, been an increased number of deaths from both diseases. The hospitals of the city are sorely in need of physicians and nurses and are so overcrowded that a number of vacant residences are used for the care of victims of the epidemic. The New York Infirmary for Women and Children has turned over its building to the health department for the care of influenza patients. The Health Commissioner's Emergency Advisory Committee announces the opening of district quarters in different neighborhoods in Manhattan. Forty-two of these centers have been put in operation. This committee issued a statement, October 18, declaring that the epidemic up to that moment was under control and that there is no occasion for public alarm. They have also issued a circular of instructions. Admiral Usher, commandant of the Brooklyn Navy Yards, has issued an order forbidding Navy men to ride on the subway. An investigation by the War Department Industries Board shows that in the factories in Queens where government work is being done and where more than 25,000 persons are employed, approximately 12 per cent. of the employees were absent from work and in some of the plants the absentees ran as high as 35 per cent.

OHIO

Personal.—Dr. A. Irving Ludlow, Seoul, Chosen, Korea, formerly of the surgical staff of the Lakeside Hospital, Cleveland, has gone to Harbin, Manchuria, as a member of the American Red Cross Unit to form a hospital base for the Japanese, Czecho-Slovac forces operating along the line of the Trans-Siberian Railway.——Lieut. Daniel H. Bowman, M. C., U. S. Army, Kenton, is reported to be seriously ill at Camp Greenleaf, Ga.

District Tuberculosis Hospitals.—District tuberculosis hospitals now provide for tuberculous persons from twenty-seven counties of the state, and twenty-two other counties have taken steps to establish districts, and following that, hospitals. Preliminary steps have been taken recently by Fairfield, Licking, Coshocton, Muskingum and Perry counties to establish a hospital, making the third new district formed this year. The importance of establishing the hospitals is emphasized by the fact that already nearly 750 discharged tuberculous soldiers from Ohio have been reported to the state department of health, and of this number only twenty-seven have been admitted to sanatoriums. The number of cases among soldiers will no doubt increase as the war goes on.

PENNSYLVANIA

Tax Opposed by Physicians.—The physicians in attendance at the meeting of the Medical Society of the State of Pennsylvania are said to have gone on record as unanimously opposing a bill before Congress classing medicine as a luxury and subjecting it to a tax of 10 per cent.

Personal.—Dr. Thomas S. Blair, Harrisburg, has been appointed chief of the new Division of Control of Narcotics in the state department of health.——Dr. Aaron D. Weaver, Old Zionsville, who has been ill with influenza, is reported to be convalescent.——Dr. Conrad J. Becker, Wilkes-Barre, was run down and seriously injured by an automobile, October 1.

Ruling on License Revocation.—The attorney-general's department of the state has notified Dr. John M. Baldy, Philadelphia, chairman of the State Bureau of Medical Education and Licensure, that the bureau "has no power to revoke the license of a physician whose right to practice was obtained prior to the Act of June 3, 1911, if the offense was prior to the Act of May 24, 1912."

Influenza.—Eight Army surgeons have been sent into Dauphin County to help fight the epidemic, replacing physicians smitten with the disease, and four senior medical students have been sent to Williamstown. Members of the reserve militia are acting as orderlies in emergency hospitals at Bristol, Paoli, Nanticoke and Homestead. October 15, the Red Cross ran a truckload of drugs from Philadelphia to Pottsville. October 17, Dr. B. Franklin Royer, Harrisburg, acting commissioner of health, refused to rescind his action (closing the wholesale and retail liquor houses) or to give any date when the ban would be lifted. Richard Wood of Allan Wood Iron Company, Conshohocken, gave $5,000 for the maintenance of an emergency hospital in that town for the care of the needy influenza patients.

Philadelphia

New Dean.—Dr. Allan J. Smith has been appointed dean of the Medical Department of the University of Pennsylvania to fill the post of Dr. William Pepper.

Influenza Mortality High.—While the number of new cases of influenza has somewhat decreased, the death rate for the week ending at noon, October 19, was much higher than the previous week. The number of new cases for the week was 14,566 as compared with 20,854 for the week preceding. The death rate, however, was 4,596 as compared with 2,635. The death rate for the week from all causes reached 5,270, representing a mortality rate of 156.01 per thousand, as compared with 95.74 the week ending October 12, when Philadelphia showed the highest death rate that had ever been recorded. The total number of deaths for the three weeks during the height of the epidemic reached 10,301, of these influenza and pneumonia cases 8,578. A number of emergency hospitals have been opened. The entire main building of the Woman's Hospital at Twenty-Second Street and North College Avenue, both surgical and medical, has been turned over to caring for emergency influenza cases and all the available space has been occupied by patients. Thirty nurses have been stricken with the epidemic and two have died, but the work of caring for the suffering has not been hampered as a number of women have volunteered as nurses. One is serving as an ambulance driver in place of the regular driver who is ill. Red Cross group No. 9 has opened an emergency hospital in St. Stephen's parish house, Wissahickon. Supplies have been sent to the building from the Red Cross headquarters but the upkeep of the hospital will depend on the support of the residents of the twenty-first ward. The members of the North Philadelphia Business Men's Association rented a building at 4015 Germantown Avenue and have 100 beds. Dr. Edward H. Wiggins is the physician in charge; in South Philadelphia, where the conditions were most distressing, the South Philadelphia Republican Club at Broad Street and Snyder Avenue, was transformed into an emergency hospital capable of caring for seventy-five patients; $4,000 was contributed by the South Philadelphia business men and the patients were taken care of by a few doctors assisted by twenty fourth-year medical students. An old horse-driven ambulance was resurrected and a fireman volunteered as driver and many of the poor not only received medical attention but were supplied with food. Problems of all sorts have resulted from the epidemic: the task of feeding many families of influenza patients; of fumigating the houses where patients have died and caring for the hundreds of children left helpless by death of parents. The Division of Child Hygiene in the bureau of health is grappling with the problem of the orphaned children; the College Settlement has organized numerous squads for inspecting, cleaning and disinfecting houses, and twelve emergency food service centers have been established. The city opened an emergency hospital in the old Medico-Chirurgical Hospital and a number of physicians volunteered their services.

CANAL ZONE

Report of Health Officer on Venereal Diseases.—In his report for the quarter, April, May and June, 1918, Arthur T. McCormack, chief health officer of the Canal Zone, discusses the situation with reference to venereal diseases in the zone and offers some plans for the improvement of conditions, which he says is the greatest problem that has been presented. The matter has been the subject of conference between the health and the military authorities. Panama and Colon are within the exclusive jurisdiction of the sanitary authorities of the United States and the police jurisdiction of the Republic of Panama. Neglect of the Panama authorities to enforce any sort of regulation resulted in a great increase in venereal diseases among our soldiers and forced the commanding general of the department to issue a general order which was, in effect, a quarantine against the two cities named with reference to venereal diseases, habit forming drugs and alcohol, and to protest against the graft and incompetence which always accompany these evils. The uncertain effect of land quarantines and the undesirability of an indefinite quarantine along a boundary line between two friendly states finally resulted in the acceptance by the Panama authorities of a plan proposed by the chief health officer by which the former retained their police authority and the latter the sanitary responsibility. Prostitution is forbidden in the zone itself, prostitutes are deported, and employees contracting venereal diseases are heavily penalized, yet the chief health officer says these diseases have alternated with tuberculosis as the most common cause of hospital admission since malaria has been under control. In Panama and Colon segregated districts have existed almost since the American occupation, but there are more prostitutes outside of these districts than in them, and it is said about 90 per cent. of the patrons of the prostitutes are American soldiers, sailors and civilians. General Order No. 20, the order referred to, greatly reduced the evil, but, July 15, a decree was to become effective that every woman remaining in the segregated district, as well as the clandestines, must be examined and all those infected treated in the Santo Tomaso Hospital at the expense of the Republic of Panama. Every man applying for admission to the segregated district was to be examined by a physician, and if diseased, required to submit to treatment in or out of the hospital, at the discretion of the health officer. Ten per cent. of the men so far examined, it is said, have been found infected and treated, the indigent at the public expense. About one-third of those examined in the laboratories were found to be syphilitic, and this is said to indicate about the ratio of those infected in the population of the two cities. Under the decree house owners renting to prostitutes are fined by the health officer, and thus placing the burden of enforcement on them forces the clandestines to come to the segregated district where they are examined and treated by qualified physicians only. Druggists are forbidden to have in their possession patent medicines or other remedies for venereal diseases except such as are prescribed by physicians. Physicians are required to report all cases treated by them. The health officer suggests three plans for handling the matter: The abrogation of this decree and the issuance of a police decree enforceable in the Panama courts making all vice criminal. On account of the acceptance of illicit intercourse as a necessary evil by the Panamaians, such a decree would be even more negligible as a factor in disease prevention than it is in the United States. A second plan would be to increase the personnel of the health department by twelve physicians, four of whom should be gynecologists, and three inspectors, together with an appropriation of about $2,000 per month to Santo Tomaso Hospital to increase the force of nurses and orderlies. This, it is said, would cost between $50,000 and $75,000 a year, but would rapidly decrease venereal diseases. The third plan, and the one which the health officer at present thinks would be least satisfactory, would be to allow the old conditions to return, only increasing the personnel of the health departments of the two cities, and depending on the education of the public to hasten the elimination of these diseases. This it is said would take many years, whereas only months would be required by a more radical plan, such as the second plan outlined. The health officer fears, however, that the third plan will have to be adopted unless the money is forthcoming speedily to carry out the more radical plan.

CANADA

Hospital Opened.—The formal opening exercises of the Laval Hospital of Quebec were held at St. Foy, October 13.

Hospital News.—Fifteen municipalities throughout Alberta are taking advantage of the rural hospital legislation, and the largest hospital yet arranged for is to be at Wainwright. Vermillion, Mannville and Lacombe are also getting their organizations under way.——Soldiers discharged on account of tuberculosis are to have increased provision for their care in the western provinces, and a new sanatorium is to be erected at Bowness. Accommodation is to be arranged for from 300 to 400 patients.——Winnipeg is to erect a smallpox hospital on the grounds of the King Edward and King George hospitals.

Society Meetings.—At the annual meeting of the College of Physicians and Surgeons of the Province of Quebec, held recently in Quebec, the following officers were elected: president, Dr. Rudolphe Boulet, Montreal; vice presidents, Drs. Albert Laurendeau, St. Gabriel de Brandon; Louis Ph. Normand, Trois-Rivieres, and Arthur A. Simard, Quebec, and secretary, Dr. Joseph Gauvreau, Montreal.——At the annual meeting of the Manitoba Medical Association held in Winnipeg, recently, the following officers were elected: honorary president, Dr. Francis-X. Demers, Ste. Anne des Chenes; president, Dr. Louis S. Gendreau, St. Norbert; vice president, Dr. Fortunat LaChance, Winnipeg, and secretary-treasurer, Dr. J. Prendergast, St. Boniface.

Personal.—Major Frederick A. Cleland, Toronto, has left for the Pacific Coast where the Canadian-Siberian Force is mobilizing. He is to be medical officer to the contingent.——Capt. A. S. Hayche, R. A. M. C., has been wounded three times, and has been awarded the Military Cross.——Capt. Frank Muir Walker, M. B., R. A. M. C., received the Military Cross when Prince Arthur of Connaught recently visited Toronto.——The following officers are reported wounded: Lieut.-Col. David Donald, Victoria, B. C., C. A. M. C.; Major George S. Mothersill, D.S.O., Winnipeg, Man., C. A. M. C.; Capt. J. C. Eager, C. A. M. C., Watertown, Ont.; W J. Sobey, C. A. M. C., les Gatlos, Ont.; D. S. Campbell, C. A. M. C., Woodside, N. S.; A. E. McCusker, C. A. M. C., Regina, Sask.; F. B. Lobb, C. A. M C., St. John, N. B.——Capt. Edgar Douglas, Vancouver, B. C., has been awarded the Military Cross.——Dr. Arthur A. Simard, Quebec, has been appointed president of the Superior Council of Hygiene, to succeed the late Prof. E. P. Lachapelle.

GENERAL

Society Meeting Postponed.—The ninth annual meeting of the American Association for Study and Prevention of Infant Mortality which was to have been held at Asheville, N. C., November 11 to 14, has been postponed until further notice on account of the epidemic of influenza.

Bequests and Donations.—The following bequests and donations have recently been announced:

Lebanon, Pa., Hospital, $2,000, Eaglesville Sanatorium for Consumptives, and Jewish Hospital, Philadelphia, each $500, by the will of Solomon Asher.

College of Physicians and Surgeons, in the City of New York, $9,000 to be applied toward work in tuberculosis, from the trustees of the East River Homes Foundation; $5,000 from an anonymous donor to be used in surgical research; $1,000 each, to the funds to provide for the admission of women to the medical school, William H. Moore, Arthur Curtiss James, Elizabeth Waterbury, Forrest S. Bryden, J. M. Wallace, D. G. Reid, and F. L. Hines.

Chicago Winfield Tuberculosis Sanatorium, and Chicago Lying-In Hospital and Dispensary each $2,000, by the will of Ferdinand Silverman, Chicago.

Children's Free Hospital, Louisville, $1,500; St. Joseph Infirmary, $500, by the will of Dr. James Morrison Ray, Louisville.

Welfare Committee for Tuberculosis.—At the closing of the annual convention of the Northwest Tuberculosis Conference in Seattle, a committee was appointed to care for the welfare of victims of tuberculosis who move from state to state. This committee consists of Drs. Bolivar J. Lloyd, Seattle; Albert E. Stuht, Spokane; Mrs. Bethesda Beals Buchanan, Seattle; Major Ralph C. Matson, Camp Lewis, Portland, Ore.; Mrs. Katherine Athey, Boise, Idaho; Judge J. F. Ailshie, Boise; Frank Leclerc, Salt Lake City; Mrs. R. A. Morton, Cheyenne, Wyo., and Mrs. John Fulton, Reno, Nev.

Influenza.—For the week ending October 12, according to the report of the United States Census Bureau, statements received from forty-six cities showed that there were 6,122 deaths from influenza and pneumonia. Philadelphia led with 1,697; New York had 979; Boston, 850; Chicago, 571, and Washington, 387. Only forty deaths were reported from St. Louis and thirty-seven from Minneapolis. Of pneumonia cases there were 1,642 in New York, 938 in Philadelphia, 476 in Chicago, and 101 in Washington. The total number of cases since September 13 was, on October 12, 262,186. A report from Washington, October 15, showed improvement in the influenza situation in the army camps and the peak of the epidemic, it was hoped, had been passed. This is probably also true with reference to the civilian population of the cities of the eastern part of the country. The disease is now prevalent in every state in the Union. In Washington, D. C., the War Department and other departments have directed that no new employees be brought to the city during the epidemic. Congress has passed a bill establishing a reserve corps in the Public Health Service. If this is signed by the President, it is expected to assist in promoting the work of the Service in handling the influenza epidemic. Charge is being taken by the Public Health Service of the situation in all the large centers. A million dollars has been voted by Congress to the service to aid in carrying out measures against the disease. In Philadelphia the director of Health and Charities, Dr. Wilmer Krusen, has suggested the zoning system in employing physicians to treat influenza. This means that each patient will call a physician nearest to him in his district. October 13, the Louisiana State Board of Health estimated that there were 250,000 cases in the state. New cases reported on that date were 594. In Virginia it was estimated, October 16, that there were 200,000 cases in the state; in Connecticut, 110,000; in California 6,500 cases had been reported to October 14. October 16, new cases among the troops in camp numbered 5,680, against 6,498 the day before. Pneumonia cases were 1,895 as compared with 1,916 for the previous day. The deaths were 710, a decrease of 179. Improvement in the situation was noted in Vermont and New Jersey and in parts of Tennessee. At Davenport, Iowa, the Manufacturers' Association met with the Red Cross and arranged to equip an emergency hospital with from twenty-five to fifty beds with graduate and volunteer nurses in attendance. Ohio reported October 21, that there had been 100,000 cases in the state to that date. The state authorities were cooperating with the Public Health Service and volunteer physicians and nurses are being provided where needed. A quarter of a million circulars and leaflets on influenza have been distributed. Improvement is reported from some cities where the situation had been serious. October 22, based on reports for the previous forty-eight hours, in Chicago it was thought that the epidemic had decreased to the extent of 30 or 40 per cent. and that the peak of the epidemic had been passed, but efforts were not relaxed and everything was kept closed. For the period of forty-eight hours there were 2,700 new cases, 680 of which were of pneumonia.

FOREIGN

Italian Military Hospital at Grenoble.—The *Policlinico* states that the most important sanitary formation for the Italian troops in France has just been equipped by private gifts with a radiologic cabinet.

In Honor of Golgi.—As Prof. C. Golgi of the chair of general pathology at the University of Pavia is retiring this year on account of having reached the age limit, a committee has been formed to do him honor. It has been decided that the testimonial should take the form of a scholarship in the medical department of the University of Pavia, to be awarded preferably to the orphans of physicians, and in particular to victims of the present war. The committee includes representatives of the medical department, and the local and provincial medical organizations. Subscriptions are received by the treasurer of the Ordine dei medici della provincia di Pavia.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Deaths on a Liner.—October 7, the Spanish liner, *Alfonso XII*, arrived at a Cuban port reporting twenty-four deaths during the voyage from a malady not diagnosed, but which it is thought must be influenza. It is said that two persons among the 1,200 passengers, crazed by suffering, committed suicide. Sixty persons were ill on the arrival of the ship, forty of whom were in a serious condition.

Personal.—Dr. F. M. Fernandez, editor of the *Cronica Medico-Quirurgica* of Havana, was recently awarded the Cañongo prize by the Academia de Ciencias Medicas, Fisicas y Naturales for his work on the etiology and treatment of strabismus.——Dr. B. Saenz has been appointed to the chair of dermatology at the University of Havana after competitive examination, and Dr. M. Dominguez has been appointed chief of the National Laboratory.

MEXICO LETTER

Mexico City, Oct. 9, 1918.

Free Dispensary for Venereal Diseases

The Sociedad de Profilaxia de las Enfermedades Venereas has opened in Tacuba St., No. 78, a free evening dispensary to care for the poor with venereal disease. The work is to be done by several of the medical members of the society. Besides treating the gonorrheal and syphilitic, they will instruct in the indispensable ideas of sexual hygiene and in the evil consequences of trusting treatment to charlatans and of attempts at self treatment with the so-called specifics. A group of philanthropic persons contributed the funds to organize this dispensary, a total of 1,000 pesos, and others have offered to pay a monthly quota for its support. The society intends to give the treatments entirely free of charge with the possible exception of injections of arsphenamin and neoarsphenamin—especially the first mentioned—the price of which at present is almost prohibitive.

New Laboratory

When the public health service was reorganized last year into the Departmento de Salubridad Publica, the bacteriologic laboratory, which was one of the features of the old Consejo de Salubridad, was suppressed. This laboratory was due to the initiative of Dr. E. Liceaga, at that time president of the Consejo de Salubridad and it aided in the diagnosis of typhoid fever, malaria, diphtheria and tuberculosis, besides its other work, all free of charge to the public. As the effects of the lack of such an institution are being felt, it is now proposed to reopen it, and henceforth the laboratory will make pathologic, bacteriologic and chemical analyses as before and in addition the Wassermann fixation test. The directors of the laboratory are to be Drs. Amerena and Garduño Soto.

"Allied Notes"

As at present there are no papers published in English in Mexico City, the *Universal*, the daily with the largest circulation in Mexico, which has always been friendly to the Allies, has commenced to publish a section entitled "Allied Notes" or "Comments," in which items of interest for the members of the North American and British colonies here are published in English, and the philanthropic and welfare work which they are doing is recorded. Lately the ladies of these colonies have been making clothing for Belgian and French orphans whose fathers have sacrificed their lives on the altars of progress and human civilization.

The French colonies are not mentioned in these "Notes," as they already have a daily and biweekly, published in French. Until 1915, the *Mexican Herald* was published here by Señor P. Hudson.

Typhus in Uruapan

It has been reported that the city of Uruapan, in the state just west of the capital, is being scourged with *tabardillo*. The federal sanitary authorities have taken the necessary steps to stamp out the disease.

Antirabies Institutes

The public health authorities are contemplating the establishment of several antirabies institutes throughout the country as the one in the capital is unable to care for all who require treatment, especially in remote districts not connected by railroad with the capital. In such cases it is extremely difficult for persons who have been bitten by a rabid animal to get treatment in time, especially the indigent. During August, ninety-one persons were given treatment at the institute here. Since then the brains from several rabid animals have been sent to Toluca to initiate the inoculation treatment in that neighboring city.

Medical Service in the Emergency Stations

Measures have recently been taken to improve the medical and surgical service in the Comisarias de Policia where the victims of accidents or crimes are tended and registered, and to which the indigent apply who are seeking admission to the public hospitals. Until now these services have been inadequate for the needs of the populace.

Delegates to Child Welfare Congress

The second Congreso Americano del Niño is to be held at Montevideo in December, and Señor A. Nervo, diplomatist and author, and the Mexican consul at Montevideo have been appointed to represent the Republic of Mexico at that meeting. They are to present the articles prepared by Mexican physicians. It was previously rumored that Dr. E. Aragon, the professor of legal medicine here, was to have been the official delegate.

Influenza

News has been received that influenza is prevailing in epidemic form in the states of Coahuila, Nuevo Leon and Tamaulipas, bordering on Texas, and it is feared that railroad communication between Mexico and the United States may be impeded by the sanitary police measures that may have to be taken to isolate the epidemic focus.

New Professor of Chemistry

The pharmacist, M. de M. y Campos has been appointed to the chair of chemistry in the pharmacy department of the University here after competitive examination of three candidates.

Academy of Medicine

The Academia Nacional de Medicina resumed its sessions October 2, after the regular vacation. Dr. R. E. Cicero, of the dermatology section, now presides at the meetings, and Dr. D. Lopez is the secretary. Dr. E. Montaño, of the ophthalmology section, was elected vice president and Dr. M. E. Soberon second secretary.

LONDON LETTER

London, Sept. 17, 1918.

The Shortage of Medicinal Oils and Fats

A committee appointed by the Home Office on the outbreak of war to deal with economy in the use of drugs has issued a memorandum to the medical profession on measures necessary to meet shortage or discontinuance of the supply of lard, olive oil and castor oil for medicinal purposes. The prior claims, partly of food supply and partly of munition production, have for some months compelled restriction or even discontinuance of these substances for medicinal purposes. At present lard can no longer be released for medicinal use. The amount of olive oil and of the possible substitutes, sesame and arachis oils, that can be released is uncertain. Little if any of the quality of castor oil hitherto required for conformity with the pharmacopeial standard can be used. To obviate the difficulties that might have arisen through the fact that these substances are ingredients of many official preparations, the General Medical Council, after consultation with the Home Office Committee, directed, in an alteration and amendment of the British Pharmacopeia, 1914, that certain preparations be withdrawn from the British Pharmacopeia until further notice, while in the case of other preparations containing oils and fats, the use of various substitutes was sanctioned. By these alterations, considerable latitude was accorded in the dispensing of prescriptions that contained the official preparations affected. It appeared desirable, therefore, that some understanding should be established between prescribers and dispensers that should obviate uncertainty, and it seemed that this would best be effected by the suggestion of alternative preparations of definite formulas. The Pharmaceutical Society, acting in cooperation with a body of representative manufacturers and the Home Office Committee, undertook the necessary experiments, and has now constructed a set of war emergency formulas. The following suggestions are offered for the assistance of physicians in prescribing:

Lard can no longer be dispensed either as such or as an ingredient of a prescription. A base consisting of 5 per cent. wool fat, 10 per cent. hard paraffin [paraffin] and 85 per cent. soft paraffin [petrolatum] is on the market, and will, it is believed, afford a suitable substitute for most cases in which lard would previously have been ordered. For some cases the physician may find it advisable to modify the proportions of the ingredients named. Ointments formerly containing lard or lard and suet are now allowed to be prepared with wool fat or paraffin or mixtures of these in place of the lard or lard and suet, which may no longer be used. The base described above (named for convenience adeps factitius) has been found to afford a satisfactory substitute in the preparation of these ointments, and war emergency formulas containing it have been constructed.

For olive oil, sesame oil or arachis oil may be substituted, but none of these vegetable oils should be ordered avoidably. When required for external purposes a specially prepared mineral oil derived from petroleum (known as paraffinum liquidum flavum) is now obtainable, and will in most cases be found to afford a satisfactory substitute.

Four liniments containing olive oil have ceased to be official. War emergency formulas, containing the specially prepared mineral oil mentioned above, have been devised Liniments so prepared are on the market and may be substituted for the former official preparations.

For castor oil it has been found that the neutralized seconds castor oil, now recognized by the pharmacopeia and readily obtainable, affords a satisfactory substitute for the first quality oil hitherto used. One preparation containing castor oil has been withdrawn, namely, liquor cresol saponatus. For the preparations containing castor oil remaining official, collodium flexile, linimentum sinapis, and liquor epispasticus, the neutralized second oil will be used.

The Sinking of the Llandovery Castle

The results of an inquiry by the Minister of Overseas Military Forces in Canada Sir Edward Kemp, into the sinking of the hospital ship *Llandovery Castle*, June 27, are published in the August number of the *Bulletin* of the Canadian Army Medical Corps. Two facts stand out—the devotion and sacrifice of the medical personnel and the ship's company, and the dastardliness of the outrage. "Deliberate in its conception, every circumstance reveals the German in the light of the cunning murderer who employs every foul means of destroying all traces of his crime. No other explanation can be attached to the systematic attempts of the submarine to ram, shell and sink the lifeboats and wreckage floating helplessly with their 258 victims 116 miles from land—a work of destruction so successfully performed that only one boat containing twenty-four survivors escaped." The ship had been in service for the Canadian government as a hospital ship since March, 1918, and made four voyages to Halifax. She was on her return voyage carrying the crew and hospital establishment, but no patients nor any passengers. The statement of the submarine commander that she carried American flying officers or munitions is simply the usual convenient fiction of the Hun. There were no grounds whatever for mistaking her for anything else than a hospital ship. Except one medical officer, a sergeant and four privates, all the medical personnel were lost, including the commanding officer, Lieutenant-Colonel Macdonald of Nova Scotia.

PARIS LETTER

Paris, Sept. 19, 1918.

Health Conditions in France

The Conseil supérieur d'hygiène, at its last session, considered reports furnished by the director of the Assistance et Hygiène publiques au ministère de l'intérieur, and the representatives of the office of the Service de Santé militaire and of the Service de Santé de la marine on health conditions in France. The *Conseil* verified the statements that while there are many small foci of grip in various parts of the country, as is also the case in Algiers, in the colonies, and in most foreign countries, and although, owing to the severe heat, dysentery has made its appearance anew in French territory, yet there has not been a single case of typhus, plague or cholera.

Heated Air in the Treatment of War Wounds

Drs. Belot and Dechambre reported to the Société médico-chirurgical de la XIII-e Région the good results which they have obtained from the treatment of war wounds with a jet of hot air. The temperature of the air varied between 60 and 80 C., with a pressure of 4 or 5 kilograms. It is well to combine this treatment with massage of the surrounding and subjacent tissues. The heated air dries the wound, the odor disappears, and dead tissue is thrown off. The surface becomes rosy in hue, small granulations form, and epidermization takes place, extending from the periphery toward the center. The duration of the treatment varies from one to three months. About 600 cases which have resisted the usual methods of treatment have been treated by Belot and Dechambre in the manner described, with only 5 or 6 per cent. of failures, generally restricted to cases associated with severe trophic lesions.

Treatment of Ulcers

Several surgeons have had good results from the treatment of wounds with balsam of Peru, which is a good deodorizer, antiseptic and keratoplastic. Dr. Morlet uses the balsam especially in the treatment of ulcers. In order to lessen the discharge of pus from the wound and to prevent its stagnation in the wound, he mixes bismuth subnitrate with the balsam, making an absorbent paste of the mixture when it has dried. In this manner a sort of embalming dressing is obtained, which is semi-occlusive and yet at the same time permits the pus to escape from the wound, and then acts as a drier. The mixture contains 15 to 20 gm. of balsam of Peru; the same amount of bismuth subnitrate; 50 gm. of *colle de poisson* (gelatin); 50 gm. of glycerin and 100 gm. of water. The *colle de poisson* should be used in preference to any other gelatin, which may be infected with tetanus bacillus spores. The wound is cleaned with alcohol and the paste is applied by means of strips of tarletan which have been impregnated with the heated paste. They are then placed over the wound in the same manner as is a silicate bandage. This dressing is left in place for from twelve to fifteen days. According to the size of the wound, one or two dressings only are necessary, rarely a third. The patient is permitted to be up and about, thus adding mechanical action from walking to the keratoplastic and drying qualities of the paste.

Emetin and Ipecac

Since subcutaneous injections of emetin hydrochlorid have established a place for this agent in the treatment of amebic dysentery, other indications for its use have been found, notably in the treatment of hemoptysis, pulmonary congestion, etc. In this connection attention should be directed to the danger attending the use of ipecac even in infinitesimal doses, in cases in which emetin has been previously used. Drs. G. Billard and Blatin have made some interesting observations in this respect. In twelve cases of amebic dysentery of severe type, in which the emetin seemed to have exhausted its efficiency, it was thought advisable to resort to the use of ipecac, administered according to the Brazilian method. In order to determine the susceptibility of the patient to ipecac, 0.05 gm. of powdered ipecac was administered. In each instance, in a few minutes, the patient became pale, nauseated and then vomited; in four cases cardiovascular symptoms appeared, with syncope of short duration; in one instance these symptoms became alarming, an actual narcoleptic state ensuing and lasting for more than eight hours.

Marriages

Lieut. Claude Everett Brown, Assistant Surgeon, U. S. Navy, Sacramento, Calif., on duty at the U. S. Naval Transport Depot, New York City, to Dr. Alice Cornelia Scully of Springfield, Mass., September 26.

Lieut. Robert Percival Parsons, Assistant Surgeon, U. S. Navy, Chicago, on duty at Deer Island, Boston, to Miss Marion L. Murray of Allston, Boston, recently.

Lieut. Leo L. Smith, M. C., U. S. Army, Sapulpa, Okla., on duty at Camp Pike, Ark., to Miss Mabel E. Robison, at Sapulpa, August 22.

Lieut. James Leonard Reycraft, Assistant Surgeon, U. S. Navy, Cleveland, to Miss Marie Dannemiller, also of Cleveland, October 2.

Lieut. Stanley Joseph Seeger, M. C., U. S. Army, Milwaukee, to Miss Helen Brachman of Texarkana, Texas, October 8.

John Arthur Foley, Dorchester, Boston, to Miss Elizabeth Ewing of Roxbury, Boston, recently.

Deaths

Frank Fairchild Wesbrook, Vancouver, B. C.; Manitoba Medical College, Winnipeg, 1890; aged 50; a Fellow of the American Medical Association; president of the University of British Columbia, Vancouver, since 1913; died at his home, October 21. He was formerly professor of pathology and bacteriology in the University of Manitoba; professor of pathology and bacteriology in the Medical School of the University of Minnesota from 1895 to 1913, and dean of the institution from 1906 to 1913; director of laboratories of the Minnesota State Board of Health from 1896 to 1911, and member of the board from 1896 to 1900, and from 1911 to 1912; a member of the advisory board of Hygienic Laboratory, U. S. P. H. S., from 1904 to 1913; president of the American Public Health Association in 1905; president of the section on state and municipal hygiene of the International Congress of Hygiene and Demography in 1912; chairman of the provincial committee on food resources, and a member of many learned societies of the United States, Canada and Europe.

Frank Baker, Washington, D. C.; George Washington University, Washington, D. C., 1880; aged 77; a Fellow of the American Medical Association; professor of anatomy of Georgetown University since 1883; for many years lecturer on artistic anatomy at the Corcoran Art Gallery; superintendent of the National Zoological Park from 1886 to 1916; president of the Association of American Anatomists in 1897; and once vice president of the American Association for the Advancement of Science; assistant superintendent of the U. S. Life Saving Service from 1889 to 1890; editor of the *American Anthropologist* from 1891 to 1898; died at his home, about September 30.

Died in the Service
Asst. Surg. Hadley H. Teter, Lieutenant, U. S. Navy, 1891-1918
(See The Journal last week, p. 1334)

Died in the Service
in France
Lieut. Irving J. Pinkus, M. C., U. S. Army, 1891-1918

Died in the Service
in France
Lieut. Emil King, M. C., U. S. Army, 1867-1918

Frederick Carroll Heath, Indianapolis; Bowdoin Medical School, Brunswick and Portland, Me., 1884; aged 61; at one time a Fellow of the American Medical Association; secretary of the Indiana State Medical Society from 1896 to 1910, and president in 1910, and president of the Indianapolis Medical Society in 1905; eye surgeon to the Indianapolis City Hospital and Dispensary, the German Lutheran Orphan Asylum and Eleanor Hospital; professor of ophthalmology in the Indiana University Medical College since 1905; at one time assistant surgeon in the U. S. P. H. and M. H. S.; died at his home, October 16. .

Lieut. Herbert Douglas Taylor, M. C., U. S. Army, New York City; Johns Hopkins University, Baltimore, 1914; aged 29; a Fellow of the American Medical Association; for three and one-half years a member of the scientific staff of the Rockefeller Institute; an instructor in parasitology in the officers' school at that place, and in charge of the laboratory of the War Demonstration Hospital; also instructor to the surgical staff in bacteriology of wounds; an investigator of great talent and promise; died in the Rockefeller Hospital, New York, October 7, from pneumonia, following influenza.

Clarence Hamilton Gray, Philadelphia; University of Pennsylvania, Philadelphia, 1905; Hahnemann Medical College, Philadelphia, 1915; aged 35; at one time a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; chief of the staff of the Maternity Hospital and a member of the ophthalmological staff of the Hahnemann Hospital, Philadelphia; died at his home, October 6.

Herbert Marion Stowe, Chicago; Rush Medical College, 1896; aged 44; a Fellow of the American Medical Association; assistant professor of obstetrics in Northwestern University Medical School; assistant obstetrician to Provident Hospital; attending obstetrician to the Chicago Lying-In Hospital, and a member of the staffs of Cook County and Mercy hospitals; died, October 21, from appendicitis.

Asst. Surg. Bronson Ewing Summers, Lieutenant (Junior Grade), U. S. Navy, Richmond, Va.; Medical College of Virginia, Richmond, 1912; aged 28; a Fellow of the American Medical Association; at one time assistant health officer of Richmond; on duty with the United States Marine Corps at Quantico, Va.; died in the hospital of that camp, October 12, from pneumonia, following influenza.

Lieut. Nial Franklin Twigg, M. C., U. S. Army, Brockton, Mass.; Johns Hopkins University, Baltimore, 1917; aged 25; who had been connected with a base hospital at Birmingham, England, was returned to the United States about six months ago, and was assigned to duty at Fort Oglethorpe, Ga.; died in General Hospital No. 14, Fort Oglethorpe, October 10, from pneumonia, following influenza.

Lieut. Emil King, M. C., U. S. Army, Fulda, Minn.; University of Pennsylvania, Philadelphia, 1893; aged 51; a Fellow of the American Medical Association and a specialist on diseases of the ear, nose and throat; on duty with the American Expeditionary Forces in France, is reported to have been killed in action, about October 7.

Lieut. Irving Jonas Pinkus, M. C., U. S. Army, New York City; University and Bellevue Hospital Medical College, 1914; aged 27; a Fellow of the American Medical Association; is reported to have been killed in action, August 31.

John Wesley Kinard, Lancaster, Pa.; University of Maryland, Baltimore, 1882; Bellevue Hospital Medical College, 1889; aged 60; a Fellow of the American Medical Association, and once president of the Lancaster City and County Medical Society, and Lancaster Pathological Society; local physician of the Pennsylvania Railroad; died at his home, October 8, from pneumonia.

Major Clarence Fahnestock, M. C., U. S. Army, New York City; College of Physicians and Surgeons in the City of New York, 1900; aged 45; a Fellow of the American Medical Association; chief surgeon of the Three Hundred and First Infantry, at Camp Devens, Ayer, Mass., and later on duty as a line and medical officer in France; died, October 5, from pneumonia.

Capt. Warren Walker, M. C., U. S. Army, Philadelphia; University of Pennsylvania, Philadelphia, 1900; aged 39; a Fellow of the American Medical Association; surgeon to the outpatient departments of the Episcopal and Children's hospitals; was burned to death in the fire which consumed the officers' quarters at U. S. Base Hospital No. 3, Colonia, N. J., October 9.

Adolph Cohn, Philadelphia; Medico-Chirurgical College of Philadelphia, 1913; aged 26; at one time a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; surgeon to the Baldwin Locomotive Works, and draft board examiner; died at the Jefferson Hospital, October 7, from pneumonia, following influenza.

Paul Guilford, Chicago and LaGrange, Ill.; University of Pennsylvania, Philadelphia, 1891; aged 48; a Fellow of the American Medical Association; attending oculist and aurist to St. Luke's Hospital, Chicago; a well known specialist on diseases of the eye, ear, nose and throat; died at his home in LaGrange, October 20, from pneumonia, following influenza.

Lieut. Clayton A. Endicott, M. R. C., U. S. Army, Frankfort, Ind.; State College of Physicians and Surgeons, Indianapolis, 1907; aged 37; a Fellow of the American Medical Association, and secretary of the Clinton County Medical Society; secretary of the Frankfort Board of Health; died at his home, October 8, from pneumonia, following influenza.

James Christopher Wallis, Arkadelphia, Ark.; Jefferson Medical College, 1877; aged 64; a Fellow of the American Medical Association; president of the State Medical Board of the Arkansas Medical Society, and of the Arkansas Medical Society in 1915; and once president of the Clark County Medical Society; died at his home, October 10.

Lieut. Carl Calvin Culver, M. C., U. S. Army; Burlington, Kan.; University of Kansas, Lawrence and Rosedale, 1911; aged 31; a Fellow of the American Medical Association; on duty at Camp Grant, Rockford, Ill.; a specialist on diseases of the eye, ear, nose and throat; died in Camp Grant, about October 6, from pneumonia, following influenza.

Capt. Charles Emmett Varier, M. R. C., U. S. Army, South Bend, Ind.; University of Michigan, Ann Arbor, 1909; aged 34; a Fellow of the American Medical Association, and for one year president of the St. Joseph County Medical Society; under orders to preceed to Camp Zachary Taylor, Louisville; died at his home, October 9, from pneumonia.

Michael Francis Black, New York City; College of Physicians and Surgeons in the City of New York, 1904; aged 40; a member of the Medical Society of the State of New York; attending physician to the Seton Hospital, and chief surgeon to St. Vincent's Hospital, New York City; died at St. Vincent's Hospital, October 5, from pneumonia.

John Joseph Hassett, Lee, Mass.; New York University, New York City, 1887; aged 56; a Fellow of the American Medical Association, and president of the Berkshire County Medical Society; associate medical examiner of Berkshire County; a member of the school board of Lee; died at his home, October 11, from pneumonia.

Lieut. James Allen Etheridge, M. R. C., U. S. Army, Baltimore; Johns Hopkins University, Baltimore, 1916; aged 26; who had spent several months in Flanders with the Johns Hopkins Unit, and was later under treatment for injuries in a hospital in London; died in Johns Hopkins Hospital, Baltimore, October 7, from influenza.

Asst. Surg. John Clinton Bowman, Lieutenant, U. S. N. R. F., Canton, Ohio; Ohio State University, Columbus, 1918; aged 28; a Fellow of the American Medical Association; formerly a practitioner of Thornville, Ohio; died in the U. S. Naval Hospital, Philadelphia, October 2, from pneumonia, following influenza.

John Farrar Hunter, Jackson, Miss.; Tulane University, New Orleans, 1882; aged 58; a Fellow of the American Medical Association; for several years secretary and executive officer of the Mississippi State Board of Health; one of the most prominent physicians of the state; died at his home, October 5, from heart disease.

Harry Burton Stevenson, Baltimore; University of Maryland, Baltimore, 1892; aged 48; at one time a member of the Medical and Chirurgical Faculty of Maryland; president of the Baltimore County Medical Association, and health officer of Baltimore County; died in St. Agnes' Hospital, Baltimore, October 10, from influenza.

Alfred William Berr, Rockville, Conn.; Tufts College Medical School, Boston, 1916; aged 30; formerly a member of the staff of the Lawrence (Mass.) General Hospital; who had been inducted into service and was on duty at Fort Slocom, N. Y.; died in that place, October 8, from pneumonia, following influenza.

Harold R. Dwyer, Chicago, Rush Medical College, 1895; aged 49; at one time a member of the Illinois State Medical Society; an officer of the city health department for sixteen years; high physician of Illinois, United Order of Foresters; died at the Contagious Disease Hospital, Chicago, October 20, from diphtheria.

Charles R. Schoemaker, Baltimore, College of Physicians and Surgeons, Baltimore, 1891; aged 46; at one time a member of the Medical and Chirurgical Faculty of Maryland; a member of the staff of the Presbyterian Eye, Ear, Nose and Throat Hospital, Baltimore; died at his home, October 6, from influenza.

Asst. Surg. Warren A. Van Derveer, Lieutenant (Junior Grade), U. S. Navy, Philadelphia and Mount Holly, N. J.; Hahnemann Medical College, Philadelphia, 1910; aged 31; a Fellow of the American Medical Association; on duty at Portsmouth, Va.; died in the U. S. Naval Hospital in that place, October 7.

Asst. Surg. Michael James Carroll, Lieutenant (Junior Grade), U. S. Navy, Lenox, Mass.; Georgetown University, Washington, D. C., 1910; aged 36; a Fellow of the American Medical Association; on duty at the U. S. Naval Hospital, Newport, R. I.; died in that institution, September 29, from pneumonia.

Myron Allen Boor, Terre Haute, Ind.; Medical College of Indiana, Indianapolis, 1894; aged 46; at one time a Fellow of the American Medical Association; a member of the Indiana State Medical Association; surgeon to St. Anthony's Hospital for more than eighteen years; died at his home, October 9.

Lieut. Hugh Todd Ryan, M. C., U. S. Army, Schuylkill Haven, Pa.; Hahnemann Medical College, Philadelphia, 1914; aged 26; a Fellow of the American Medical Association; on duty at Fort Oglethorpe, Ga.; died in General Hospital No. 14, at that post, October 9, from pneumonia, following influenza.

Act. Asst. Surg. Edward Raymond DeBoth, U. S. P. H. S., Green Bay, Wis.; Rush Medical College, 1911; aged 32; a member of the State Medical Society of Wisconsin; who had applied for and was awaiting commission in the Army; died at his home, October 6, from pneumonia, following influenza.

Thomas Weaver, Nashville, Tenn.; University of Nashville, Tenn., 1897; aged 45; at one time a Fellow of the American Medical Association; for several years attending physician at the Tennessee Industrial School; died in St. Thomas' Hospital, Nashville, October 6, from pneumonia.

Charles Votteler Dorwarth, Philadelphia; University of Pennsylvania, Philadelphia, 1910; aged 31; a Fellow of the American Medical Association; visiting physician to the Polyclinic and Children's hospitals, Philadelphia; died at his home, October 8, from pneumonia, following influenza.

Capt. Howard Bigelow Jackson, M. C., U. S. Army, Melrose, Mass.; Harvard Medical School, 1901; aged 44; a Fellow of the American Medical Association; on duty at Fort Oglethorpe, Ga.; died in the General Hospital at that post, October 13, from pneumonia, following influenza.

Asst. Surg. Douglas Holmes Warner, Lieutenant, U. S. N. R. F., Portland, Ore.; University of Oregon, Portland, 1918; aged 27; a Fellow of the American Medical Association; died in the U. S. Naval Hospital, Bremerton, Wash., October 8, from pneumonia, following influenza.

Felix G. Cross, Cincinnati; Miami Medical College, Cincinnati, 1869; aged 76; president of the Columbia Life Insurance Company; a veteran of the Civil War and for several years surgeon at the Dayton Soldiers' Home; died at his home, October 1, from heart disease.

William Atlee Drysdale, Philadelphia; Jefferson Medical College, 1882; of national repute as a consulting engineer;

a member of the board of examiners of the International Electrical Exhibition, Philadelphia, 1904; died at his home, October 6, from a nervous breakdown.

Arnold Robert Moon, Williamsburg, Iowa; State University of Iowa, Iowa City, 1910; aged 32; a Fellow of the American Medical Association, and secretary of the Iowa County Medical Society; died at his home, October 6, from pneumonia, following influenza.

John Knight Bennett, Gloucester City, N. J.; Jefferson Medical College, 1887; aged 61; a member of the Medical Society of New Jersey; medical inspector of the board of health of Gloucester; died at his home, October 1, from pneumonia.

Robert Earl Harrington, Montville, Conn.; Baltimore Medical College, 1906; aged 34; a Fellow of the American Medical Association; died in the Backus Hospital, Norwich, Conn., September 23, from pneumonia, following influenza.

Joseph David Cohn, Corpus Christi, Texas; Johns Hopkins University, Baltimore, 1911; aged 30; a Fellow of the American Medical Association; and a specialist in genito-urinary diseases; died at his home, September 30, from pneumonia.

John Edward West Thompson, Bridgeport, Conn.; Yale University, New Haven, 1883; aged 68; United States minister to Hayti, under President Cleveland; was stabbed by a former patient at Bridgeport, October 6, and died instantly.

Frances N. Baker, Media, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1877; aged 78; a Fellow of the American Medical Association; died in the Woman's Hospital, Philadelphia, September 29, from pneumonia.

George August Colin, Chicago; Illinois Medical College, Chicago, 1903; aged 37; a Fellow of the American Medical Association; also a druggist; died at his home, October, 10, from bronchial pneumonia, following influenza.

William J. K. Kline, Greensburg, Pa.; Long Island College Hospital, Brooklyn, 1863; aged 82; a Fellow of the American Medical Association; died in the Westmoreland (Pa.) Hospital, October 6, from pneumonia.

Hugh B. Reynolds, Escanaba, Mich.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1886; aged 53; a member of the Michigan State Medical Society; died at his home, October 3, from myocarditis.

Julius Bachrach, Joliet, Ill.; Jenner Medical College, Chicago, 1912; Chicago College of Medicine and Surgery, 1912; aged 40; a Fellow of the American Medical Association; died at his home, October 7, from pneumonia.

Frederick Joseph Denning, South Boston; Harvard Medical School, 1908; aged 33; a Fellow of the American Medical Association; died in the Boston City Hospital, September 17, from pneumonia, following influenza.

Clarence Ayers Turner, Middle Point, Ohio; Cleveland-Pulte Medical College, Cleveland, 1913; aged 31; a member of the Ohio State Medical Association; died at his home, October 4, from bronchial pneumonia.

Joseph Franklin Miller, Stroudsburg, Pa.; Medico-Chirurgical College of Philadelphia, 1906; aged 35; a member of the Medical Society of the State of Pennsylvania; died at his home, September 29, from pneumonia.

Jasper N. Clark, Columbus, Ohio; Starling Medical College, Columbus, 1872; aged 74; for thirty-five years a practitioner of Fayette County, Ohio; died at his home, September 29, from cerebral hemorrhage.

Gustavus P. Folks, Waycross, Ga.; Louisville (Ky.) Medical College, 1889; aged 60; at one time a member of the Medical Association of Georgia; died at his home, September 23, from nephritis.

Talcott Ormsbee, Stanley Station, Ore.; American Eclectic Medical College, Cincinnati, 1876; aged 83; died in St. Vincent's Hospital, Portland, Ore., September 11, from shock, following prostatectomy.

Lieut. Morris Finkelberg, M. C., U. S. Army, Spring Valley, Ill.; Loyola University, Chicago, 1908; aged 31; a Fellow of the American Medical Association; was killed in action in France, September 15.

George Wilds Linn, Malvern, Pa.; University of Pennsylvania, Philadelphia, 1872; aged 74; a Fellow of the American Medical Association; a veteran of the Civil War; died at his home, September 26.

Silas Baldwin, Baltimore; University of Maryland, Baltimore, 1867; aged 71; for more than twenty-five years coroner of northwest Baltimore; died at his home, October 2, from cerebral hemorrhage.

A. U. Gressett, Chunkey, Miss. (license, Mississippi); surgeon in the Confederate service during the Civil War; a practitioner for 57 years; died at his home, September 21, from senile debility.

Irving Harry Kaufman, Brooklyn; University and Bellevue Hospital Medical College, 1912; aged 31; adjunct visiting gynecologist to Zion Hospital; died at his home, October 1, from pneumonia.

Louis H. Geiger, Gilman, Ill.; University of Illinois, Chicago, 1903; aged 45; a member of the Illinois State Medical Society; died at St. Luke's Hospital, Chicago, October 9, from diabetes.

David Borger, Hamilton, Ohio; Eclectic Medical Institute, Cincinnati, 1876; aged 75; was found dead from cerebral hemorrhage in a cornfield in his farm, near Hamilton, September 30.

Robert C. Mitchell, Belvidere, Ill.; Chicago Homeopathic Medical College, 1901; aged 49; a Fellow of the American Medical Association; died at his home, October 7, from pneumonia.

William Robert Cluness, Alameda, Calif.; Queens University, Kingston, Ont., 1859; aged 82; at one time a Fellow of the American Medical Association; died at his home, September 26.

Harry William Priem, Chicago; Rush Medical College, 1914; aged 30; a Fellow of the American Medical Association; died at his home, October 9, from pneumonia, following influenza.

Jane Darling Stevenson, Akron, Ohio; University of Michigan, Ann Arbor, 1918; aged 25; an intern in the Philadelphia General Hospital; died in Philadelphia, October 6, from influenza.

John J. Laurans, New Orleans; Tulane University, New Orleans, 1886; aged 56; a Fellow of the American Medical Association; died at his home, September 21, from angina pectoris.

Ray Howard Rice, Delavan, Wis.; Bennett Medical College, Chicago, 1898; aged 44; a Fellow of the American Medical Association; died at his home, October 2, from pneumonia.

William Reginald Chipman, Chelsea, Boston; Harvard Medical School, 1876; aged 69; a member of the Massachusetts Medical Society; died at his home, October 7, from heart disease.

Lieut. Joseph Charles Monnier, M. C., U. S. Army, Cleveland; Western Reserve University, Cleveland, 1917; aged 28; died in Washington, D. C., October 2, from pneumonia.

Lucy Wadsworth Tuck, Boston (license, Massachusetts, years of practice, 1894); aged 90; died at the Home for Aged Women, Roxbury, Boston, September 19.

George W. Farrow, Kansas City, Mo.; Rush Medical College, 1875; aged 76; a Fellow of the American Medical Association; died at his home, September 14.

Morris Weinberg, Philadelphia; University of the South, Sewanee, Tenn., 1904; aged 37; died at his home, October 1, from pneumonia, following influenza.

Florence B. Power, Burlingame, Calif.; Willamette University, Salem, Ore., 1893; aged 50; died in San Francisco, September 29, from carcinoma uteri.

John E. Allder, Cane Hill, Mo.; Kentucky School of Medicine, Louisville, 1876; aged 75; a veteran of the Civil War; died suddenly, September 26.

Horace N. Marvin, Dover, Del.; formerly of Sioux City, Iowa; Hahnemann Medical College, Chicago, 1883; aged 73; died at his home, September 29.

Carl Clifton Stevens, Iron Mountain, Mich.; University of Michigan, Ann Arbor, 1903; aged 37; died at his home, September 30, from pneumonia.

Isaac H. Hague, Shreve, Ohio; University of Wooster, Cleveland, 1868; aged 77; a veteran of the Civil War; died at his home, September 28.

William S. Pitts, New York City; Rush Medical College, 1868; aged 88; died at the home of his son in New York City, about September 26.

William John Truitt, Naperville, Ill.; Hahnemann Medical College. Chicago, 1889; aged 51; died at his home, October 2, from pneumonia.

James F. Doyle, Santa Ana, Calif.; University of Illinois, Chicago, 1886; aged 60; died at his home, October 1.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SULPHERB

"Sulpherb" or "Sulpherb Tablets" is another of the multifarious nostrums sold by the Blackburn Products Company of Dayton, Ohio. In common with their class, they are advertised by the "fake prescription" method, a scheme which gives the reader the impression that the advertisement is really a newspaper "health department." The individual used by the Blackburn concern to carry out this deceit is Lewis Baker, whose activities in this connection we have previously noted. The advertisements appear under the general title, "The Doctor's Advice, by Dr. Lewis Baker." Here are samples of the method by which the public is deceived:

> "*L. W. writes:* 'My blood is in bad condition. I suffer with constipation and my tongue is always coated. My skin is dark and I have pimples. I feel tired all the time, but I am too nervous to sleep. Please prescribe.'
>
> "ANSWER: Get a tube of three-grain sulpherb tablets (not sulphur) and take according to directions. They will clean your blood, aid digestion, and relieve constipation. When you get your blood pure, the other symptoms disappear."
>
> "*George asks:* 'For several months I have not been feeling well. My skin is sallow, my tongue coated, have headache, am sleepless, nervous and bothered with chronic constipation. Please help me.'
>
> "ANSWER: You need a laxative blood cleansing treatment in the form of three-grain sulpherb tablets (not sulphur). Overcome the tendency to constipation and gradually your good health and pure blood will return."
>
> "*Orrie writes:* 'I have been taking salts to purify my blood and cure my skin of itching and pimples, but don't get much benefit. Please prescribe for this.'
>
> "ANSWER: I advise three grain sulpherb tablets (not sulphur tablets), composed of sulphur, cream of tartar and vegetable extracts that remove constipation and purify the system. Take this treatment for several months for best results."

The package in which "Sulpherb Tablets" comes bears on the label one of those noninformative, alleged formulas that the shrewd "patent medicine" faker so delights in. No quantities are given, but the public is told that the tablets "contain the extracts or concentrations of Cascara, Aloes, May Apple, Nux-Vomica, Black Cherry, Capsicum, Ginger, Sarsaparilla. Also Calcium Sulphide, Sulphur and Cream of Tartar."

"Sulpherb Tablets" were examined in the A. M. A. Chemical Laboratory, and the chemists report as follows:

> "Sulpherb Tablets" are sugar coated, yellow, and weigh about 7.3 grains each, coating and all. The package states that they are three grain tablets; this probably refers to the medicament only. A qualitative examination shows the presence of emodin-bearing drugs, the taste suggesting aloes. Sulphur, calcium, sulphid, traces of alkaloid, potassium, and tartrate are present. The chemical examination shows that "Sulpherb Tablets" are probably compounded from calcium sulphid, sulphur, cream of tartar, and vegetable extractives. Of the vegetable extractives claimed to be present, aloes was indicated and a trace of some alkaloid, the amount of which was too small to permit its identification. If this alkaloid is strychnin, the quantity is insignificant, certainly not more than 1/1000 of a grain to each tablet.

Here we have, then, a simple laxative tablet, consisting essentially of drugs that have been known and used for generations, both by the medical profession and by the public. It is advertised in a way that is doubly deceitful. First the public is deceived by being led to infer that "Sulpherb Tablets" are extraordinarily efficacious; then it is further deceived by the fakish "health column" and the concealment of the "patent medicine" character of the nostrums that are recommended. Newspapers that accept such advertisements commit more than an offense against the public health; they are, for a consideration, guilty of imposing on the public's confidence by leading their readers to suppose that the "Health Talk" or "Doctor's Advice" is a department of the paper, presenting unbiased information on health subjects. The whole "prescription fake" scheme is a disgraceful combination of nostrum exploitation, quackery and low-grade advertising.

Correspondence

ALKALIS IN THE TREATMENT OF INFLUENZA

To the Editor:—It is universally agreed that in perverted metabolism by bacterial invasion, it is the acidosis that is fatal.

When the system is saturated with alkalis, there is poor soil for bacterial growth. The baneful acids may be neutralized by harmless alkalis, and these seem to act almost specifically. I have uniformly employed, and always with good results, potassium citrate and sodium bicarbonate saturation by mouth, bowel and skin.

For the past three weeks, in the present influenza epidemic, I have seen an average of 100 private patients daily. There have been all degrees of frequency and severity, and in some houses as many as six patients.

As is well known in this epidemic, there has been a very high mortality in cases occurring in pregnant women. I have seen three instances of bronchopneumonia, or "lung patches," in pregnant women, two at term, with complete recovery.

Incidentally, I have made the use of the bed-pan imperative, and have absolutely refrained from administering any of the coal-tar series.

I explain to the afflicted persons that they must be patient, and that the fever, aches and pains are inevitable for a few days, and that they must be willing to forego the seductive relief afforded by acetylsalicylic acid (aspirin), acetanilid and other heart depressants. I employ cold applications and the ordinary stimulation by strychnin, aromatic spirits of ammonia, digitalis, quinin, etc. I have always withheld all depressants.

My very successful experience in this epidemic with the saturation of the system with harmless alkalis cannot be dismissed as accidental or unique. It seems to represent an important new medical fact, or one apparently forgotten or generally overlooked. It is so simple and without any possible objection that I urge its immediate trial empirically. Further investigation in laboratory and clinic may follow later.

THOMAS C. ELY, M.D., Philadelphia.

PRECAUTIONS ON THE PART OF PHYSICIANS TO AVOID INFLUENZA INFECTION

To the Editor:—I believe THE JOURNAL would do service by suggesting precaution that should be practiced by physicians and others in the sick room with influenza patients.

Large numbers of Pennsylvania's physicians are sickening, I am sure, because they are indifferent to danger and careless about protecting themselves from the spray of moisture from the mouth of the patient.

I am getting stories every day by the score of physicians examining the chests of influenza patients in the old careless fashion, leaning over the bed with the patient talking constantly and with no attempt to have the patient cover the cough or sneeze with a towel or handkerchief. The sick rate among physicians and the death rate are appalling, and I believe physicians are needlessly sacrificing themselves because of their failure to fully appreciate what they ought to do.

I have not had time to prepare an article and have only had time to glance over the series of splendid articles illustrated in THE JOURNAL.

Masks if properly used do offer a certain degree of protection apparently and yet the every-day precaution that we practice in handling the tuberculous should be practiced at all times by careful physicians.

B. FRANKLIN ROYER, M.D., Harrisburg, Pa.
Acting Commissioner, Department of Health, Pennsylvania.

TOMATO LEAVES AND DERMATITIS

To the Editor:—I notice in an article on "Dermatitis Lycopersicum Esculentum (Tomato Plant)" by Dr. E. S. Lain (The Journal, Oct. 5, 1918, p. 1114) that after a brief search he was unable to find the tomato plant mentioned as a cause of skin eruption. In Norman Walker's "Introduction to Dermatology," Edition 6, p. 109, it says, "The following are some plants and woods which have been proved to cause dermatitis . . . tomato leaves (*Lycopersicum esculatum*)."

Malcolm MacKay, M.D., Sherbrooke, Quebec.

THE V. M. S. C. AND THE SELECTIVE SERVICE

To the Editor:—Desiring information for my own guidance in making selection of physicians for appointment as examiners on Local Boards and Medical Advisory Boards, I made inquiry of the Provost Marshal-General's Office in reference to the use, if any, he had directed should be made of the Volunteer Medical Service Corps. His reply may be useful to medical aides and others, and I send it to you for publication with the sanction of General Crowder.

John M. Dodson, M.D., Chicago.

General Crowder's letter says in part:

> . . . the Provost Marshal-General has had no thought of employing the Volunteer Medical Service Corps, as an organization, for any purpose, nor has any need for its aid arisen. On the other hand, many of its members have doubtless been utilized, individually, in the physical examination of drafted men. The medical profession has given most earnest and whole-hearted support to the work of the Selective Service, and no unofficial intermediary is required between its members and the Provost Marshal-General.
>
> F. H. Crowder, Provost Marshal-General.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VENTILATION ABOARD SHIP

To the Editor:—Will you kindly inform me how many cubic feet of air an hour a man on board ship should have?

F. D. German, M.D., Franklin, Mich.

Answer.—Where possible an adult should have an air supply of 3,000 cubic feet an hour, never less than 2,000. However, there are many factors affecting this point. When the air in a given space is changed oftener than three or four times an hour, the minimal air supply would be 3,000 divided by 4, or 750 cubic feet per man per hour. The subject is fully discussed in Pryor: Naval Hygiene, Philadelphia, P. Blakiston's Son & Co., price $3. Several chapters are devoted to the problems of air and ventilation aboard ship.

Paper Famine.—There was a paper famine in Europe in the seventh century. In A. D. 640 the Saracens conquered Egypt, and at the same time, by the Order of Omar, their caliph, the renowned library at Alexandria, consisting of 400,000 volumes, was burnt. The paper supply of the then world was derived from the papyrus bark, a reed which grew only in Egypt. Consequently, when the Saracens gained possession of the country the paper supply was cut off. This led to the adoption of a curious expedient. The writing on used papyrus paper was erased and the paper, which was thus made available, again brought into use. An old author has suggested that probably owing to this, many valuable contributions from classic writers, Tacitus, Livy and others, were lost to the world. But in this ancient expedient we have a hint for the present. There must be *thousands* of households lumbered with books of no value and many libraries with volumes occupying shelf space uselessly. In every household and every library these books should be "combed out," and the paper sent back to the mills. Paper is wanted; such books are not.—*Med. Press and Circular.*

Arkansas Eclectic May Examination

Dr. C. E. Laws, secretary of the Arkansas Eclectic Medical Board, reports the written examination held at Fort Smith, May 13-15, 1918. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Twenty-seven candidates were examined, all of whom passed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
California Eclectic Medical College	(1915)	88.1
American Medical College	(1896)	85.9
Kansas City College of Med. and Surg.	(1918)	81.4, 81.7, 82.6, 83.4, 84.3, 84.7, 84.7, 85, 85.1, 85.5, 86.2, 86.5, 86.7, 86.7, 87.5, 87.8, 88.1, 88.8, 89.1, 89.3, 89.6, 89.7, 90.3.
Lincoln Medical College	(1918)	87, 87.8

One candidate, a graduate of the American Medical College in 1906, received a license that had been revoked for one year.

New Mexico July Report

Dr. W. E. Kaser, secretary of the New Mexico Board of Health and Medical Examiners, reports that 8 candidates were licensed on credentials and 1 candidate was licensed through reciprocity at the meeting held at Sante Fé, July 8-9, 1918. The following colleges were represented:

College LICENSED ON CREDENTIALS	Year Grad.	No. Licensed
Rush Medical College	(1882) (1916)	2
Louisville Medical College	(1896)	1
Tulane University	(1911)	1
Starling Medical College	(1888)	1
Pulte Medical College	(1892)	1
Medical College of the State of South Carolina	(1904)	1
University of Texas	(1896)	1

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas	(1910)	Arkansas

West Virginia Reciprocity Report

Dr. S. L. Jepson, health commissioner of the West Virginia Public Health Council, reports that 16 candidates were licensed through reciprocity including up to July 9, 1918. The following colleges were represented:

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
American Medical Missionary College	(1902)	Tennessee
Kentucky School of Medicine of Louisville	(1903)	Kentucky
University of Louisville	(1890)	Kentucky
Tulane University	(1914)	Louisiana
University of Maryland	(1908) (1915)	Maryland
Marion-Sims College of Medicine	(1897)	Missouri
Eclectic Medical College	(1905)	Illinois
Jefferson Medical College	(1914)	Penna.
Medical College of Virginia	(1898) (1906) (1909) (1910,2)	Virginia
University College of Medicine	(1908)	Virginia
Queen's University	(1908)	Indiana

Book Notices

The Diagnosis and Treatment of Venereal Diseases in General Practice. By L. W. Harrison, D.S.O., Lecturer on Venereal Diseases and Officer in Charge, Military Hospital, Rochester Row. Cloth. Price, $7.50. Pp. 482, with 100 illustrations. New York: Oxford University Press, 1918.

Harrison has had in view a book that will bring home to the general practitioner his responsibility in the care of venereal diseases, will interest him in them, and will show him how relatively simple and satisfactory their treatment is, once the knowledge of how to treat them has been mastered. To this end he has omitted the highly technical procedures that only the expert can carry out well, and has given full space to the simpler measures, which are all that are required in the great majority of cases. This is a difficult task and requires judgment as well as a knowledge of the subject based on large experience. Fortunately the author has had this experience in civil and military practice, and brings to the subject a maturity of judgment that has enabled him to select the essential parts. The result is a book which the expert may well consult, but which is particularly useful to the general practitioner. In it he finds the well-tried methods clearly described, the important things stressed, so that he is not left in uncertainty as to what course he should follow by a multiplicity of detail which leaves him finally in confusion. It is an excellent book. Its publication is timely, and its circulation will be beneficial to the medical profession and to the public, who have a right to expect from their medical advisers intelligent care of these diseases.

A Laboratory Manual of Elementary Qualitative Chemical Analysis for Students of Medicine, Dentistry, Pharmacy and Science. By A. R. Bliss, Jr., A.M., Phm.D., M.D., Professor of Pharmacology, School of Medicine, Emory University. Second edition. Cloth. Price, $2.25 net. Pp. 194. Philadelphia: W. B. Saunders Company, 1918.

What was written about the first edition of this book applies with almost equal force to this edition. It is true that some of the glaring errors pointed out in our previous review have been corrected, and an attempt, at least, has been made to have the book conform more to the modern theories as applied to chemical analysis. There is, however, nothing new or unique either in the subject-matter or in the arrangement. There are in existence many textbooks dealing with this subject, and why there should be added this one we fail to see, unless it be as we said before simply to attach one's name to a collection of well known facts presented under the camouflage of a nice appearing book.

Aids to Rational Therapeutics with U. S. A. Pharmacopeia Equivalents. By Ralph Winnington Leftwich, M.D., C.M., M.R.C.S. Cloth. Price, $1.50. Pp. 233. New York: William Wood & Co., 1918.

The author has placed all diseases in forty groups on the basis of their pathology and similarity of treatment, believing that this is the simplest way to teach therapeutics. This conception has some commendable features. The book will not, however, be of much value to American physicians because the prescriptions are long and complicated, many of the ingredients are drugs that are not even slightly used in this country, and many of the preparations recommended will not bear the scrutiny of scientific investigation.

Emergencies of a General Practice. By Nathan Clark Morse, A.B., M.D., F.A.C.S., Surgeon to Emergency Hospital, Eldora, Iowa. Cloth. Price, $4.50. Pp. 449, with 251 illustrations. St. Louis: C. V. Mosby Company, 1918.

The author has discussed briefly all the emergency methods of a general practice. Many subjects are, of course, only enumerated. It seems a mistake to attempt to cover a field that includes the reduction and maintenance of fractures, the treatment of compound fractures, amputations, obstetric emergencies and infected wounds in so brief a way as is necessary in a volume no larger than this. The explanations are explicit and the illustrations well selected.

Medicolegal

Damages Recoverable for Miscarriage

(Wallace v. Portland Railway, Light and Power Company (Ore.), 170 Pac. R. 283)

The Supreme Court of Oregon reverses a judgment obtained by the plaintiff for damages for a miscarraige alleged to have been caused by the defendant's negligence in suddenly starting a street car from which the plaintiff was alighting, in which she claimed damages not only for the injuries and pain she suffered, but also for the loss of her child. The court says that there can be no question that a plaintiff, a pregnant woman, may recover for the pain and injury, both physical and mental, experienced by her from a miscarriage brought about by the negligent act of a defendant. She is entitled to have nature in such cases work out its proper function in due time. Any disturbance of the period or process of gestation resulting in her injury is actionable. It is only, however, for the injury to her that she can recover. She has no action for the loss of the child. The injury, if any, is too remote and speculative to form a basis for damages. Furthermore, the court holds that the defendant was not helped by an assignment of error in a refusal of the trial court to allow a witness called for the defendant to answer whether or not she was told by the plaintiff and her husband, prior to the occurrence of the accident, that they were contemplating an operation on the plaintiff. It was true that if the defendant could have shown that the plaintiff and her husband brought about the miscarriage in question by some act of their own, it would have been material to the defense; but the mere expression of an intention to have an operation performed was of no moment whatever, unless followed by testimony tending to show that the intent was carried into execution. The trial judge was clearly right in excluding the proffered testimony, as it did not appear by the record that there was any effort to supplement the offer by proof of any overt act of the plaintiff or her husband committed with a view to produce an abortion.

Cost of Operation Added to Alimony

(Rotge v. Rotge (Colo.), 171 Pac. R. 360)

The Supreme Court of Colorado affirms a judgment in favor of the plaintiff, who asked that the defendant be required to pay the necessary expenses—hospital bill and surgeon's fee—incurred for an operation which it had become necessary for her to undergo while a suit for divorce was pending between them and after she had been awarded $125 a month temporary alimony. The court says it was conceded that the surgeon who performed the operation had sued the parties to this suit before a justice of the peace and recovered judgment against both for the amount of his fee, but nothing had been recovered on the judgment, though the defendant had been garnisheed as being indebted to the plaintiff, and had answered thereto, admitting his indebtedness for the monthly alimony due. The court thereupon found the issues in favor of the plaintiff, and that the expenses of the operation and hospital bill were an unforeseen contingency, for which no provision had been made by the court and that the bills were just, and ordered that the defendant pay the hospital bill and the judgment for the surgeon's bill rendered in the justice court, and that the payment of these amounts should in no wise be deducted from or in any way affect the temporary alimony required by prior order of the court to be paid by the defendant to the plaintiff each month. Continuing, the supreme court says that the ordinary rule that, when in a divorce suit temporary alimony has been awarded the wife and the husband duly pays it, he will not be liable thereafter for necessaries subsequently furnished her, had no application to the facts of this case. It might be that the husband, in this case, might have avoided the judgment against himself in the justice court by making the defense here suggested. This he did not do, and the finding was that a judgment was rendered therein against both of the parties hereto and stood unpaid. While it was the debt of the husband, it was likewise the debt of the wife, and the substantial effect of the order was that the husband furnish her with money to pay her debt. If compliance with the order incidentally satisfied a judgment against the husband, it in no wise affected this controversy. The question here related to the power of the district court, in which the divorce suit was pending, to increase the payments required to be made by the husband during the pendency of the suit, to meet the needs of the wife which had arisen because of changed conditions, and had nothing to do with the rights of third parties as against the husband. But the order directing the defendant to pay the hospital bill incurred by the plaintiff, and the judgment in favor of the surgeon for his services, is modified to require him to pay the necessary amount into the court to be used by the plaintiff in the discharge of such indebtedness, instead of requiring him to pay it directly to persons not parties to the suit.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Thirty-First Annual Meeting, held at Detroit, Sept. 16-18, 1918

(Concluded from page 1340)

Sarcoma of the Left Ovary in a Child Twenty-Three Months Old

Dr. Herman E. Hayd, Buffalo: A small round cell sarcoma of the right ovary, about the size of a goose egg, was removed from a baby aged 23 months. The child's temperature was 101 F. It was peevish and irritable, and lost considerable flesh, had been sick about ten days, was cutting the eye teeth, and had some bronchitic sounds in the chest, with areas of bronchopneumonia in both lungs. The liver dulness was much increased. The bowels and kidneys were functionating satisfactorily. In the lower right abdominal quadrant could be felt a large, movable, smooth tumor, not painful to the touch. We treated the symptoms, irrespective of the abdominal condition. In the course of four or five days the temperature became normal, the child began to play, took considerable semisolid food, the tongue cleared up, the feverish condition of the mouth and lips passed away, and the mother was told to take the child into the country and to return in a few weeks or earlier, if the child's condition did not continue to improve. The child remained at home for ten or twelve days, when I saw it again. The lungs were clear, but the abdomen contained considerable fluid, and the mass, which was still movable, was tender. The temperature was 100 F.; the child looked sick and was again fretful and irritable. She was prepared for operation immediately. The tumor was free in the abdomen, with the right tube attached to it. The appendix was long and curled on itself, and it was also removed. The uterus and the left tube and ovary were normal. Quite a little bloody fluid ran away when the abdomen was opened. The liver was palpated and found to be much enlarged and filled with nodular masses. The child suffered little shock and recovered from the operation, leaving the hospital on the thirteenth day. It died at the end of the fifth week, no doubt from exhaustion with acute hepatitis and, perhaps, general sarcomatosis.

DISCUSSION

Dr. Thomas B. Noble, Indianapolis: My experience with sarcoma of the ovary comprises four cases in children, three of whom are dead. One, a girl of 16 who was operated on four years ago, is living.

Do Not Sterilize Women when Operating for Tuberculous Peritonitis

Dr. J. Henry Carstens, Detroit: Thousands of tuberculous nodules are left in the abdomen which are absorbed and disappear; hence we have a right to believe that the few nodules that are on the tubes and ovaries will also disappear after we open the abdomen with or without irrigation or drainage. There is no use in removing the tubes if they are only affected by tubercles. Many of the women are young and unmarried, and should not be sterilized needlessly.

Intestinal Actinomycosis

Dr. John W. Keefe, Providence, R. I.: Actinomycosis of the digestive tract practically never occurs in the stomach or small intestine, possibly because the acid contents of the stomach and the fluid secretions found in the small intestine are less irritating to its mucous lining. An acute or chronic inflammation of the appendix may open the door for the entrance of the actinomycotic organism. Actinomycosis is practically never carried by the lymphatics and but rarely by the blood stream. The method of extension is by continuity of tissue. Hence, general actinomycosis, unlike tuberculosis and blastomycosis, is extremely rare.

The early diagnosis of actinomycosis is generally overlooked. A firm swelling, painless on pressure, occupying either the right or left inguinal regions, usually the right, is the sign most frequently found in cases of intestinal actinomycosis.

The surgical measures to combat the disease consist of excision in some cases and incision in others, and curetting of diseased tissues together with the use of antiseptics and the maintenance of free drainage. Injections of 4 per cent. aqueous solution of liquor formaldehydi have been employed with success. Vaccines and serums have been found of value only in a few reported cases. The roentgen ray has not shown any marked beneficial effect. In a few instances radium has been given with marked immediate results. Large doses of potassium iodid, 90 grains, three times a day, have been given with success in many cases. The marked efficacy claimed for this drug is readily explained by the fact that it promotes the absorption of granulation tissue, acting in very much the same manner as in the case of granulomas of tertiary syphilis.

The Rôle of Congenital Colonic Membranes as a Causative Factor in Disease

Dr. J. P. Runyan, Little Rock, Ark.: Colectomy is a radical operation for the relief of intestinal stasis, and in the skilled hands of Lane may be fairly safe; but it has always appeared to me to be unjustifiable, provided a simpler and a safer operation could be devised. Acting on the hypothesis that intestinal stasis is due to colonic membrane formation, the result of imperfect embryologic development, which membrane causes more or less angulation of the bowel, we began dividing or removing this membrane with most gratifying results. It is a splendid, safe and sane substitute for colectomy in the treatment of intestinal stasis, and an operation devoid of mortality.

DISCUSSION

Dr. William Seaman Bainbridge, New York: Constipation is a symptom just as diarrhea is a symptom. The worst cases of stasis are those in which the condition is accompanied frequently with diarrhea. The frequency of the number of stools does not mean that the putrefying and noxious material is not there. The retained stool is being absorbed. There is an overflow of retention in the bowel just as there is overflow of retention in the bladder. That point Mr. Lane has emphasized repeatedly, and the worst cases of stasis are of that type. When the intestinal canal is dammed, the body as a whole or in part cannot take care of the added amount of poisoning which such retention involves. As to treatment, to say that Mr. Lane or any of those that follow him advocate colectomy for stasis is so radical that it does harm. Lane put himself on record in regard to that in 1901 when he said that nine tenths of the patients with stasis ought never to see a surgeon.

Dr. James E. Davis, Detroit: The body in its development usually follows the law that function determines anatomic form. With some arrest in the embryonic development, no interference with normal function occurs; but there are cases in which the arrested anatomic form does interfere definitely. I performed a necropsy on a child that illustrates this point. A child, aged 6 weeks, died apparently of symptoms of inanition. The right lobe of the liver appeared displaced well down into the pelvis; in fact, it seemed to be a development and a displacement. The gallbladder was in a right angled position with the midaxis of the bowel. The lower border of the right lobe of the liver was down in the lowermost part of the pelvis. Through the right hernial ring the cecum and appendix were herniated. The symptomatology was something like this: For the first four days after birth there was no trouble whatever; then there appeared a train of gastro-intestinal disturbances, and a little later metabolic disturbances were found. The terminal picture was that of ordinary inanition. In my judgment this abnormality of position was the etiologic factor of the gastro-intestinal and metabolic disturbances.

Dr. Gordon K. Dickinson, Jersey City, N. J.: In the June, 1918, issue of the *Annals of Surgery* is published a very interesting article on the anatomy and embryology of the subject under discussion. I have forgotten the name of the author. His observations are based on embryologic researches, the literature and otherwise. He says that all these bands are of embryonal origin and can be traced back to the very early period of fetal life.

Dr. Hugo O. Pantzer, Indianapolis: We find these conditions often associated with a narrow costal angle with visceroptosis, congenital defects, and so on. By percussion one can tell whether the cecum is over the brim or not. By auscultation and percussion much can be learned about the abdominal contents.

25. **Germicidal Activity of Antiseptics.**—With a view to reducing the margin of error in estimating the bacterial contents of a wound with microbe charts Perkins and his associates have been culturing the wounds, counting the number of colonies and plotting curves as in microbe charts. In order to reduce so far as possible the element of the personal equation, the work has been done by one man. The inoculations were made from the same part of the surface of the wound, one definite spot being selected and used throughout; the attempt was made to get a uniform-sized drop; the same platinum wire loop was used each time. The drop obtained was inoculated at the bedside in 2 c.c. of plain bouillon, the bouillon suspension, undiluted, was immediately poured over an agar-agar plate, which was then covered and turned upside down and marked with the patient's number, the number of the culture, and the time the culture was taken. The plate was then taken to the laboratory and placed in an incubator and kept at 37 C. At the end of twenty-four hours the colonies were counted, macroscopically, and recorded. Carrying out this procedure during different stages of wound treatment with antiseptics some idea can be obtained of the comparative strength of antiseptics and the length of time during which they are active when applied to human tissues in the presence of infection.

34. **Diverticula of Bladder.**—During a period of ten years forty-four patients were operated on in the Mayo Clinic for bladder diverticula. Judd says that diverticulum of the bladder is much more common than has been realized. The condition is perfectly amenable to surgical treatment. In this series of forty-four patients, so far as is known, all but ten are living. Two of the patients died within a few days after a drainage operation; both of these men had septic kidneys and drainage was of no avail. The other deaths occurred after the patients had been up and around for some time, and in most instances after they had gone home. The

general and functional results in the remaining thirty-four patients have been uniformly good. The functional result, in so far as emptying the bladder is concerned, may, Judd says, be slow to adjust itself, though eventually it will be practically perfect.

38. **Receiving and Operating Pavilions for Modern Base Hospital.**—Ashhurst describes the adaptation of standard barrack buildings to the uses of receiving, bathing, operating, and roentgen-ray pavilions in a base hospital. The buildings described form part of Base Hospital 34, American Expeditionary Forces, which is situated in the outskirts of a large city, at a considerable distance from the front.

40. **Action of Pituitary Extract on Kidney.**--Knowlton and Silverman found that the oxygen consumption by the kidney is not increased during the diuresis induced by pituitary extracts. Using the oxygen consumption as the criterion, there is no evidence that pituitary extract stimulates the renal cells. Throughout their experiments increased blood flow through the kidney was an invariable accompaniment of pituitary diuresis. From the evidence at hand it seems possible to explain the diuretic action of pituitary extract entirely on the basis of the vascular changes and increased filtration pressure obtaining in the kidney.

41. **Effect of Food in Increasing Oxidation.**—The increase in oxidation following the ingestion of food is attributed by Burge and Neill to the increase in catalase produced by the stimulation of the digestive glands, particularly the liver, to an increased output of this enzyme. The glycerin radical of the fat molecule is responsible for the stimulating effect of the fats; the end products of protein digestion, presumably the amino-acids, for the stimulating effect of meat; and the simple sugars for the stimulating effect of the starchy foods.

42. **Material Lost in Menstruation of Healthy Women.**—In the experiments referred to the subjects were healthy women who were working in the laboratory from ten to twelve hours a day. In general the object was to ascertain whether the calcium and phosphorus requirements of women differed materially from those of men. The diet of each subject was uniform from day to day and the daily intake and output for nitrogen, calcium and phosphorus were determined by analysis. The data obtained show that there is no pronounced periodicity in the output of phosphorus and calcium and that the amounts of these elements lost in menstruation are not sufficient to make the nutritive requirements of women for these elements materially different from those of men of the same weight.

47. **Extracts of Several Parts of Ox Pituitary.**—According to Atwell and Marinus a pars tuberalis may be distinguished in the bovine hypophysis. It differs histologically from both the pars intermedia and the pars anterior propria. But, extracts of the pars tuberalis are very inferior to extracts of the pars intermedia in producing contractions of the isolated uterine segment and are likewise inferior to extracts of the neural stalk in raising the blood pressure of the dog. Extracts of the pars tuberalis equivalent to 5 mg. of fresh gland substance failed to produce a rise of blood pressure in the rabbit. It is believed that the active effects displayed by extracts of the pars tuberalis are due to an inclusion of some of the neural stalk substance during the preparation of the extract. It would seem improbable that the pars tuberalis is responsible for the origin of active principles which increase uterine contraction or raise the blood pressure. An extract of the pure pars intermedia of the ox is capable of producing a strong pressor effect when injected intravenously into the dog. An extract of pure pars intermedia representing 5 mg. of the fresh gland substance produces a distinct rise of blood pressure in the rabbit. An extract of the pure neural stalk is fairly powerful in producing a rise of blood pressure in the dog. This removes one objection to the possibility that the secretion of the pars intermedia passes into the neural lobe and then, via the neural stalk, into the third ventricle.

50. **Chemistry of Brain of Normal and Ataxic Pigeons.**—The brains of birds which have very little control of the voluntary movements (ataxia?) were analyzed by Koch and Riddle. The data thus obtained are compared with similar data obtained on the brains of normal birds of the same parentage. The derangement first appeared (mutation?) under conditions known to lead to weakness in the offspring. The disorder is exhibited in all degrees and has been inherited undiminished to the fifth generation. Usually it is shown from the earliest age of the bird and is probably present throughout the whole development of the bird. The brains of the affected birds show increased values for moisture, protein and extractive sulphur; decreased values for lipoids, phosphatids and cholesterol. In general the less ataxic individuals show values intermediate to those of the normals and most ataxic. The distribution of sulphur and phosphorus in the various chemical fractions was determined. The results of the analyses of the affected brains are interpreted as suggesting a chemical underdifferentiation or immaturity of these brains. The brains of affected birds of approximately mature age are chemically more like the brain at earlier stages of development.

60 Study of Eight Cases of Acute Nephritis. D. W. Atchley, New York.—p. 370.

54. **Empyema at Camp Upton.**—Eighty cases of a highly virulent type of empyema have been analyzed by Brooks and Cecil at Camp Upton in a series of 300 pneumonias. Fifteen of these were caused by the pneumococcus; fifteen others were sterile; the remainder of the cases were caused by streptococcus,. usually of the hemolytic type. In this series of cases empyema has been constantly associated with pneumonia of either the bronchial or lobar type. Usually a bronchopneumonia has accompanied a streptococcus empyema, and a lobar pneumonia the pneumococcus empyemas. In the great majority of cases the organism which has been found

to be the causative agent in the pneumonia has also been isolated in pure culture from the pleural exudate. In nine cases, however, a pneumococcus pneumonia was associated with a streptococcus empyema. The onset of the pneumonia and the empyema is apparently simultaneous in some cases. This epidemic of empyema has been, in large part, independent of measles and other similar infections.

The clinical symptoms and the physical signs differ from those of classic empyema. Diagnosis is frequently difficult by reason of the equivocal physical signs and the indefinite symptomatic picture. Diagnostic aspirations are the most certain means of discovery of the condition in its early stage. The roentgen ray stands second in diagnostic importance. Of the physical signs, alterations in percussion seem to be the most helpful. The interstitial type of bronchopneumonia, recently described by Cole and MacCallum, is usually found associated with streptococcus empyema. Fibrinopurulent pericarditis is the most frequent complication. Pyopneumothorax has also been observed in a number of cases. The mortality rate is high and the prognosis is serious. Medical treatment is essentially expectant. The most efficacious method of surgical treatment and the correct time for its application are yet to be determined.

55. **Acceleration of Heart Beat.**—A young medical student who is entirely healthy and is apparently free from all physical and neurotic defects has had no cardiovascular symptoms whatever and physical examination shows the heart to be of normal size and free from abnormal sounds and murmurs. Attacks of tachycardia have never been noticed. He discovered the ability to increase his heart rate voluntarily during the course in physiology in his freshman year and has practiced it only at times of making observations. During the period of acceleration there is a very slight increase in the rate and the depth of respiration and the pupils dilate moderately as recorded by other observers. No definite physical effort is made, but constant mental concentration must be maintained, which, after several, closely repeated trials, becomes quite fatiguing. The rate begins to increase almost immediately following the word of command and reaches its maximum after about ten heart cycles. All tracings show a decrease in amplitude of the pulse waves rather than an increase with marked dicrotism. There was a distinct rise in blood pressure with each acceleration with the exception of the effort at the height of the atropin effect, when there was a drop of 10 mm. from the reading made five minutes before. The latter reading, however, was 10 mm. higher than the first record made before the atropin was given. The greatest increase noted was one of 18 mm. accompanying an acceleration of 27 beats per minutes.

Electrocardiograms show no distinctive characteristics other than a slight notching of R and a diphasic T in the third lead. There is a definite, but not unusually marked, sinus arrhythmia. During the periods of acceleration there was no change in the P-wave, in the P-R interval, nor in the distance from the beginning of R to the end of T. The amplitude of T was not changed. There was some rhythmic variation in the height of R both before and during the period of acceleration. The general average of the R deflections was slightly lower during the periods of acceleration, but by not more than one tenth of the height preceding the increased rate. After subcutaneous injection of 0.002 gm. of atropin sulphate the rate was increased from 69 to 94 beats per minute. Electrocardiograms taken at this time show a very slight increase in the amplitude of T in the first lead and a correspondingly slight decrease in the height of R. No change in the distance from the beginning of R to the end of T could be made out. The sinus arrhythmia was almost, but not completely, obliterated. When respirations were forced without atropin the sinus arrhythmia becomes more marked.

56. **Endocarditis and War Wounds.**—Acute endocarditis was observed by Karsner in fourteen necropsies. Twelve were pure acute disease and two showed acute lesions superimposed on preceding chronic lesions. The twelve acute cases showed involvement of the aortic valve alone in five cases; the mitral, two cases; the pulmonary, one case; the tricuspid, one case; combined mitral and aortic, three cases. One case showed chronic mitral stenosis with acute mitral and aortic lesions; one case showed chronic mitral and aortic stenosis with acute mitral lesions. *Staphylococcus pyogenes-aureus* was isolated in three cases, two of which were pyemias and one was a septicemia. *Streptococcus pyogenes* was isolated in nine cases, two of which were pyemias and seven were septicemias. Two cases were clinically and pathologically septicemias, but were not demonstrated to be so bacteriologically. All the patients had suffered serious primary wounds, five of which involved joints and four others of which involved other serous cavities. These wounds are irregularly distributed in regard to the valves attacked except that both the cases showing superimposition of acute on chronic lesions were penetrating wounds of the pelvis. In contrast to these figures, there were six cases of infected wounds of the joints which failed to show endocarditis, twenty-three cases of wounds of other serous cavities not including head wounds and forty-two cases of septicemia or pyemia without noticable lesions of the endocardium.

59. **Epidemic of Mumps at Camp Wheeler.**—Among approximately 18,000 men at Camp Wheeler, there were 5,756 cases of mumps, an incidence of 32 per cent. Every third man in the division, in other words, has had mumps. Of 13,638 total admissions to the hospital to March, 1918, almost one half were mumps—42.2 per cent. The cost of the epidemic to the government was at least $1,000,000. Six hundred and eleven had testicular involvement of various kinds. Suppurative otitis media occurred in twenty cases. Pancreatitis occurred in fourteen cases. Five cases of lobar and one case of bronchopneumonia occurred. There were nine cases of bronchitis of the ordinary type and course. Radin says that the most diagnostic prodromal sign, pathognomonic, in fact, was first noted by Lieutenant Hathcock. The sign is tenderness just beyond the angle of the jaw on running the finger toward the angle, under the mandible. If the parotid gland is at all involved, the patient winces with pain. This occurs before any swelling can be made out. It is almost constant, it is early, it is definite and it is exclusive; therefore it is diagnostic.

61 *Kidney Function in One Hundred Cases of Hypertension. W. C. Rappleye, Foxborough.—p. 441.

61. **Kidney Function in Cases of Hypertension.**—A study of the blood urea nitrogen, elimination of phenolsulphonephthalein and urine analysis was made by Rappleye on 100 cases of elevated blood pressure, using the figure of 150 to 155 mm. systolic pressure as the low value for selection. With but four or five exceptions, the patients were in apparently good physical condition and active, none showed any edema, dyspnea, fever or other compromising conditions. In this group of patients 70 per cent. showed blood urea nitrogen values below 16.0 mg. per 100 c.c. (whether considering the whole group or only those showing a systolic value of over 170 mm. or a diastolic figure of over 100 mm.), and 66 per cent. showed a dye excretion of 40 per cent. or higher; 16 per cent. showed a value of 40 per cent. A slightly lower percentage was found in those patients showing a higher blood pressure (systolic of 170 mm. or over, diastolic of 100 mm. or over). Twenty-eight per cent. showed both a urea nitrogen of 16.0 mg. or over and a dye excretion of 40 per cent. or less. Ninety per cent. of the cases showing a urea nitrogen of 16.0 mg. or over had a dye excretion of 40 per cent. or less. Twenty-four of the cases showed a blood pressure over 160 mm., a urea nitrogen below 15.0 mg. and a phthalein over 50 per cent. There have been thirteen deaths in this group with eleven necropsies. The causes of death in ten of the thirteen cases were associated with either the cardiovascular system or acute infections.

65 Botulism. E. C. Dickson.—p. 85.
66 Some Aspects of Military Ophthalmology. S. H. McKee.—p. 87.

64. **Treatment of Early Stages of Trench Nephritis.**—Strathy says that with rest in bed and a simple diet of milk and milk puddings the large majority of patients improve rapidly. The symptoms calling for active treatment are cough, dyspnea, decrease in urine, headache and convulsions. At the casualty clearing station in which Strathy was stationed if a patient was markedly edematous or his blood pressure high a hot-air bath was given. In nearly all cases this produced free sweating, relieved the cough and headache, and decreased the edema. The patient's bowels were kept fairly free with Epsom salt, but the patients were not severely purged. If the dyspnea did not then subside and was severe, oxygen inhalations almost invariably gave considerable relief. After losing two patients whose deaths were both directly due to the affection of the lungs and pleurae, oxygen treatment was given to all cases of extreme dyspnea, and apparently carried several severe cases through, but when the dyspnea was not relieved by oxygen, and later, when the use of oxygen was forbidden owing to shortage of oxygen supply, aspiration of the hydrothorax was carried out, and immediate improvement resulted. One patient who was in extremis and appeared likely to die within five minutes was aspirated. After the removal of the fluid he was immediately improved and ultimately recovered. The hydrothorax did not recur. Opium in any form for the relief of cough or sleeplessness Strathy abandoned after some unhappy results from its use. It appeared to increase the patient's cyanosis. For convulsions spinal puncture and withdrawal of fluid was done in three out of four cases. The three recovered and the unpunctured patient died. Strathy believes it should be done either when an attack of convulsions is threatening, or as soon after the first convulsion as possible. One-fourth grain of morphin was always given at the onset of a convulsion.

67 *Sinus Spud. W. S. Halsted.—p. 195.
68 Medical Industrial Relations of War. D. L. Edsall, Boston—p. 197.
69 Thymus Tumor Associated with Acute Lymphatic Leukemia. R. H. Major, Rosedale, Kan.—p. 206.
70 Wit and Satire on Physician in Hebrew Literature. H. Friedenwald, Baltimore.—p. 209.

67. **Sinus Spud.**—Four cases are cited by Halsted. The nature of the tumors or spuds was the same in the four cases. In the three perineal cases the pictures, were, in every particular, so nearly identical that, presumably, they had also a cause in common. In one instance a urethral fistula developed two years after the excision of the sinus and its fibrous wall. Halsted says that from this we might naturally conclude that a urethral lesion was responsible for all of the perineal spuds, notwithstanding the fact that no one of the three patients could recall having had at any time a urethritis. But this patient had been treated for fistula-in-ano a year before his perineal tumor appeared, and another patient had been operated on for hemorrhoids. In two cases operated on by Halsted, he felt that he could assert positively that at the time of operation the sinus did not communicate with either rectum or urethra. In both of these cases, furthermore, the sinus did not extend in either direction, to the end of the spud. The original urethral or rectal openings must have been very minute and have become closed.

In the three perineal cases the situation of the spud was precisely the same, and the dissection in the two operated cases led to the same spot, namely, to neighborhood of the bulbomembranous urethra. If the three cases had been of rectal origin it is extremely unlikely that the rectal perforation would in each have been identically at the same point. Correct interpretation of the condition is important, although failure to recognize the nature of the tumor could hardly be disastrous. Faulty diagnosis, however, caused three of the patients great distress. A finger-shaped, subcutaneous tumor of the perineum, quite free at its tip and with the hardness and elasticity of cartilage, is probably a sinus spud and may be recognized almost at the first touch of the palpating finger.

81. **Antagonism Between Thymus and Parathyroid Glands.**—From the facts stated by Uhlenhuth it is evident that the thymus gland of mammals contains a substance which is capable of producing tetany when fed to the larvae of certain species of salamanders (*Ambystoma opacum* and *Ambystoma maculatum*). As long as the larvae have not developed their own thymus glands, they are able, by means of some mechanism, to counterbalance the tetanic action of the thymus substance introduced in their food. When, however, the secretion from their own thymus glands is added to the thymus material introduced with the food, this mechanism of preventing tetany becomes inadequate and tetany ensues. If the thymus is the organ by whose action tetany is produced, Uhlenhuth says, we can understand why tetany in human beings occurs far more frequently in children than in adults, since in the latter the thymus gland is replaced, at least to a great extent, by connective tissue. The relation of thymus to tetany may also possibly explain the occurrence of tetany during pregnancy; while the parathyroids of the mother may be sufficient to prevent tetany from her largely atrophied thymus, they may not be sufficient to prevent tetany from the excess of thymus substance furnished by the fetus to the blood of the mother.

82. **Tetany-Producing Substance in Thymus Gland.**—Uhlenhuth believes that the effect of the thymus gland in producing tetany is due to a specific tetany toxin produced by and contained in the thymus, hence the thymus gland must be added to the group of glands for which the function of internal secretion has been demonstrated.

85. **Mechanism of Disinfection and Hemolysis.**—Brooks presents a critical discussion of the part played by the physicochemical process or group of processes leading to death, laking, and similar effects in determining progressive changes in the number of individual cells succumbing in

successive units of time to the action of the deleterious agent. He believes that the course of such processes as hemolysis is very largely dependent on variations in resistance among the different individuals, and secondarily on the course of the fundamental reaction. The fundamental reaction may be either a simple process, or the expression of a complex series of changes whose rate is at all times governed by that of the slowest of the series.

90 *Relation of Tuberculosis to Dementia Praecox. E. E. Southard and M. M. Canavan, Boston.—p. 193.
91 Case of Spina Bifida Occulta in Third Cervical Vertebra. S. N. Clark, Chicago.—p. 201.
92 Pathology of Human and Experimental Poliomyelitis. H. S. Howe, New York.—p. 206.

90. **Relation of Tuberculosis to Dementia Praecox.**—On account of a recent revival of interest in the relation between tuberculosis and dementia praecox, a brief statistical inquiry was made by Southard and Canavan, using data of the Massachusetts necropsy series. It was shown that dementia praecox, found in 8 per cent. of 5,040 Massachusetts necropsies, was far more apt to be terminated by tuberculosis than manic depressive psychosis, occurring in 7 per cent. of the basic series. One hundred and twenty of 403 dementia praecox patients died of tuberculosis, and but forty-three of 339 manic depressive psychosis patients died of tuberculosis. Eighty-seven cases of dementia praecox showed neither death due to tuberculosis or any other anatomic feature whatever (even including adhesions in various parts of the body) which would conceivably be related with tuberculosis. Ninety-five cases of manic depressive psychosis were equally free from tuberculosis.

The question whether these nontuberculous cases of dementia praecox were actually victims of the disease and not subject to erroneous diagnosis was taken up in the statistical study from the Danvers symptom catalog from which thirty-six deaths from tubercle were taken to contrast with twenty-seven deaths without the slightest evidence of tuberculosis whatever. Some of the most characteristic symptoms of dementia praecox were found equally distributed in the two groups and strongly represented in both, so that no major doubt can be raised as to the accuracy of the diagnosis of dementia praecox in the nontuberculous group. For example, the fundamental symptoms of dementia and delusions of paranoid type are found equally represented in both. Nor was it found that the fundamental symptom dementia was more frequently shown in the fatally tuberculous cases than in the others.

Tuberculosis appears to dispose certain cases to catatonia and to hyperkinetic symptoms of a presumably psychogenic or cortical nature. Per contra, the nontuberculous cases showed more instances of the peripheral symptom, motor restlessness, than did the tuberculous cases. Another hypothesis raised by this statistical study is whether tuberculosis does not cause a trend of symptoms in dementia praecox over toward manic depressive psychosis. Does not the superposition of a somatic feature like tuberculosis on the encephalic or psychogenic picture of dementia praecox cause also a superposition of sundry features showing an alliance with those of manic depressive psychosis? Or, does not tuberculosis tend to make dementia praecox look more at times like manic depressive psychosis than dementia praecox is ordinarily likely to look?

97 *Tonus Waves in Terrapin Auricles as Affected by Pilocarpin, Atropin and Epinephrin. C. M. Gruber and C. Markel, Denver.—p. 53.

93. **Rise in Body Temperature Induced by Drugs.**—The drugs used by Hill in these experiments were the fluidextract of ergot and a saturated solution of calcium lactate. Fluidextract of ergot in doses of from 1 to 1.5 c.c. per kilogram body weight administered intravenously to rabbits induced a steady rise of body temperature from 1.5 to 2.2 C. Higher doses proved fatal. Calcium lactate in doses of from 5 to 8 c.c. of a 1:20 solution administered intravenously to rabbits caused an initial fall of from 0.4 to 0.6 C. in temperature accompanied in the higher doses by symptoms of calcium poisoning. This was succeeded by a strong rise of from 1.5 to 2.5 and disappearance of the symptoms of poisoning. Higher doses were fatal. In sublethal doses, neither fluidextract of ergot or calcium lactate caused any decisive alteration in the protein quotient or the leukocyte count. These experiments show that the aseptic fever induced by these drugs causes no alteration in the globulin content of the blood nor does any alteration of note occur in the leukocyte count.

96. **Auricular Tonus Waves as Affected by Epinephrin.**—These experiments were performed on the hearts of twenty-seven terrapin immersed in Ringer's solution. Epinephrin caused a disappearance or a diminution in the tonus waves in all hearts. In those experiments in which the strength of the solution was strong the waves ceased almost at once. In those in which a more dilute solution was employed only a few tonus waves appeared after its addition to the Ringer's solution. No oxygen was used during the first mentioned observations, whereas continuous oxygen was employed throughout the second set of experiments.

97. **Auricular Tonus Waves as Affected by Pilocarpin.**—Pilocarpin hydrochlorid was found to have a marked effect on the contractions of the heart, almost completely stopping them, but has no effect on the tonus waves. Atropin sulphate increases the general tonus of the heart when injected into the solution in which the muscle is contracting, either in the normal solution or following the administration of pilocarpin. It has only a slight effect, if any, on the tonus waves increasing them along with the general tonus. Epinephrin chlorid or epinephrin (crystalline epinephrin) cause a disappearance of the tonus waves in the atropinized heart as it does in the normal heart.

110. **Repair of Large Peripheral Nerve Gaps by Neuroplasty.**—The conclusions reached by Mackenzie from the study of three cases are: Regeneration and recovery of function is promoted by the use of nerve flaps. Both central and peripheral flaps can be used for such purposes. A peripheral flap, by laying down a nerve path, may promote regeneration over a great gap; in one case quoted regeneration occurred over a gap 10¾ inches in length. The approximation of nerves and their repair should be done in all cases with the least possible delay. (This would apply as well to cases which are infected as to clean cases.) The arrest of trophic shock can be promoted by early closure of large gaps by flaps. Unimpaired nerve tissue should always be utilized for the effective repair of damaged nerves. In their repair, nerves can be successfully sequestrated in muscular tissue so as to promote their own regeneration and that of the muscles in which they are embedded. The principle of sequestration can be utilized in proper cases so as to avoid infected zones in wounds and also scars and other obstacles to nerve repair.

118. Abstracted in The Journal, June 22, 1918, p. 1976.

120. **Foreign Body Localization.**—The method described by Busby is said to enable the operator to ascertain the depth of foreign bodies in a simple, practical manner, eliminating all mathematical problems, the reading or compilation of charts, at the same time minimizing the technic and thereby removing many possibilities of error. It is not necessary to know the distance of the tube from the patient, nor the distance from the screen to the skin, nor the distance the tube moves on a horizontal plane. Any actual measurement of these factors may be disregarded, yet the correct depth of the foreign body may be read on a scale of millimeters immediately after the operation is completed. This method is based on the fact that the two opposite sides of the parallelogram are equal in distance, one from the other, as described by Barret and Andrault.

124. **Pulmonary Edema During Pregnancy.**—The authors cite two cases of acute pulmonary edema occurring during pregnancy, one at six months and the other at eight months. In both cases the outstanding feature was a tremendously high-blood pressure. In the first case, apart from the urinary findings, there was very little else to be discovered before the onset of the acute symptoms. The second case, had a considerable amount of edema elsewhere in the body, but in the first case this edema was confined to the lungs. In neither case, so far as could be discovered, was there any preexisting cardiac lesion. These patients can hardly be said to be eclamptic because they had no convulsions, nor did they die in coma without convulsions. The condition is interpreted as being due to a profound toxemia giving rise to a high blood pressure which finds its outlet in a spot of weakened resistance in the lung. These cases show that blood pressure findings are the best indications regarding the severity of a given case of preeclamptic toxemia. Moreover, in dealing with albuminuria and high blood pressure during pregnancy one should have in mind not only the possibility of a development of convulsions but also that at any time a complication far more tragic than the ordinary eclampsia may arise.

125. **Temporary Internal Fixation of Fractures.**—The Browns endorse temporary fixation of a fracture, preferably with the Parham-Martin band, or, if not feasible, with a Lane's plate; this fixation to be removed under local anesthesia as a rule at the end of five or six weeks. In cases of compound fractures where interference is otherwise indicated for the control of hemorrhage, removal of foreign bodies, disinfection or coaptation of fragments, they have found nothing to contraindicate the use of internal fixation with the express idea of removing it as soon as there has been sufficient callus and fibrous tissue formed to hold the fragments in apposition. They are unable to see any comparison between this method, where the above procedures are otherwise found necessary, and that of transfixation by means of screws or pegs driven into bones for the purpose of making extension. The internal fixation frequently reduces or solves the problem of extension.

1. **Diagnosis of Functional and Organic Paraplegia.**—When the diagnosis has been especially difficult, or the symptoms slight and indefinite, the three indications of organic disease which Williamson has found of the greatest service have been the Babinski or Oppenheim reflex, the loss of the Achilles tendon reflex, and the loss of the vibrating sensation, while other forms of sensation are unaffected. The onset of a number of organic affections are: paresis with loss of the Achilles tendon reflex, as in early anterior poliomyelitis—chronic, subacute or acute; paresis with loss of the plantar reflex and loss of the Achilles tendon reflex (in many organic diseases); paresis with double sciatica and loss of the Achilles tendon reflexes, as in early cauda equina lesions;

paresis with loss of the Achilles tendon reflex, loss of the vibrating sensation, and pains in the legs, as in early peripheral neuritis; loss of the vibrating sensation with very slight incoordination and very slight paresis, with or without a Babinski reflex, as in early combined posterolateral degeneration of the cord; paresis, with Babinski reflex (in many organic affections); paresis with loss of the vibrating sensation and Babinski reflex (in the early stages of several organic diseases of the cord); root pains, or root symptoms, followed after a period of weeks or months by paresis, as in meningeal spinal tumor.

6. **Value of Flavine.**—Savery endorses the use of flavine in septic injuries. He points out that a few essential facts must be borne in mind for the use of flavine: 1. In the first place it is imperative that all affected parts should be reached so far as possible, and in order to carry this out thoroughly he always endeavors to introduce flavine solution by means of a hypodermic or dental syringe. 2. The flavine soaked gauze should always be applied as wet as possible and any cavities filled up with the solution immediately before, and the part covered with a piece of mackintosh and wool. 3. A third important feature is the duration of the use of flavine; if applied continuously, a yellowish pellicle will appear on the surface of the wound in the course of a few days. This pellicle appears to be composed of leukocytes and fibrin. The best results from flavine have been obtained from its early application and the appearance of the pellicle is an indication that a change should be made, for example, to eusol, brilliant green, or magnesium sulphate, on the fourth day or thereabouts, and then to revert to flavine once in every three days. This method has given great satisfaction. An enormous amount of sepsis would be prevented by the primary use of flavine, and therefore its use is advocated by Savery in every case septic or likely to become septic.

9. **Operation for Varicose Veins.**—The simpler method of excision is endorsed by Steward as being the most useful operation in these cases. Suitable incisions are made and the veins removed, the cut ends of the main veins and the larger tributaries being ligatured with fine catgut. The incisions are then closed by means of Michel's clips, the limb wrapped in large sterile pads, and a bandage applied evenly and firmly, but not too tightly, from the foot upward.

25. **Disinfection in Lice-Borne Diseases.**—Hunter describes the railway van disinfector devised by Lieut.-Col. G. F. Stammers, F. A. M. C., to meet the needs of disinfection of troops on a larger scale, and to form a part of the British Sanitary Train for Inoculation and Disinfection. The principle of action of the van disinfector is disinfection by current steam, supplied by and directly discharged in greatest volume and force into one or two ordinary railway vans (suitably adapted) by the railway engine, which conveys them along the line to the place most conveniently adjacent to the troops. The cost of adaptation is only $150 to $200, the working of it simple and easy. Each double van is capable, if fully employed, of carrying out disinfections at the rate of 500 kits with 1,000 blankets and 500 overcoats every two hours; of 2,000 kits with 4,000 blankets and 2,000 overcoats in a day of eight hours; of disinfecting over 10,000 kits with 20,000 blankets and 10,000 overcoats in four days; and 18,000 kits with 36,000 blankets and 18,000 overcoats in nine days.

With one disinfector alone Hunter has disinfected the kits and blankets of a hospital with 1,000 beds in four hours; the kits, blankets, and camp bedding of 4,000 prisoners of war in sixteen hours; of 1,500 camel corps men in about twelve hours. Divisions of troops can be dealt with at the following rate: 8,000 men in four days, 15,000 in twelve days (3,800 of these being done in one day); of 16,000 in twelve days; 10,000 in four days, and 18,000 in ten days. As regards ordnance clothing, this can be disinfected, in sackfuls at a time, at the rate of many thousands of articles every two hours, tens of thousands daily, and hundreds of thousands weekly.

A most striking illustration of the advantages of this rapidity was afforded in one instance, where a van disinfector which had just disinfected a division of 18,000 troops in twelve days in one area went off about 500 miles to a center in southern Europe, where some cases of typhus had occurred among the native laborers. It disinfected the whole of the troops and laborers (1,500 in number) in three days, and was back at work again in its former area disinfecting another division on the fourth day.

In the first three months of their work two van disinfectors carried out the disinfection of 170,000 kits, 170,000 overcoats, 340,000 blankets and great masses of ordnance clothing. Since that time the disinfectors in use have been the most prominent and effective measure of preventive work in Egypt, each double van disinfector being capable of carrying out in the simplest and most efficient way in all parts of the war area—up to railhead—disinfection of troops and native laborers to the number of 60,000 men monthly. The total number of disinfections carried out in twelve months (May, 1916, to April, 1917) among a monthly average of 40,000 laborers was 495,000—an average of over 40,000 a month.

26. **Use of Scapula in Thoracoplasty.**—The bone of the scapular body is utilized by Adams to take the place of resected ribs, and its muscles to secure mobilization of the lung and raising of the diaphragm, both essential factors in the healing of these cases.

27. **Treatment of Septic Gunshot Wounds of Knee Joint.**—In the earliest stage of infective traumatic arthritis, Neve says, an attempt should be made by tapping and distending the joint with some antiseptic, such as flavine or iodoform emulsion, to abort the sepsis. This is being successfully done in France. Good fixation of the limb is essential. When sepsis is established thorough drainage is essential; anterior lateral incisions do not suffice; the Peck method is not successful. Suprapatellar, anterolateral, and posterolateral incisions should be used in combination. If there is bone damage excision is desirable in most cases, and the bone surfaces may be kept apart.

Carrel's method offers the only effective way of introducing an antiseptic fluid into the recesses of the injured joint.

With other methods burrowing pus very frequently occurs, with abscesses tracking up and down the limb and septic absorption; and amputation is apt to be performed too late, when the vital powers have succumbed to the prolonged strain and sepsis has become generalized with a perhaps fatal result.

43. **Surgical Treatment of Intussusception.**—Three hundred and seventy-four cases of intussusception treated by laparotomy at St. Thomas' Hospital during the twenty years from 1898 to 1917, inclusive, are analyzed by Romanis. The total mortality was 121, or 32.3 per cent.; but since 1898 the mortality percentage has been lowered from 48.1 per cent. for the four year period, 1898 to 1902, to 19.2 per cent. for the period 1913 to 1917. There has been a more or less continuous increase in the number of patients operated on, but a steady drop in the mortality; the lowest annual mortality of the series recorded in any year being in 1915, when twenty patients were operated on, with a mortality of 10 per cent. This lowering of the death rate is due to the fact that patients have on the average come to operation earlier; many minor alterations in the technic of abdominal surgery have been, and are still being introduced from time to time.

With regard to intussusception operations in particular, it is only during the last ten years or so that surgeons have come fully to recognize the importance of the time-factor in the case of abdominal sections performed on infants and tiny children, and to realize that every minute saved during the operation of opening the abdomen of a small child increases the chances of its recovery. The harmful effects of general anesthesia in infants has been taken into account, and every effort made either to reduce its duration to a minimum in various ways or better, to substitute spinal anesthesia in its place. It is, therefore, to these three factors, Romanis says, that we must look as offering the most probable explanation of the decided improvement in the results of surgical treatment in these cases, rather than to any supposed diminution in the time that elapses before operation is undertaken.

The different operations performed in this series were as follows: (1) laparotomy and reduction in 301 cases with mortality 26 per cent.; (2) laparotomy, reduction and appendicectomy in thirty cases with mortality 40 per cent.; (3) laparotomy, resection and union in thirty cases with mortality 63.3 per cent.; (4) laparotomy, resection and artificial anus in ten cases with mortality 100 per cent.; (5) laparotomy and lateral anastomosis above and below the tumor in three cases with mortality 33.3 per cent. This bears out the well known fact that if anything more than the simple procedure of opening the abdomen and reducing the invagination is required, the mortality rises by leaps and bounds; but it also shows that irreducible or gangrenous intussusceptions that require anything more severe than simple reduction are, fortunately, comparatively rare, only forty cases of the above series failing to be reduced. In other words, 89.2 per cent. of all cases can be reduced on opening the abdomen.

The important question whether an intussusception will be reducible or not depends almost entirely on the interval that has elapsed between the onset of symptoms and the performance of laparotomy. Of the above cases, in only one case in which operation was performed within twenty-four hours of the onset of symptoms was a resection necessary; of the cases dealt with between twenty-four and twenty-six hours after onset, only two required resection, and of those in which the interval was between thirty-six and forty-eight hours four were irreducible. All the other patients in whom an enterectomy was found necessary had been ill for over forty-eight hours before operation was performed. In dealing, therefore, with an intussusception in which symptoms have been present for less than thirty-six hours, one can feel fairly confident that reduction will be possible.

45. **Treatment of Hemophilia with Emetin.**—Monro records the remarkable result of using emetin in checking the bleeding on one occasion in a case cited. Monro gave one-half grain of emetin hydrochlorid by hypodermic injection in the forearm. The next morning the patient was in a profuse perspiration; he complained of pains in his joints, and his arm was swollen. The urine was scanty and still bloody; the temperature had fallen to 100. The day following his temperature was normal, the joints were better, and he passed normally colored urine—the first for exactly ten weeks. From that time on the patient made a steady recovery.

50 *Aviator's Heart. G. Etienne and Lamy.—p. 151.
51 Influenza in Switzerland. J. Renault.—p. 153.

48. **Projectile in Left Ventricle.**—Le Fort demonstrated before the Académie the first case in France in which a scrap of shell (8 by 4 by 4 mm.) was successfully removed from the cavity of the left ventricle. He has previously reported the successful extraction of a projectile from the cavity of the left auricle. This makes the eleventh projectile he has extracted from the heart in a total of nine cases. One of the men succumbed the fourth day thereafter but all the others recovered.

50. **Aviator's Heart.**—Etienne and Lamy report that in the large numbers of aviators they have examined, the left ventricle was found constantly hypertrophied. This hypertrophy was more marked among the aviators doing bombing, etc., that require high flights. It was always moderate and well tolerated, and occurred indiscriminately in those who had or had not been trained in athletics before.

58 Local Eosinophilia in Dermatitis. Maccia and Petzetakis.—p. 594.

54. **Intensive Treatment of General Paresis.**—Sicard and Roger have been treating general paresis with intravenous injections of an arsphenamin preparation in large doses. In their twelve cases there never was any aggravation of the physical or mental condition. When intoxication from the medication was impending, this was revealed by blistering when the skin was painted with tincture of iodin. Another sign revealing intoxication before it became otherwise apparent was the abolition of the Achilles tendon reflex. This occurred in five of the cases during the second or third month of the intravenous treatment, to a total of 12 or 16 gm. of the drug. There was evidently incipient arsenic neuritis.

55. **Walled-Off Meningitis.**—In the three cases reported, the meningococci disappeared from the spinal fluid although the meningitic symptoms persisted. Then suddenly, after an interval of three or six days, they appeared anew in the lumbar puncture fluid. They did not disappear definitely until after fourteen intraspinal and one intraventricular injection of the serum.

61 Early Vaccination of Infants. R. Wurtz.—p. 294.
62 Extraventricular Hydrocephalus. A. B. Marfan.—p. 297.

59. **Protection of Young Infants.**—Marfan reviews the history of the movements for protection of young infants from ancient Rome to modern times. In conclusion he urges the establishment in crowded parts of the city of an institution where mothers can leave their children during the day in competent hands, with a free restaurant for nursing mothers, a working home for nursing mothers who have no one to support them, a hospital for infants requiring institutional care, and a kitchen for providing food for infants and children, sick or well, and an affiliated dairy and a convalescent home for infants in the country. An institution of this kind would render priceless services to the mothers and medical students as well as to the infants, and through them later to the state. Marfan emphasizes the necessity for all this social service being on the highest plane of efficiency, with a numerous personnel.

63 *Tuberculous Pelvic Peritonitis in Men. J. Duvergey.—p. 117.
64 Passive Mechanotherapy for Sequels of War Wounds. *Guilleminot*, Cistrier and Baudouin.—p. 120.
65 *Persisting Bone Fistulas. R. Bonneau.—p. 124.
66 **Albumin in Hemorrhagic Cerebrospinal Fluid.* L. Boyer.—p. 129.

63. **Tuberculous Pelvic Peritonitis in Young Men.**—Duvergey has encountered several cases of chronic partial occlusion of the bowel in soldiers, with enlargement of the abdomen, febrile periods and loss of flesh. Ordinary palpation of the abdomen gives negative findings. Palpation through the rectum reveals an encysted accumulation of fluid and false membranes filling the small pelvis more or less completely. The compression from the ascitic fluid interferes with bowel and bladder functioning. He cleared out the pelvis through a subumbilical laparotomy, leaving a drain for five or six days. The seven men thus treated seem to be cured completely; the interval since has been two years in some. He warns not to attempt to operate through the rectum on the tumefaction palpated there—the peritonitis should be given the benefit of the laparotomy. This pelviperitonitis is an essentially local and surgical form of tuberculosis.

65. **Treatment of Fistulas.**—Bonneau has charge of a hospital that specializes in treatment of fistulas, and he declares that thorough surgical clearing out of the fistula may be counted on for a cure. In the type of persisting bone fistula leading into a central cavity, with rigid walls, the surgical treatment has always hitherto been inadequate. It is not realized that this central cavity may be irregular in shape, with diverticula or passages reaching for 6, 8 or even 10 cm. The whole cavity, the fistula, itself, and the soft parts around, he says, "are drowned in sclerosis," and the anatomic conditions offer no opportunity for healing and repair even if the cavity is sterilized. The central cavity must be opened up to transform it more into a flat surface; after resection of the rigid tissues, mobilize the normal tissues, muscles, cellular tissue and fat, bringing them as much as possible over the plane surface provided by cutting away a long oval of bone and tissue to expose the central cavity. A head mirror is indispensable, and a strong jet of hot water is useful for washing the cavity clean. There is liable to be considerable hemorrhage unless ample precautions are taken. It may be necessary to sacrifice formidable amounts of sound bone, but this is the price of success. In some cases he had to slice the bone like a sausage over a long segment before sound tissue was reached. The greater the experience, the more generous in sacrificing the bone. The clearing out must be as scrupulously careful as at a mastoid operation. It is sometimes necessary to open up the cavity from the side opposite the fistula, to avoid injuring nerves or vessels, or when the cavity is closer to the surface on that side. It is around this type of fistula, he remarks, that all fistula surgery gravitates. Anything short of absolute thoroughness is bound to fail. He has thus cured men whose fistula had been curetted fourteen times, without curing the lesion, and finally some constitutional disease had been incriminated. Surgeons who practice this thorough *évidement* are unanimous in the optimism of their prognosis, even for fistulas that have been suppurating for two or three years.

66. **Albumin in Cerebrospinal Fluid.**—Boyer refers to hemorrhagic fluid, and says that the proportion of albumin can be estimated by centrifuging and determining the albumin content in the decanted fluid. This removes the red corpuscles. Normal blood averages 5,000,000 or 5,500,000 reds, with about 80 per cent. albumins. The average albumin content of a liter of normal blood, multiplied by the amount of plasma in the specimen of spinal fluid being examined, gives approximately the quantity of soluble proteins from the blood. If 50,000 reds are found in the specimen, then the fraction $\frac{5{,}000{,}000}{50{,}000} = 0.01$ represents the amount of blood in the specimen, and half this, the amount of the plasma present. The albumin in the spinal fluid is thus what is left after subtracting the figure resulting from multiplying 75 or 80 by $\frac{\text{Number of reds}}{5{,}000{,}000 \times 2}$. Of course this method can be applied only with sound reds.

Presse Médicale, Paris

67 *Oliguria of Cardiac Origin. O. Josué and M. Parturier.—p. 421.
68 Identification of Meningococcus in Carriers. P. Papin and H. Stévenin.—p. 423.
69 *Test for Blood. Thévenon and Rolland.—p. 425.

67. **Oliguria of Cardiac Origin.**—Josué and Parturier discuss the clinical consequences of oliguria of cardiac origin, especially the retention of nitrogenous waste and retention of water, the latter entailing hydremia and visceral and interstitial edema. The urine with asystole is scanty, rich in urea, but with little chlorids as the latter are retained to make the retained water isotonic. The urea content of the blood is so high from the oliguria alone that it may suggest pathologic conditions in the kidneys when in fact they are still sound. If the heart recuperates and regains its force, the diuresis returns to normal, and the urea content of the blood drops to normal. Treatment should be addressed to the heart. On account of the oliguria, all the symptoms are deceptive, all the laboratory findings misleading. The first task is to get the heart to pumping normally and induce the liberating diuresis. Digitalis and theobromin are useful whether or not the kidneys are pathologic, supplemented possibly by restricting the intake of salt. When the blood is pumped through the vessels with the normal force, there need be no restrictions as to intake of salt in these cases.

69. **Test for Blood in Excreta and Effusions.**—The test described is based on the color reaction given by pyramidon in the presence of an oxidizer. The reagents are (1) a solution of 2.5 gm. pyramidon in 50 c.c. of alcohol (90 degrees), and (2) a solution of 1 c.c. of crystallizable acetic acid in 2 c.c. of distilled water. To 3 or 4 c.c. of unfiltered urine, for example, is added the same volume of the pyramidon solution, and 6 or 8 drops of the acetic acid solution. After agitation, 5 or 6 drops of hydrogen peroxid solution (12 volumes) are added, and the fluid turns at once an intense violet if there is much blood present. The reaction is slower in developing if there is not much blood, reaching its height in fifteen minutes and then retrogressing. The same technic can be applied to fecal matter; a small amount is triturated with 3 or 4 c.c. of distilled water; after decanting, the reagents are applied as above, as also in examination of gastric juice, spinal fluid, pleural effusion, etc. All the tests

made with this technic were controlled with the Meyer phenolphthalein test, and the findings were constantly parallel. The test is therefore as sensitive as the latter, while the technic is simpler and the reagents more durable.

July 27, 1918, **33**, No. 30

74 *Extraction of Projectiles under Screen Control. Civel.—p. 255.

70. **General Paresis in an Army Psychiatric Center.**—Damaye has encountered in two years 32 cases of general paresis at the center in his charge. There was albuminuria in 11, plus heart disease in 8. In 4 cases shell concussion had brought it on; in 2 other cases a fall or kick by a horse. A number of cases are described in detail; all show the marked improvement that may be realized in the early stages by repose of mind and body, with tonics and mercury later, when the tonics have increased the resisting powers. He insists that dismissal from the military service is imperative, but that the man should be kept for thorough treatment and the family instructed how to continue it at need.

72. **Complications of Vincent's Angina.**—The fusiform bacillus-spirochete infection of mouth and throat may induce eruptions of various kinds, swelling and ulceration in glands in the neck and elsewhere, and all kinds of other septicemic complications, from bronchitis, albuminuria, pericarditis and iritis to congestions in various serous membranes and even pneumonia. Examples of these different types of septicemic complications of Vincent's angina have passed through the hands of Tixier and Tobé. In many instances the complications so outshadowed the "trench mouth" that the connection with the latter had not been suspected. In some cases the ulcerating fusiform-spirochete infection had been overlooked. Treatment has to be local and vigorous, clearing out the ulcerating gums and throat with a 1 per cent. solution of methylene blue or silver nitrate or a weak solution of some arsphenamin preparation. (For treatment see further Campbell and Dyas, The Journal, June 2, 1917, p. 1596.)

74. **Extraction of Projectiles Under Screen Control.**—Civel tells about his work in this line since his first publications on the subject in 1904. By 1916 he had a record of 132 cases in which needles or pins had been extracted by this method and twenty-four foreign bodies in the esophagus, besides many cases of war projectiles. With the screen control it is not necessary to make an incision any larger than is required to admit the instrument for extraction of the foreign body, so that the buttonhole incision under screen control is the main feature of his technic. He claims priority not only for the method but for its application to war projectiles.

75 *Pernicious Anemia in Young Infants. A. D'Espine.—p. 461.
76 Chronic Amebic Dysentery. F. Wanner.—p. 471.
77 *The Cerebrospinal Fluid with General Paresis. I. Osman.—p. 477.
78 Cure of Gonococcus Hydrarthrosis of Knee under Intravenous Injection of Colloidal Sulphur. C. G. Cumston.—p. 483.
79 *Fat Embolism. T. Nakata.—p. 486.
80 Psychosis in Scarlet Fever in Adult. A. Schlesinger.—p. 489.

75. **Pernicious Anemia in Young Infants.**—D'Espine discusses 2 cases of pernicious anemia in infants of 11 and 5 months from private practice. He has previously published 2 personal cases, and a recent compilation lists 56 cases from the literature. This latter group includes 32 cases in which the anemia was traceable to the bothriocephalus or a tenia. Only 2 cases are known of essential progressive pernicious anemia in older children: A girl of 6 died in six weeks after the first symptoms of the hemorrhagic pernicious anemia, and a boy presented simple anemia for several years. It assumed the pernicious type at the age of 13, and he died two years later. There is no verified case on record of pernicious anemia in young infants, and in the 2 cases reported the infants recovered. In the first case a one-sided diet was incriminated, the pernicious anemia being regarded as, to some extent, an equivalent for scurvy. The other child was breast fed. The clinical picture was that of true pernicious anemia in each case except that there was no leukopenia. The recoveries are ascribed to the special serotherapy used. The serum was obtained by venesection of animals at the height of the regeneration of blood following a previous extensive withdrawal of blood. This "hematopoietic serum" seems to have a decidedly favorable action on the composition of the blood, when injected in cases of pernicious anemia. These infants were given daily subcutaneous injections of 5 or 10 c.c. of the serum. It is the result of the researches of Prof. P. Carnot, mentioned in The Journal, at different times. The changes in the blood count, from hemoglobin 20 per cent. and reds 658,875, to 53 per cent. and 2,102,125 reds in nine months, testify to the efficacy of this form of serotherapy. In the first case the hemoglobin rose from 25 to 75 per cent. in a month.

77. **The Spinal Fluid in General Paresis.**—Osman states that in forty cases of general paresis he found large numbers of cells and usually a high albumin content in the cerebrospinal fluid early in the disease. As the disease progresses, the number of cells grows less.

79. **Fat Embolism.**—Nakata injected olive oil or emulsions of human fat into an artery or vein of rabbits, guinea-pigs and frogs. Comparing the resulting phenomena with his clinical experiences in seven cases of fat embolism, shows that fat embolism does not occur in the general circulation in man, or only to a minimal extent. The fat never accumulates in the greater circulation and it rapidly disappears from the blood. In the pulmonary circulation, on the other hand, the presence of fat in the lung vessels was manifest up to eighteen days. Part of the fat injected into an artery or vein accumulated in the pulmonary vessels and lingered there, but the largest proportion of the fat piled up in the liver. The local force of the general blood stream aids in sweeping the fat along.

89 *Symphysiotomy. Y. de Reynier.—p. 1136.
90 *Dinitrobenzene Poisoning. O. Steiner.—p. 1139.

81. **Rupture of Aorta with Chronic Nephritis.**—Löffler reports two cases in a woman of 38 and a man of 43, the spontaneous rupture occurring during sleep in the latter. The heart was much hypertrophied in both cases. The wall at the point of the rupture was not particularly thin. In the woman it spared the outer coat of the artery and did not induce any symptoms. There are a few such cases on record in which the incomplete rupture healed and proved a necropsy surprise.

82. **Tardy Intracranial Hemorrhage.**—In a fall on the stairs the right occipital bone was fractured, but except for vague headache and weakness the woman of 49 showed no symptoms from the contusion for twenty days. Then slight mental confusion, inattention and forgetfulness attracted attention for a few days, then came delirium and stupor, with right lax hemiplegia and left spastic hemiparesis. Necropsy revealed a large hematoma under the intact dura. It covered parts of the parietal, temporal and frontal lobes—evidently the result of progressive hemorrhage from a small branch of the median meningeal artery, the result of the impact on the other side of the skull at the contusion. The case teaches the necessity for exploratory trephining on both sides. In a recent compilation, five of the twelve patients would undoubtedly have been saved if the opposite side had been trephined when the first trephine gave negative findings.

84. **Dermographism of the Thorax with Pulmonary Tuberculosis.**—In testing ninety-six tuberculous men, Ichok found a positive reaction in 68.9 per cent. of the chronic cases, and only in 5.9 per cent. with more recent infection. In thirty cases of recent pleurisy, a positive reaction was elicited in only one. These findings and his analysis of the literature seem to indicate that the dermographic reaction is an indirect index of the behavior of the musculature, as he explains in detail.

85. **Relations Between Lactic Acid and Hydrochloric Acid in the Stomach.**—Rodella's further research has demonstrated that sterile substances covered with pure concentrated hydrochloric acid, if they are not destroyed, remain sterile. But much infected albuminous substances, in solid form and in not too small fragments, covered with hydrochloric acid, not only fail to become sterile but at body temperature strong fermentation occurs. The products of this fermentation may include lactic acid. This responds positively to the Uffelmann test even in the presence of hydrochloric acid. Neither the lack of hydrochloric acid nor the presence of a tumor and its resulting stagnation are absolutely necessary for the production of lactic acid. It can occur wherever there is retention of stomach content, plus the presence of some substances which bind the hydrochloric acid or which protect the fermentable matter against the action of the hydrochloric acid. When these conditions are realized, lactic acid may be formed abundantly in the stomach even without cancer. Prou reported in 1917 that he had found lactic acid in the fasting stomach in 27 per cent. of 300 cases of nonmalignant stomach disease. He declared that the significance of lactic acid needed revision. Rodella will discuss in a following article the relations between secretion of hydrochloric acid and the production of lactic acid as studied from the clinical and from the bacteriologic standpoints.

86. **Necropsy Findings with "Spanish Influenza."**—Only fifteen were females in the fifty-three fatal cases with necropsy, and in all but thirteen cases the patients were absolutely healthy young people between 19 and 30. The oldest was 59, the youngest a year old child. The women were nearly all pregnant or had heart disease. The fatal complications of the influenza are due to mixed infection with pneumococci, streptococci and staphylococci. No influenza bacilli were found at necropsy, even in cases in which they had been cultivated during life from the sputum and sometimes from the blood.

88. **Relations Between Gynecologic Disease and the Appendix.**—On the basis of 896 laparotomies for gynecologic disease, Waegeli concludes that concomitant appendix disease, found in 16.4 per cent., was secondary to the gynecologic lesion in most of the cases. Lesions were found in the appendix in 75 per cent. of the cases of torsion of a cyst in the right ovary, and in 23.7 per cent. of the cases of right tube or ovary disease, but never with left tube or ovary disease alone. Simple congestion in the appendix with gynecologic disease he warns is not enough ground alone for appendicectomy. On the other hand, he urges systematic investigation of the right tubes and ovaries as a routine measure in all cases of appendicitis. This may reveal its secondary character.

89. **Symphysiotomy.**—Reynier analyzes thirteen cases in which symphysiotomy was done, in nearly all as an emergency measure. It does not seem to be any more serious than a forceps intervention. In two of the cases described in detail the symphysiotomy was done under local anesthesia, and it proved to be speedy and free from complications, allowing the birth of a well developed vigorous child. The local anesthesia rendered the symphysiotomy painless, and the labor pains at the following spontaneous delivery were no greater than at any moderately difficult delivery. The fetus at two preceding pregnancies had been removed by perforation or had died soon after induced premature delivery. The true conjugate was 8.5 and 9 cm. but the pelvis was generally contracted. Symphysiotomy was decided on, and the women allowed to go to term, and the results fulfilled all anticipations.

90. **Dinitrobenzene Poisoning.**—Steiner describes seven cases in munitions workers, and comments on the gray discoloration of the mucous membranes and sometimes of the whole skin. The blood looks gray and thick, but the differential count is normal except that there is excessive destruction of reds. In treatment he found useful inhalation of oxygen, free withdrawal of blood followed by infusion of sodium bicarbonate, with stimulants, and copious drinking of milk. The clothes must be removed from the room, and the whole body, especially the hands and hair, must be thoroughly washed with hot water and soap.

92 *Temporary Tubal Sterilization. E. Alfieri.—p. 213.

92. **Operation on Fallopian Tube.**—Alfieri ligates the tube, cuts off the fimbriated end, and pushes the ligated stump into a blind tunnel bored for it in the posterior wall of the uterus, where it is held with two stitches. The procedure is repeated with the other tube, and conception is thus rendered impossible. When the need for preventing conception has passed, the ends of the tubes can be released, and practically normal conditions thus be restored once more. His article is illustrated.

93. **Malignant Lymphogranuloma.**—In both of Jemma's two cases the children of 6 and 11 presented signs of inherited syphilis, and in one the tuberculin test was positive.

94. **Vaccine Therapy of Pneumococcus Infection.**—Pastore applied diplococcus vaccine in eight cases of protracted pneumococcus infectious processes, pyothorax, interstitial pneumonia or migratory pneumonia. Acute pneumonia runs too brief a course for vaccine therapy to display much efficacy, but in these practically chronic cases the pneumococcus lesions in the pleura or the parenchyma of the lung were favorably influenced by this systematic intravenous vaccine therapy. The results were particularly striking in purulent pleurisy. The vaccine seemed to arrest the process and it retrogressed, obviating the necessity for operative measures and even puncture. The little patients were 18 months, 2 and 4, to 9 years old. There was usually a vigorous reaction to the first injection, with a chill, dyspnea and cyanosis but the following injections seldom elicited any appreciable reaction. In others the reaction appeared with the second or third injection, but there were no mishaps of any kind. The vaccine was a suspension of a twenty-four hour culture of Fränkel's diplococcus on a hemoglobinized culture medium. The bacilli were estimated by the opacity of the fluid, and from 0.10 to 0.20 c.c. was used containing from 10,000 to 20,000 of the microbes. Up to eleven injections were made in some of the children.

99 Apparatus to Facilitate Plaster Treatment of Fractured Leg. E. Cavazzani.—p. 708.
100 Tests of Liver Functioning. G. Sabatini.—p. 709.

96. **War Wounds of Elbow and Knee.**—Fasani describes how his extra conservative management of wounds of the elbow during the first years of the war gave such poor results, both in the stiff joints left and the tedious septic complications, that he finally decided to operate at once in the more serious cases. The results were surprising, the pains and fever subsiding under a light aseptic dressing, and passive movements being begun by the fifth to the eighth day. They

can be done by the man himself, and he soon appreciates the benefit from them. Fasani obtained far better results with wounds of the knee when he restricted intervention to a median longitudinal incision, extending it upward or downward as circumstances indicated. The incision is carried through the patella, dividing it in half, and thus affording ample access to the joint without permanent impairment of its functioning. The simplicity of this technic and its great practical usefulness commend it as the best mode of access to thoroughly explore the joint. When resection is inevitable in a septic focus, he cauterizes profoundly the raw surface to make a barrier between the sound tissue and the septic field in which it lies. By the time the eschar drops off, a layer of granulations keeps up the defensive barrier. He also makes a point of refraining from coaptating the resected stumps, but keeps them apart to ensure better draining and permit medication until the septic process has died out.

A wounded artery should be sutured when possible, but a ligature does not inevitably entail gangrene. Fractioned and consecutive ligation may be permissible sometimes. In one case of a traumatic false aneurysm of the femoral artery, there was tardy hemorrhage on several occasions, and he ligated in turn the femoral and the external iliac at different heights. As the hemorrhages kept recurring, he made a transfusion of blood from the man's 17-year-old brother, and this arrested the tendency to hemorrhages and the man soon recovered. The benefit in this case suggests transfusion as a routine procedure with hemorrhages from pseudo-aneurysms.

97. **Premature Blanching of the Hair.**—Lutati relates that the hair of an artillery captain of 24 turned almost completely white during the two days of the battle on the Piave. A young lieutenant had barely escaped being taken prisoner by the enemy and part of the hair on one side turned white in the course of a day or two. In another case a railroad man of 38, after a bombardment of his train, had all his hair, brows and beard drop out. As they grew again, they came in white, but by the end of eight months the eyebrows and beard had returned to the former chestnut color but the scalp hair was still white. Another soldier noticed a long patch of white hairs on the side of his head the morning after a battle. This white strip was still plain eight months later, when Lutati first saw it. He has witnessed further the premature progressive blanching of the hair in several aviators, and this is not uncommon in men who have spent some months at the advanced front. He regards it as an indication of nervous instability, liable to make trouble later. In connection with these cases personally observed, he cites a number of the classic instances on record.

103 Present Status of Bone Grafting. E. Aievoli.—p. 635.
104 Vocational Training of Disabled Soldiers. E. Levi.—p. 639.
105 Antituberculosis Campaign of Italian Red Cross. A. Botti.—p. 643.

101. **Dietetic Treatment of Cancer.**—Centanni does not hesitate to call his experiments here reported "the most important results accomplished to date in modern cancer research." The idea of dietetic treatment of malignant disease is not new, but hitherto the experiments have been made with a diet which starved all the cells. The consequence was that the normal cells were too weak to contend with the cancer cells, and the malignant disease was merely whipped up by the modified diet. Centanni, on the other hand, sought to modify the diet in such a way that it amply sufficed for the nourishment of all the cells, cancer cells included, but the substances in the diet which promote growth were all carefully excluded, and others added which tend to inhibit growth. Modern research has demonstrated a number of food substances which promote growth—he calls them blastins—and he emphasizes that cancer cells do not differ essentially from normal cells except in their "tumultuous multiplication." By depriving them of those elements in the food the fundamental office of which is to sustain the multiplicative function, auxetics, *Wuchsstoffe* or blastins, and for which the cancer cells display exceptional avidity, the tumor cells languish and die. Among the facts which testify to the correctness of this assumption are Haaland's experiences—confirmed by others—to the effect that gestation prevents successful grafting of tumors and checks the growth of those already implanted. The physiologic growth of the fetus victoriously combats the pathologic growth of the cancer.

In Centanni's research he experimented with ninety-three series of from four to ten mice each. On ordinary food, 100 per cent. of the tumor grafts "took" and some grew to be larger than the body of the mouse to start with. Given the restricted diet ten days beforehand, none of the grafts "took" or only feebly grew. On this diet, tumors already established, up to 2 or 2.5 cm. in diameter, became arrested and were finally reabsorbed without leaving a trace. Large tumors softened and decayed to a friable mass. The most striking results were obtained when the main mass of the tumor was resected and the remainder became reabsorbed as the animals were kept on the blastin-free diet. The growth promoting substances are certain vitamins, certain internal secretions and certain chemical substances. In his experimental diet he took particular pains to exclude the antiscurvy vitamin and nuclein and phosphorus compounds, and denatured the food by heating to 125 or 130 C. The outlook for application of the principle to man is promising, as human beings are particularly sensitive to lack of vitamins, while the size of the cancer in proportion to the whole body is immeasurably smaller than in the experiments related. On the other hand, the results will take much longer to become manifest. The method is harmless, as any disturbances from a dietetic deficiency would be recognized early and could be promptly remedied. Experienced medical supervision would be indispensable.

Tumori, Rome

June-August, 1918, **6**, No. 2

106 *Experimental Glio-Fibro-Endotheliomas. D. B. Roncali.—p. 73. To be continued.
107 *Primary Perithelioma of Ethmoidal Mucosa. G. Basile.—p. 115.
108 *Tissue Growth and Tumor Growth. L. Loeb.—p. 127.

106. **Experimental Endotheliomas.** — Roncali's extensive experimental research with inoculation of the toxic products and the endotoxins of pathogenic blastomycetes has apparently demonstrated that no cells are affected by them except those which are in a specially receptive state, that is, candidates for anaplasia. And among these, only those which have undergone some traumatism at the moment of the injection, and when the antigen has come in direct contact with them. These facts were confirmed by injection into the brain of twelve dogs. Two of the dogs died with symptoms of a focal brain lesion the twenty-fourth and thirtieth day after the injection, and a neoplasm was found at the spot consisting of gliomatous, endothelial and connective tissue, evidently malignant. The article is to be continued.

107. **Primary Perithelioma.**—The pedunculated tumor in the nasal fossa had developed from the perivascular endothelium, the so-called perithelium. It had followed a few months after removal of supposed polyps.

108. **Tissue Growth and Tumor Growth.**—This is a translation of Loeb's article in the *Journal of Cancer Research*, summarized in The Journal, June 9, 1917, p. 1781.

110 *Immovable Retroversion of the Uterus. R. R. Ojeda.—p. 41. Conclusion.
111 *Autoserotherapy in Ascites. A. Maya.—p. 57.

110. **Vaginal Operation for Retroversion of the Uterus.**—Ojeda describes with eighteen illustrations the various steps for correction through the vagina of immovable retroversion, and gives a brief summary of twenty-six cases in which this colpoperineorrhaphy was successfully applied.

111. **Autoserotherapy in Ascites.**—Maya has only two cases to report, but the influence from the autoserotherapy was prompt and pronounced. The effect seems to be mainly on the diuresis. In both the women the accumulations of fluid seemed to be passed off in this way. The procedure is harm-

less and is certainly worth a trial, he says, in cases of ascites with still sound kidneys. The ascitic fluid obtained by puncture is reinjected into the cellular tissue, without withdrawing the needle. He injected from 2 to 6 c.c. in this way at three or four day intervals, a total of six and thirteen injections in his two cases. The ascites was of six months' and nine years' standing. The first case was in a woman of 60. There has been no return of the ascites during the seven and nine months to date.

112 *Medical Education in Colombia. E. Ferrero and others.—p. 565.
113 *Technic for Vaccination against Typhoid. M. Mendez.—p. 585.

112. **Medical Education in Colombia.**—The addresses here given were delivered on the occasion of the inauguration of the new buildings for the medical school, mentioned in THE JOURNAL, recently, p. 1238. The speakers were the minister of public instruction, the secretary of the department of public works, and other state officials, besides the president of the medical faculty.

113. **Vaccination Against Typhoid.**—Mendez expatiates on the great value of antityphoid vaccination which has been applied in Colombia on a large scale. But he protests that it is not necessary for every one to be vaccinated, as some advise. Only those particularly exposed to the disease, such as soldiers and nurses, should be systematically vaccinated. He warns further that all persons should be excluded who have fever, albuminuria or signs of tuberculosis, syphilis or Addison's disease. Suprarenal insufficiency is a particularly important contraindication for antityphoid vaccination, as he demonstrates by the case of an army officer. Severe symptoms followed the third injection of the vaccine, keeping up into the next day: profuse sweating, rapid respiration, livid aspect, complete relaxation of the members, distress and frequent vomiting. The man was so sensitive that he winced at the gentlest movement. The pulse was absolutely imperceptible and the heart sounds scarcely to be heard. The temperature in the axilla was 41 C. and there was complete anuria. These symptoms showed no attenuation by the next day, but then epinephrin was injected and improvement became evident almost at once; by the fourth hour the pulse became perceptible. Recovery was accelerated by injection of a solution of glucose. The injections of epinephrin were kept up for a week, by which time the patient was able to leave his room. This was the only mishap encountered in the course of the vaccinations at Bogota.

122 Chagas' Disease. A. M. da Cunha.—p. 108.
123 Dental Alveolar Polyarthritis. C. Lima.—p. 124.

115-116. **Surgery of Stomach and Abdomen.**—These two articles were the last from Wallau's pen before his recent death. He reviewed his experience with thirty-two operations on the stomach, and discussed the best means for draining ascitic fluid and other collections of fluid in the abdomen. He protested against the too prevalent practice of curetting the uterus, relating instances of serious sequels, and styling it a crime *de lesa natureza*, high treason against Nature. He reiterated that Nature created the abdominal cavity a closed cavity, and that this should be respected to the utmost. In one of his cases the ascitic fluid drained into the scrotum like a hydrocele. This was readily punctured as required, relieving the patient from the tapping of the abdomen. In a second case he intentionally accomplished the same with a trocar, drain tube, and urinal. He adds that this would be the ideal method for draining the abdominal cavity if this persisting permeability of the inguinal canal was the normal condition instead of being a rare anomaly.

124 *Dislocations and Fractures of the Elbow. S. G. Hurtado.—p. 3.
125 *Suprarenal Form of Malaria. C. Fraga.—p. 9.
126 Inorganic Heart Murmurs. A. N. Blasco.—p. 21. Conc'n.
127 *The Diet with Cirrhosis of Liver. R. M. Terol.—p. 29.
128 Manic Depressive Insanity. A. Sanchez-Herrero.—p. 37.

124. **Dislocations and Fractures of the Elbow.**—Hurtado gives some roentgenograms of normal elbows as well as of others with fractures or luxations, showing the differences between the adult and infant elbows in both health and disease.

125. **Suprarenal Form of Malaria.**—Fraga reports from Brazil three cases of a set of symptoms indicating acute insufficiency of the suprarenals, and explained by malarial infection. One of the patients was demonstrated at a meeting of the American Society of Tropical Medicine at New York. Necropsy in one case showed the malaria parasites in the capillaries of the suprarenal cortex. The importance of this suprarenal form of malaria is enhanced by the fact that we have in epinephrin a means to tide the patient past the danger point. In the algid form, artificial serum with epinephrin given by the vein, may complete the triumph of quinin. In the less severe cases opotherapy alone may prove effectual.

127. **Diet with Cirrhosis of Liver.**—Terol advises a milk diet in the early stages of cirrhosis of liver. This leaves the liver comparatively in repose while promoting diuresis. He gives nothing but water the first day except a purge. An adult should take 3 liters of milk during the day, sipping a small amount every one or two hours. The milk should never be taken more than this at a time, as this would distend the stomach, with retention and fermentation with results injurious for the liver cells, and digestive disturbances which impel the abandoning of the milk diet. The milk must never be taken raw, but goat's or asses' milk may be substituted for cow's milk. Fermented milk or condensed milk, etc., should not be used except when the patient wearies of the sterilized milk. This milk diet should be kept up for a month. After this the ordinary diet can be very slowly and gradually resumed, keeping to small meals of easily digestible foods. He advises four meals, the two latest at 5 and 9 p. m., but they should never be abundant. Weak mineral waters are useful, avoiding all carbonated beverages as their gas distends the stomach. Mastication should be especially thorough, and the patient should give both body and mind a rest after eating. General and tonic hygiene should be enforced. In cirrhosis with hypertrophy, there is excessive functioning on the part of the liver, and the diet should aim to reduce production of toxins, being restricted to starchy foods and dry vegetables with little sugar or substances liable to putrefy. In cirrhosis with atrophy, meat should be positively prohibited to ward off production of toxins, and salt should be restricted to 6 gm. a day to guard against ascites and edema.

129 *Sugar Content of the Blood in the Tropics and Its Importance in Acclimatization. C. D. de Langen and H. Schut.—p. 1; p. 26.
130 *Nature of Acclimatization. Id.—p. 43.
131 *Glycosuria in the Tropics and "Low Fever." *Id.*—p. 62.

129 to 131. **Sugar Content of the Blood and Acclimatization in the Tropics.**—The extensive researches of de Langen and Schut at Java have demonstrated that in both man and animals the sugar content of the blood is from 30 to 75 per cent. higher in the tropics than in Europe. The seventy-five pages of their report are in parallel columns of English and Dutch. On change to a mountain climate (3,800 feet) the sugar content drops, but it returns to its former figure on return to near sea level. They found further that the sugar content of the blood always ran up, about an hour before a malarial chill and fever, and persisted high during the attack, but subsided anew just before the close of the attack. Quinin did not modify the sugar in the blood directly. They recently reported marked differences between the cholesterol content of the blood in the East Indies and in Europe, and they here refer to other findings which suggest that the calcium content

of the blood is unusually low in the tropics. Low calcium content usually pairs with hyperglycemia, and there is much to sustain the assumption that the infrequency of calcium deposits in the tropics in blood vessels or lungs has some connection with the high sugar content of the blood. They insist that the chemical intensity of the light is no greater in the tropics than in Europe, so the heat must be the main factor. It may act on the sympathetic system; this would explain the high sugar content, the low cholesterol content, and various other factors which enter into the process of acclimatization. If we accept this hypothesis of sympathecotony as an important element in acclimatization in the tropics, then it follows that measures to reduce the hypersensitiveness of the sympathetic system are required. Chief among these is the administration of calcium chlorid. With this can be prevented hyperglycemia and hyperthermia in animals given a drug which otherwise promptly sends up the temperature and the proportion of sugar in the blood. When the sugar content of the blood is increasing on arrival in the tropics, higher demands will be made on the kidney filter, and some of the sugar may be cast off in this way—a true renal glycosuria. Another way for the body to get rid of the excess of sugar is by combustion, and de Langen and Schut are convinced that the majority of cases of long persisting "low fever" in persons not acclimated to the tropics can be explained in this way. The "low fever" to which they refer is not a disease; not a single abnormality can be detected. The complaints are the same as with renal diabetes, and both yield to the same measures, namely, change to a cooler climate or administration of calcium. A sea voyage is a sovereign remedy for "low fever," but it has not been tried for renal diabetes, they believe. They emphasize in conclusion that persons inclined to renal glycosuria, the tuberculous, and those displaying sympathecotony, should be warned against settling in tropical regions, at least near sea level. On the other hand, a healed apical tuberculous process in persons of the vagotonic constitution need not be a contraindication to life in the tropics.

134 *Spondylitis Deformans. G. Kahlmeter.—p. 169-405.

134. **Deforming Spondylitis.**—Kahlmeter was assistant for two years at an asylum for the aged and incurable, and he examined with the roentgen rays every inmate that presented the slightest stiffness or pain in spine or hip joint. There were twenty-three typical cases of deforming ostearthritis of the spine, and he further examined with the roentgen ray thirty-four cases at other institutions, and studied the roentgeonograms taken for other purposes in 1,056 persons. The necropsy findings are shown in two colored plates, with fifty-six roentgenograms. Every one in two or three of the elderly presented the characteristic lesions, but they were extremely rare under 40. Four times more men were affected than women. The stiffness and pains do not seem to be associated with these processes, but to be the result of the weakening of the spine which always inaugurates the deforming osteoarthritis. The symptoms from this insufficiency of the spine may precede any pathologic anatomic changes. On the other hand, the characteristic pathologic anatomic changes may in time correct the insufficiency of the spine, and then there will be no further pain. He emphasizes that the process does not spread over much of the spine, and that the disturbances are remittent, so that the earning capacity may be only periodically impaired.

Treatment addressed to the stiffness and pains may include baths, massage, passive exercises, application of heat, revulsion to the skin and other antineuralgic measures. He found bed rest and local heat to the part of the spine involved the most effectual of all symptomatic measures. He explains the pathogenesis as the consequences of the displacement of the weight-bearing balance of the spine on account of some disproportion between the weight to be borne and the weight-bearing power. This assumption suggests the necessity for measures to restore the normal balance in the spine. This would not only relieve the subjective disturbances but it might arrest the further progress of the disease or prevent the development of the characteristic pathologic process. It can be accomplished by reducing the weight to be borne, or by strengthening the supports, especially the muscles that sustain the spine. Massage and gymnastics are useful for this. The strain on the spine may be reduced by change of occupation if it compels carrying heavy articles or bending over, or by reducing the body weight in case of a tendency to obesity (some of the clinical cases reported show the marked benefit from measures of this kind taken unconsciously), or supporting corsets may be worn. One of his patients was materially relieved by a leather corset. He was able to resume his work as a carpenter for a year and a half to date, free from all disturbances, but they return whenever he discards the corset.

137 *The Abdominal Walls with Gynecologic Disease. S. A. Gammeltoft and G. Wiltrup.—p. 1291.
138 *Croupous Pneumonia. C. Lundsgaard.—p. 1308.
139 *Calomel in Treatment of Pruritus Ani. O. Hamburger.—p. 1316.

135. **Hematoma Impeding Delivery.**—Petersen and Tofte report four recent cases of a hematoma developing in the vulva or vagina in the course of a childbirth and preventing its completion. It was necessary to incise the hematoma and, after the child had been delivered, ligate the bleeding vessel when it could be found, suturing the incision to fully obliterate the cavity.

137. **Changes in Abdominal Walls with Mild Gynecologic Disease.**—Gammeltoft and a massage specialist call attention to the patch of tenderness in the abdominal walls that may sometimes be the only sign of latent disease below. They give the details of seventeen instructive cases of the kind. Palpation of the abdominal walls revealed changes in the subcutaneous tissue or the muscles, and by massaging at these points conditions returned to normal both in the abdominal wall and below. It is indispensable to palpate the abdominal wall itself in examining for disease in the internal genitals. If tender spots or palpable lesions are found, this shows the points where massage or other measures should be applied, and with this the patient's symptoms may subside completely. It is possible that the innervation of the tender patch is by a branch of the same nerve innervating the diseased area below, and the superficial tenderness is induced by reflex action from the lesion beneath. This persists after the deep lesion has completely retrogressed.

138. **Pneumonia.**—Lundsgaard describes the research and the clinical experiences at the Rockefeller Institute Hospital at New York, during his fourteen months of work there. He adds that croupous pneumonia seems to be less prevalent in Denmark and less fatal than in New York. The death rate at Copenhagen averages from 18.3 to 25.9 per cent. but it was only 13.1 per cent. for children between 5 and 15, and 20 per cent. between 15 and 65. Above this age it averaged 68 per cent.

139. **Calomel for Pruritus Ani.**—Hamburger states that several physicians have expressed their gratitude for the relief from long standing pruritus ani by his method of rubbing dry calomel into the parts. When the calomel is rubbed in well it sticks till the next day. In salve form, he reiterates, it cannot be counted on for such effectual service.

ETIOLOGY AND TREATMENT OF PRURITUS ANI

SUMMARY OF EIGHT YEARS' ORIGINAL RESEARCH WORK[*]

DWIGHT H. MURRAY, M.D.
SYRACUSE, N. Y.

With the exception of cancer, there is probably no disease that afflicts mankind the etiology of which has been so little understood as pruritus ani, vulvae and scroti. I might say that few other diseases have baffled the profession in its efforts to relieve patients as seriously as this.

In every book that contains a chapter on the subject, it is asserted that nearly every disease to which flesh is heir is a cause of pruritus ani, yet the recovery from the original diseases has left them with the same old pruritus. It would seem, therefore, that the profession might have formed a logical conclusion, eliminating nearly all of the so-called causes of pruritus ani, when it was seen that it continued after the disappearance of the various diseases that were supposed to have caused it.

For many years when the American Proctologic Society held its annual meetings, the members asked each other if there was anything new as to the etiology or successful treatment of pruritus ani and the answers were always along the line of continued speculation as to the causes, and empiricisms for treatment, with negative results.

For a number of years I investigated various conditions that I thought were causes, only to find that my theories, when fully tested, were not tenable. In the summer of 1910, an unusual circumstance led me on a line of investigation different from any I had ever followed, which had a bacterial origin in view. I made cultures of the anal skin with the thought that if any bacteria were constantly or nearly constantly present, this might be a step toward a better understanding. My associates and I found that in the first four cases, the patients had *Streptococcus fecalis* as the only constant organism.

After serious consideration I decided to have an autogenous vaccine made from *Streptococcus fecalis* and test these four cases with it. Meanwhile, other patients with pruritus ani came and the cultures in every one showed *Streptococcus fecalis* as the only constant bacteria present.

During the year, definite improvement in these cases, with the use of autogenous vaccine, was noted. In fact, I was at first dumfounded that we should get such good results, but this was before I had sufficient experience in the work to reason out cause and effect, while today from my past clinical experience, it is not difficult to understand the reasons.

In the cases of patients that came to me before this discovery, I had made an abject failure to bring about any real improvement from either treatment or operation. In fact, I had become so pessimistic as to results of treatment or operation that when these patients came, I frankly admitted to them that I had never been able to give benefit, and either tried to send them to some other physician, or discourgae them so that they would voluntarily excuse me.

BACTERIOLOGIC EXAMINATIONS

Our bacteriologic reports show that a skin infection is the cause and when we know that the common symptoms both subjective and objective are almost identical in all cases, this alone gives strong support to the bacteriologic etiology.

The first side investigation that followed was an examination of the blood to determine its phagocytic power against these bacteria. In every patient examined the coefficient of extinction of opsonins for *Streptococcus fecalis* was low, while in patients who had other rectal diseases, without pruritus, it was normal. We found that when the phagocytic power increased, by the use of autogenous vaccine, the itching ceased proportionately, the improvement as a rule being manifested by less frequent attacks and a lessened intensity of the itching. As they improved, many patients said that if itching began they could rub or scratch the parts with relief, the same as when itching occurred on any other part of the body, instead of being compelled to dig at the parts until they were sore and bleeding, as had formerly been necessary.

Textbooks written by some of the ablest men give as causes of pruritus ani all dietetic faults as well as all local pathology of the anal canal. In order to prove whether these claims were true, I examined the history and pathology of 900 consecutive rectal cases from my own records and found that only ninety-four patients had complained of pruritus ani. A year later, Dr. T. Chittenden Hill of Boston made a similar investigation of 3,000 rectal cases treated in the Boston City Dispensary and taken from his own private records. He reported 320 cases of pruritus ani among them, which is the same percentage I found. This of itself is strong evidence that pathologic conditions in the anal canal cannot be the etiology of pruritus ani. If so, we should have far more than 10 per cent. of the cases in all rectal pathology.

Of the patients examined that had pruritus ani I found that 50 were constipated, 5.5 per cent. of the

---

[*] Read before the Section on Gastro-Enterology and Proctology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918

900 patients examined; 21 had hemorrhoids, 2.3 per cent.; 20 had ulcers, 2.2 per cent.; 23 had diseased crypts, 2.5 per cent.; 12 had hypertrophied papillae, 1.3 per cent.; 3 had polypi, 0.03 per cent., and 3 had fistula, 0.03 per cent. The skin of 15 was pigmented, 1.7 per cent., and 68 had excess of moisture, maceration and skin fissures, or 7.5 per cent.

ETIOLOGY

It seems to me that my records prove that none of these diseased conditions may be properly classed as causative of pruritus ani, but when present are coincidental. My case records show that there is no other rectal pathology of any account, etiologically, in 90 per cent. of the pruritus ani cases.

We have abundant proof that food has nothing to do with the etiology, though some foods may provoke attacks of itching and the patients may improve under vaccine treatment just the same, whether they are on a full mixed diet or not.

Cases of pruritus ani, complicated with fistula having a pus discharge on the anal skin, have been relieved by autogenous vaccine treatment while the fistula was still discharging, and I have found that when rectal pathology is present with pruritus ani, an operation for its radical cure does not relieve the itching for more than a few weeks, if the streptococcic infection is present.

In other patients having rectal pathologic condition and itching, but without streptococcic infection of the anal skin, an operation for the cure of the rectal pathologic condition permanently relieved the pruritus. Only two cases of this kind have occurred in our series of 185 cases, while at least a dozen patients have relapsed as to the pruritus ani when operated on with the infection present.

It has been demonstrated to my satisfaction that operations do not cure pruritus ani when skin infection is present. Some surgeons make the assertion that operations cure pruritus ani, but I find that after the patients have been operated on, they are free from itching for a few weeks at most, when it returns with increased severity.

Two of the conclusions in my third annual report were as follows:

> The presence of skin infection with a local lesion begets an unfavorable prognosis for the cure of pruritus ani as a result of operative procedure, and, the absence of demonstrable skin infection with pruitus ani, in the presence of a local lesion, will justify making a favorable prognosis for the cure of the pruritus as a result of operative procedure.

Pruritus ani rarely, if ever, extends above the white line of Hilton. This is another proof that pathologic conditions in the anal canal are not a basic cause. The pruritus of diabetics is not in any way connected with bacteriologic pruritus ani, except as a coincidence. Many textbooks state, and the majority of the medical profession believe, that the moisture present in these cases is due to mucus that leaks through the sphincter on the anal skin.

If you examine the skin through a magnifying glass you can see the moisture collecting on the diseased skin, but you cannot see it on the normal contiguous skin. Experience has proved that the moisture is a result of the low grade inflammation of the skin, caused by the infection, and never comes from inside the anal canal unless there is a patulous anus, and even then it is not the same kind as the skin exudate. This is usually caused by some ambitious surgeon who thinks he can cure the pruritus by doing a Whitehead operation, "Ball's operation," divulsing the sphincter muscle, or some other equally inefficacious procedure.

The statement that pruritus ani is the result of skin infection has led some to misinterpret its full meaning, that is, to believe that the bacteria affect only the *surface of the skin*, and to apply a local treatment that is of little effect or that may be a positive damage to the patient.

To illustrate this, I quote from Mummery's[1] last book in which he states he has tried the autogenous vaccine treatment in several cases with a certain amount of success. He then says:

> It seems to me, however, that if the streptococcic infection of the skin which is undoubtedly present on testing in many of these cases, is the cause of the itching, the best method of getting rid of the infection is direct local application rather than the use of autogenous vaccine. We are not in the habit of using autogenous vaccine to sterilize a patient's skin before operating as we have other and more effectual methods.

TREATMENT

He describes a local treatment by a 2 per cent. solution of iodin in a 75 per cent. rectified spirit, which he drives into the tissue by cataphoresis. This indicates that Mummery overlooked the crucial point of the discovery, that is, that the coefficient of extinction of opsonins in all pruritus ani cases is low for the infective bacteria and that they are found in the skin as well as on its surface; therefore any local treatment that does not increase the phagocytic power of the blood against these germs can have only a very temporary effect. Many physicians are of the opinion that the skin fissures are caused only by the finger nails. If this were true, the parts would not show so many common characteristics, but instead, distinct markings of the finger nails that would not be quite the same in all cases as we now find them.

Other local applications have been used with the same idea in mind and with similar results, such as treatment by the roentgen ray, radium, and other applications that could kill the germs in situ. I have cared for some patients on whom the roentgen ray had been applied to the extent of local burning and sloughing. The pruritus did not improve, but was made materially worse, *notwithstanding* the burning of the tissues which certainly must have killed the germs then present, but it did not increase the systemic resistance to infection.

The loss in skin pigmentation is a result of the maceration and the bacterial action on the skin. The bacterial infection takes the elasticity out of the skin so that it is like parchment, easily fissured, and the fissures nearly always follow the direction of the skin folds. In severe cases of long standing the skin will break with slight straining much the same as old rubber. The elasticity and resilience have been destroyed by the action of the bacteria and the resultant inflammatory process. With autogenous streptococcus vaccine treatment the phagocytic power is raised, then the excessive itching, moisture and skin fissures gradually disappear, pigmentation returns and the skin seems to resume its elasticity.

---

[1] Mummery: Diseases of the Rectum, New York, William Wood & Co., 1914, p. 241.

Last year I directed the treatment of a New York physician. He had been treated with roentgen ray; the skin about the anus and the abdomen as far as the umbilicus was burned so that he had extensive sloughs. The pruritus and this treatment had incapacitated him for a considerable time and caused the most intense suffering. When healing began, the itching returned with increased intensity. It was at this time that I was appealed to and advised autogenous vaccine.

After a few weeks' treatment I received a letter from him, the conclusion of which I quote:

> Sept. 18, 1917. In conclusion I can report definite improvement in the intensity and frequency of the pruritus. As I am now back on duty we shall be able to judge how matters stand during the exactions and activity of the daily routine work.

Nov. 7, 1917, a report came from his physicians saying, "Dr. —— is fine."

I have now examined 181 cases of pruritus ani bacteriologically and have found *Streptococcus fecalis* as the common germ in 168 of them. Of the thirteen in which *Streptococcus fecalis* was not demonstrated, twelve had only one or two cultures taken and the thirteenth case, an acute one, developed an abscess in the perineum and had no more itching after this was operated on. It is therefore not at all certain that these twelve patients are not infected, because, in a considerable number, *Streptococcus fecalis* was not found until as many as eight or nine cultures had been taken. Therefore the bacteriologic results of these twelve negative cases cannot be considered final.

The reason I did not find *Streptococcus fecalis* in the twelve was probably because the mediums were not properly made. Sometimes the plates are overgrown with other bacteria that choke out *Streptococcus fecalis.*

I have treated 113 of the 181 patients, and distinct relief was obtained in ninety-nine of them. Some of those in whom the greatest relief was experienced were among those with the most distressing cases. Thirteen of them received little or no benefit, but only four of the thirteen received a sufficient number of treatments, so that they should have had relief, according to our experience with the others. Two of the four had the worst vulvar involvement of any I have ever seen, while a third one of the four had a complicating eczema.

The other nine had only a few treatments each, became discouraged and discontinued treatments. They expected too much.

METHOD OF TAKING CULTURES AND APPLICATION

I shall give in an abbreviated way the method of taking cultures and the treatment used. The anal skin should be carefully washed with a weak soap and water solution and rinsed with plain sterile water. No alcohol or other drug is used. A sterile swab is then rubbed on the cleansed anal skin, especially over any skin fissures that exist.

The isolation of *Streptococcus fecalis* is accomplished as follows: The swabs received are gently but firmly rubbed over the surface of solidified standard beef infusion agar in Petri dishes. The agar should have an acidity of 0.5 to phenolphthalein.

The small clear colonies of *Streptococcus fecalis* are readily distinguished from the larger colonies of *Bacillus coli, Staphylococcus albus* and other bacteria encountered in such cultures.

The small colonies of *Streptococcus fecalis* are subcultured on slants of the same kind of agar as that used for isolation.

As a rule, the growth is rapid and luxuriant and a few tubes suffice for the amount of bacterial vaccine desired. However, some strains are encountered that are grown with difficulty.

The bacteria should be killed either by 0.5 per cent. phenol (carbolic acid) solution or a 0.33⅓ per cent. tricresol solution. Heat should not be used.

After the vaccine is proved sterile, it is ready for use and should be kept in a sealed bottle in a cool place. At the time of using, the vaccine should be thoroughly shaken in order that the dead bacteria may be evenly distributed in the dose given.

I begin the dosage with 3 minims, injected into the buttock close under the skin, not into the muscle. The first three or four doses are repeated at intervals of two days, increasing from 3 to 5 minims each treatment, unless a severe reaction is caused by the previous dose. The number of minims at each treatment may then be increased as much as the judgment of the operator dictates. The results will be obtained in most of the cases just as well without local applications of antipruritics except for the temporary relief obtained.

RESULTS

I never promise permanent relief, and do not think it is advisable to do so, no matter how favorably the case progresses, because I have never found what it is that primarily lowers the phagocytic power of the blood so that the original infection occurs. Therefore, if the same condition that originally lowered the resistance remains and again reduces the phagocytic power, conditions favorable for reinfection will be present. If this occurs, the patient must take another course of vaccine treatment to bring the phagocytic power back to normal.

My records show that a majority of the patients who have taken this treatment with favorable results have never relapsed to as severe pruritus as they originally had, and I look on this as a physiologic endorsement of the claims put forth for both the eitology and the treatment.

This was emphasized recently in Case 1 of our series, when the patient (now living in California) came into my office. He reported that he had very little itching at any time and if it did come on, it was easily controlled. This patient had twenty-seven treatments, the last of which was administered five years ago.

A fair question and one frequently asked is: Why is one person afflicted by pruritus ani and another free from it, since the same bacteria are found in the feces of both? We find that the resisting power against these bacteria is below par in the patient afflicted so that the soil in his case is ready while the other has the normal phagocytic power and resists the infection.

POSSIBLE PREVENTIVE MEASURES

The usual method of cleansing after a stool is by using dry paper as a detergent, with which it is impossible to cleanse thoroughly. You can easily demonstrate this by using a moist cloth after you are supposed to be thoroughly cleansed with paper, a method that leaves the fecal matter on the skin between the nates. This skin is an efficient incubator at a proper temperature with just enough moisture for the rapid growth of bacteria, and on account of being kept in contact with the parts, affords an opportunity for them to find a home in the skin. If there is any possibility of prevention it must be along the line of cleanliness after defecation, as outlined. In women, for prevention of pruritus vulvae, the cleansing should be from the front backward. This is seemingly such an unimportant matter that some may think it unnecessary. I believe that this manner of cleansing would also repay many women by the prevention of a *B. coli* cystitis.

CONCLUSIONS

1. From the data presented by this series of cases, I feel justified in saying that pruritus ani is caused by an infection made by one of the streptococci group, or associated with it. This infection may be the primary, secondary, or aggravating cause. If it is the secondary or the aggravating cause, the primary may already have passed away.
2. Whether the infection occurs because the opsonins for streptococci are low or whether the opsonins are lessened because of the invading organism is not yet known.
3. Statistics of 4,000 distinctly rectal cases show that 414 (about 10 per cent.) had pruritus ani. This is good evidence that, when rectal disease and pruritus ani occur together, it is only a coincidence. When there is pus or other discharge on the skin about the anus, pruritus ani does not often exist unless there is a skin infection.
4. Pruritus vulvae and pruritus scroti are also proved to be skin infections.
5. Pruritus ani rarely extends above the white line of Hilton.
6. The sphincter muscle does not allow leakage of mucus on the anal skin in one who has pruritus ani unless there is a patulous anus, any more than it does in a patient with a normal sphincter muscle who has no pruritus.
7. The skin moisture is produced locally and is due to the low-grade inflammation of the infected skin.
8. The presence or absence of bacterial infection is of great prognostic value if operative work is expected to cure.
9. Pruritus ani will not be improved unless the phagocytic power of the blood is increased, and the pruritus will return if the phagocytic power of the blood is again lowered enough to allow a reinfection.
10. A complicating infection may be present.
11. Pruritus ani, pruritus vulvae or pruritus scroti are not a part of a diabetic condition. When they occur with general pruritus, it is a coincidence.
12. The only possible method of prevention lies in bathing the anal skin after each defecation.

ABSTRACT OF DISCUSSION

Dr. J. M. Frick, Toledo, Ohio: My own experience in the treatment of pruritis ani with autogenous vaccine began five years ago. Great care must be taken in selecting the case as one of true pruritis ani. It is not at all infrequent for an eczema marginatum or some skin infection to be referred to as a pruritis ani, which, of course, would not respond to true pruritic treatment. Among 4,700 candidates for selective service I found pruritis ani to be the most frequent proctologic disease. I have complete records of forty-three private cases. All these patients exhibited the typical skin changes. Twenty-five exhibited no other coincidental pathology; eight exhibited other coincidental pathology; ten had been operated on previously for coincidental pathology, with the theory of producing a cure of the pruritus. Forty were sent to the same laboratory for cultures. Three were treated with autogenous or stock vaccines. Of the forty cultures thirty-eight were positive. One culture was a pure colon bacillus, one a mixed streptococcus culture.

Dr. Dwight H. Murray, Syracuse, N. Y.: How many cultures were taken of those cases?

Dr. Frick: We take only one culture. It is not necessary to get more than one culture. Four patients did not return for treatment, leaving thirty-six treated with the autogenous vaccines and three treated with stock vaccine. Of the thirty-nine treated, thirty-seven have been discharged as cured. Four of these have remained cured for a period of four years. One patient received no benefit, or reported no benefit. One patient was insufficiently treated, owing to moving out of town. Three cases recurred; two cases recurred after a period of one year, and one case recurred in six months. One of the former, and the latter case, are now under treatment. One of the first cases that recurred was a case treated with stock vaccines. Later we had a culture taken and an autogenous vaccine made, and that patient is now doing very nicely. The two remaining cases treated with stock vaccine have remained cured.

Our culture medium differs somewhat from the technic used by Dr. Murray. We have used from the beginning of our work the ascitic fluid of Rosenow.

Dr. E. Eliot Harris, New York: I would like to ask Dr. Murray how often he repeats the injections; also the interval between them, and, further, if he could tell us the strength of the solution he uses and the number of bacteria in each injection.

Dr. J. M. Rector, Columbus, Ohio: I should like to have either Dr. Murray or Dr. Frick tell us something more about the culture. Dr. Frick spoke of Rosenow's agar, and I wish he would tell us something more about that.

Dr. J. M. Frick, Toledo, Ohio: The area is prepared first by soap and water, flushed off with sterile water and dried with a sterile gauze. Remember, the infection is deep, not superficial. We remove the surface just as you would in the ordinary vaccination, without drawing blood, taking the culture on the platinum needle and placing it in the ascitic agar of Rosenow.

Dr. James A. Duncan, Toledo, Ohio: I have had only a limited experience following the method of Dr. Murray. There were nineteen cases in all; seventeen of the nineteen were what we called cured, and cured permanently, we hope, while two were cases in which there was no benefit to the patient. In one case the skin had been washed with alcohol instead of soap and water, which I believe to be the cause of the failure. The other case was one in which I did not curet deep enough. Following that I have had no failures.

Dr. Thomas Charles Martin, Washington, D. C.: We have heard only one side of the question. I believe it is not claimed by Dr. Murray or his exponents of this method that they get 100 per cent. cure by the Murray method.

Dr. Murray: That has never been claimed.

Dr. Martin: And is it not also a fact that in nearly all the reports of cases of treatment of pruritis ani by this method other means have also been employed in the treatment of these patients?

Dr. Murray: You mean at the same time?

Dr. Martin: Yes.

Dr. Murray: Very rarely.

Dr. Martin: I asked that question because I thought the answer would be somewhat different. It is a part of parliamentary practice, of course, to exercise that kind of caution. My reason for anticipating that Dr. Murray's statement would not be what it is is the fact that I have not seen the more recent of his papers; but the early case reports I remember also mentioned other means of treatment as being applied. It was very proper to do so because those methods had yielded good results. However, from the scientific viewpoint, such reports tended to confuse the mind as to on what depended the result. Dr. Murray has not only talked to you about the autogenous or vaccine treatment of pruritus, but he condemned another method of procedure, a method of procedure which, if employed by hands equally skilled as those which applied this method of vaccine treatment, does yield 100 per cent. of cures. I refer to surgical intervention. The operation is termed the Ball operation. It consists in dividing the cutaneous nerves that supply the circumanal skin. The operation consisted in making an incision on either side of the anus, going through the skin, cutting off the nerves in the loose connective tissue between the skin and deeper structures. For many reasons that method of incision was not very satisfactory mechanically. Later, Dr. Krause of Cincinnati and I designed an operation requiring no suture. This technic has not been published. I make an anterior and posterior incision and cut the nerves supplying the skin. Dr. Murray makes the statement that Ball's operation or any modification of it is to be condemned as useless, often leaving the patient worse than before. I do not condemn Dr. Murray's method of treatment of pruritus ani. But until this time I have yet to be persuaded that it is as dependable a method of procedure, or as positive in its effects, as the surgical operation.

Dr. Anthony Bassler, New York: The doctor's case cited by Dr. Murray is the ninth case that I have had to do with that has been treated thoroughly, all of the patients having gotten well except one, and that one is very distinctly improved, but having to use some local means about every six months or a year.

Dr. Dwight Henderson Murray, Syracuse, N. Y.: So far as I know, Dr. Martin is the only man who has ever had 100 per cent. cures in pruritus ani from operative procedure. I have seen many cases of pruritus ani in which operation has been performed in the hope of a cure, and the story was always the same. They were free for a little while, just the same as the patients on whom I have operated, but the pruritus returned. I used the autogenous vaccines with great lasting benefit. I have never yet said that I cured a case of any kind. I do not believe it is the province of any physician to claim that he cures his patients. Possibly they get well in spite of him, and he should not take unto himself all of the credit that Nature ought to have. In all the papers that I have written on this subject I have only given the facts as I have found them. I have not said that autogenous vaccine cures any patient. The primary claim that I make is that we have found the etiology. I believe this to be a great step in advance.

In all of my papers I have asked the profession to cooperate with me to find some better treatment, something that will stop the itching for all time, that will enable us to say definitely that the itching will cease at a definite time. I have urged the profession to help, and I will welcome all improvements on present methods that will assure patients a hundred per cent. cure. I do not see how Ball's operation could benefit pruritus scroti, complicated with pruritus ani.

In answer to Dr. Harris' question, I usually begin with 3 minims, and as near as possible the standard strength of vaccine, 2 billions of dead germs per cubic centimeter; the second dose is double the amount, the third dose 3 or 4 minims increase over the last. The dose is increased each time until a strong reaction is produced. The first improvement noted is a less frequent and less intense itching.

Dr. Harris: How frequently are the doses given?

Dr. Murray: Every other day for the first four or five doses, until the reactions appear.

Dr. Harris: How many doses do you give?

Dr. Murray: The number varies. I have given as many as seventy and as few as seven.

Dr. J. M. Rector, Columbus, Ohio: Is it necessary to make the injections near the rectum?

Dr. Murray: No. I make them in the skin of the buttocks. In the last few years, whenever I make local applications on the skin, it has been 20 per cent. protargol; and if I advise the patient to do anything in the meantime, it is usually to apply black wash, let it dry and then dust with compound zinc stearate.

Dr. Martin: Do you use other methods than the vaccine?

Dr. Murray: Frequently, but not in every case. Some of these patients are treated without any application at all, and they have improved, just the same as the others. Most of these patients have used ointments of some kind, but I condemn the use of ointments. They are dirty, they macerate the skin, make it worse than before and do very little, if any, good. Many patients are opposed to any sort of operation, and in some cases in which the Ball operation has been done a stricture was grafted on the original disease. Perhaps Dr. Martin will say this was due to an inexpert operator, but Dr. Ball himself abandoned it as ineffective, I am told.

THE SUBNORMAL COLON FUNCTION *

WILLIAM M. BEACH, M.D.
PITTSBURGH

The colon, considered in its entirety, is essentially an organ of elimination and resorption. Its muscular wall endows it with the property of expansion and retraction, and the variation of its axis and caliber controls the current of its contents toward the anus. Deviation from this physiologic process is recognized as a pathologic condition which may manifest itself in frequent discharges, or by sluggishness. Hyperactivity would indicate an exaggeration of its function by virtue of disease within its chambers or upper tracts, that is, it may be extramural or a neurosis. Sluggishness or atony signifies its inability to mobilize its contents by reason of impaired musculature or innervation, giving rise to the adynamic or subnormal colon. The word "atony," which seems best to express the condition, is derived etymologically from the Greek word "teinein," negative "a," which signifies literally to stretch, a translation that we may liberalize into expansion, contraction and retraction—in short, having the property of elasticity. With the negative prefix, the term is made to mean inertia, or want of power or vigor. Atony is applied to any organ giving evidence of want of vigor as to its function. It is a question whether we should not limit its application to structures not under the control of the will. The muscular structure of the colon is made up entirely of unstriped or involuntary fiber, hence its subnormal function must be due to some inherent factor.

FACTORS IN SUBNORMAL COLONIC ACTIVITY

What constitutes the normal function of the colon? It is debatable what intervals in its evacuation maintain the standards of health, and whether daily periods, alternate days, or longer periods of constipation are compatible with well-being. Metabolic disturbance is apparently not in evidence even in three day constipation or with intestinal inertia of a week's duration. While it has been frequently observed that shorter intervals are conducive to ill feeling and depression, such cases are easily corrected by ordinary measures of diet, exercise and various remedies. But the severe types should receive the best care at our command, to obviate all possible sequelae terminating in destructive metabolism. It is obvious that the vicarious elimination of toxic elements due to physiologic insufficiency of the colon so impresses us with deleterious end-results that we are impelled to regard a daily, or at most a bidaily evacuation, as a necessary corollary to health. Some one has said that a daily visit to the "throne of Cloacus" insures one's life that day. With this in view, let us inquire into a few of the many factors that lead to subnormal colon activity: (1) structural deviations; (2) bacterial invasions; (3) occupational influences.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

1. *Structural Deviations.*—The cardinal symptoms of the subnormal colon record the presence of mucomembranes, constipation and pain. Glénard himself well describes the disease named in his honor: "Flabby abdomen, outspread like a wallet, looseness, slackness, want of tone of the abdominal walls, bearing down of the bowels and subsequently of the stomach, the kidneys and the liver; and, as may be verified by palpation, either the dilatation or the shrinking of certain portions of the intesine and pulsation of the abdominal aorta." This is the physical picture we adopt in our present consideration.

It is not my purpose to discuss the pros and cons of the antecedents in visceroptosis in its relation to mucomembranous colitis. The inactive colon may exist without enteroptosis. Also, it is certain that enteroptosis may be seen without colitis, but in all serious cases they coexist. The most careful clinical observation can elucidate these problems. It is well to think of some primitive disturbance in the nervous system, or in some predisposition of the economy, by virtue of which intestinal atony, then colitis and enteroptosis may originate on a common basis. The order of sequence matters little. The pain is shifting and accompanies the spasm, occurring in colonic sections, at the angles, then in the sigmoid, the transverse or the caput coli. Spasm of the colon head has led to error in diagnosis, with subsequent removal of a healthy appendix. In examining the large intestine, we find alternate dilatation and constriction, hardness of certain segments and flabbiness of others, displacement of the transverse portion, and gurgling and sonorous splashing, with dull lapping sounds elsewhere. Palpation is frequently painful. The roentgenogram reveals sharpened lateral angles and retarded fecal excursions.

In addition to structural deviations in the bowel itself, the clinician must conjure with certain extramural agencies which provoke the subnormal colon. Bands and adhesions, or a dislocated kidney or stomach combine to irritate the colon. Adhesions succeeding pelvic peritonitis and appendicitis are not uncommon, as well as new growths deflecting normal colonic function. To these may be added anorectal diseases obstructing the evacuation of the colon content.

2. *Bacterial Invasions.*—The colon is a great storehouse for toxins and fortunately is immune in most persons, but repeated mass attacks make dents in the mucosal column of defense, which requires the highest strategy of the clinician to restore. If the first line of defense, the mucosa of the colon, is disabled, the second and third lines, the liver and the antitoxic glands respectively will come to the rescue to neutralize the toxemias. The source of bacteria entering the colon may be the mouth and the gums, the pylorus, a diseased gallbladder, the appendix or any of the pelvic viscera. Besides, bacteria are created in the intestine itself, *sui generis,* by end-products of digestion, and the anaphylatoxin present in certain toxemias, both convulsive and nonconvulsive in character, depend on certain conditions of stasis in the intestine.

3. *Occupational Influences.*—The subnormal colon is rarely found among rural folk. Their active lives in physical effort, with pure air and food, mental contentment and freedom from much worry, are compatible with active secretion and elimination. On the other hand, the anxiety, fear and sacrifice, and perhaps the unsanitary quarters, poor ventilation and sedentary life of the city resident combine to cause the fluctuations on the trophic centers and to inhibit the secretory functions, which terminate in habits of constipation. It is well known how often this effect is encountered in the country lad when he assumes the rôle of college student. Office employment, service in department stores, the mechanic's work and similar occupations requiring intensive effort are conducive to colon stasis, to be self-corrected or otherwise treated. We need only to observe the transforming power of army camp life to be convinced of the salutary effect on previously erratic organs of elimination. The pale-faced city clerk becomes, with his rural comrade, erect, robust and ruddy. I have on record several such cases cured by camp life.

A DIATHESIS

To direct our thought to the subnormal colon, without consideration of certain terminal effects on the economy, would be treating our subject like Ephraim's "unturned cake," half baked. That colonic atony appears to be antecedent to arthritism or at least concomitant with it seems well established. Some students in enterology, notably Axtell and Reed, profess to coordinate subnormal colon functioning with epilepsy, as cause and effect. The correlation of asthmatics and so-called neuro-arthritides in such conditions is well known. It must be conceded, also, that, while constipation is consonant with these ultimate phenomena, not all constipated persons manifest any of them.

These observations show that mucous colitis, either as cause or effect, is in close connection with the nervous system. Analysis of the following facts will demonstrate this more fully. A certain number suffer more or less from intense reflex disturbances going from the irritated intestine, by means of the bulb, thence by that of the pneumogastric nerve or the sympathetic system, and reverberating on the most diverse organs. The heart is subject to this reflex nervous action, with attacks of tachycardia after meals, then intermittences; and an irregularity of the heart's rhythm; and even attacks of pseudo angina pectoris are not infrequent. The proof that these nervous phenomena are correlated with the function of digestion is that they are usually terminated by a stercoraceous evacuation followed by relief.

The terminal threads of the vagus in the lungs are also apt to be affected in the same way. I have often seen marked attacks of asthma from this source. The patient suffocates for want of air, the windows are thrown open, the thorax is immobilized in the act of expiration, and inspirations are made with great difficulty.

In regard to the arthritides as an end-product of intestinal origin, there are undoubted cases, which is in agreement with the splendid researches of Rosenow.

Brick[1] says:

> It cannot be claimed that any specific organism is constantly associated with the disease. Some observers have

---

[1] Brick, J. C.: Tr. Am. Proc. Soc., 1912, p. 157.

found the joint fluids sterile, while others have isolated organisms. We may conclude, therefore, that the majority of cases contain no organisms either in the blood or joint fluids. The infection theory of its cause has many features which cannot be determined, such as glandular or splenic enlargement, which at least suggest the result of a toxemia from a distant point, possibly the gastro-intestinal tract. I am inclined to the view that the varied phenomena of arthritis deformans are due to a cerebrospinal toxemia, in other words a trophoneurosis of infective or toxic origin.

Physicians have relieved many cases of neuro-arthritism, by directing attention to a sluggish colon, restoring it to normal activity. This fact is proof that, in some cases at least, it is one focus of infection and becomes a diathesis or predisposition to disease in remote parts.

CONNECTION OF ACQUIRED EPILEPSY WITH COLITIS

There are a few advocates of the theory that acquired epilepsy or those attacks beginning late in life are a trophoneurosis of toxic origin from the colon. In these cases the patients are so easily impressed by the physician's efforts to help them, that he is often misled by their enthusiasm into thinking a permanent cure is at hand, to be doomed to disappointment. Yet permanent cures are reported by some, and much improvement is reported by others, due to keeping the colon clean. Axtell is a firm believer in the correlation of membranous colitis and epilepsy. The demonstration of certain toxemias of the convulsive and nonconvulsive type seems a forward step in the solution of this problem.

A patient under my care since 1912, a married woman, aged 47, who had had both grand mal and petit mal attacks at varied intervals for fifteen years, had acquired epilepsy. Twenty years previously, she had had an oophorectomy and appendectomy performed, which had been followed by severe intestinal stasis and colitis, and a few years later with the fits. The neurologist, with his usual remedies, had kept the attacks under control very well, but finally referred the case for treatment of the colon. We found obstinate constipation, glairy mucus, severe periodic cramps, and a large postoperative hernia. The hernia was repaired, at which operation were noted adhesions too extensive to break up, involving the ascending colon and the sigmoid. So with a hope of reducing the colitis to a minimum, and of thus possibly influencing favorably the epileptic seizure, we performed a cecostomy. She has used irrigations of various kinds through this opening during this time, and has had only three grand mal seizures in six years; but it is only fair to state that mild cataleptic spells of momentary duration have occurred rather frequently of late. For two years following the operation, she did not have a single spell. On the whole, she has had a comparatively good six years, when contrasted with the weekly and daily attacks previously recorded.

I am not prepared in this case to deduce any definite conclusions, but I believe that, if the extensive intestinal traumas could be corrected, the correction would go a long way toward clearing up this case permanently. I believe, also, that the case is a good illustration of the verity of the theory that the subnormal function of the colon is a diathesis leading to acquired epilepsy and other neurasthenic dyscrasias. I do not think that epilepsy in young people has this correlation of cause and effect. Yet it is well known how even they improve on intestinal ablutions.

CAUSES AND TREATMENT

When confronted by patients suffering from subnormal colon activity, we write in our case records such notes as: hemorrhoids, migraine, gravel, arthritism, very great nervousness, hereditary nervousness, hepatic lithiasis, gout, rheumatism, impressionability, obesity in the family, and tendency to worry.

To apprehend the essential and underlying cause of this array of symptoms will properly direct the treatment, both medical and surgical. The treatment cannot be considered in extenso, but merely suggested.

Diet is the first desideratum. All articles of food should be avoided whose digestion terminates in much residuum, and further irritates an already jaded colon. We may give milk, meat soups fat-free, porridge, barley, oatmeal, rice, arrowroot, etc.; eggs, boiled, scrambled or in custards; boiled fish, lean roast, and boiled mutton or beef, etc.; vegetables mashed fine, as potatoes, beans, peas and lettuce; but on no account green vegetables.

The time limit will not allow further discussion of diet and medical treatment of constipation. Suffice it to say that a daily evacuation should be secured by mild laxatives, for of the two evils choose the lesser.

How many persons there are who for years go to stool only by means of a daily laxative, and whose health is not worse, but on the contrary better, than that of those persons who, on pretext of not irritating the intestine, allow fermentable, noisome matter to accumulate there constantly! I would suggest liquid petrolatum (mineral oil) as a purgative and periodic morning doses of sodium phosphate in hot water. I would here emphasize the use of iodin to secure the best results in restoring an atonic colon swarming with bacteria. Solutions of half-grain doses of iodin with aromatic fluid extract of cascara sagrada in a palatable vehicle are well borne.

By means of the roentgen ray, structural deviations may be deciphered that will bring the case into a domain of surgical therapy. How many cases of subnormal colon are restored to normal activity by anorectal surgery, appendectomy, cholecystotomy, or intrapelvic adjustment! Ochsner has reported three cases of rheumatoid arthritis cured through an appendectomy which restored colonic function. The abdominal supporter has done good service in many cases of enteroptosis. Partial colectomy, or short circuiting, does not give me as good results as have been reported by other surgeons.

The pendulum is swinging toward more conservative measures in restoring the subnormal colon. Hammock fixations of displaced viscera should be rarely resorted to. Rather should we endeavor to restore the function by such remedies as strychnin and belladonna to their physiologic limit, together with such remedies as may be secured only by rural environment. Such measures as direct or indirect irrigation, with styptics like krameria, tannin, etc., or, if there is much inflammation, the use of oils, salines, etc., are beneficial. Direct irrigation with cecostomy is effective in severe cases. Finally, a complete survey of the treatment is not designed here, but rather a suggestive outline, with an admonition against drugging as a means of building up broken-down constitutions. Neurasthenics do better on such measures as rest, exercise, good air, proper diet and agreeable environment.

SUMMARY

1. The subnormal colon is a term we have used interchangeably with membranous colitis.

2. The cardinal symptoms are pain, constipation and mucus.

3. Factors to be considered that predispose to atony are enteroptosis, bacterial invasions, occupational environment and neurotic constitutions.

4. It is probably a diathesis toward arthritism, tachycardia, asthma, etc.

5. Further observation should be made in order to link it with acquired epilepsy.

6. Treatment should be comprehensive, each case being a separate problem, to be solved by dietetic, medical or surgical measures, or by all combined.

ABSTRACT OF DISCUSSION

Dr. Dwight Henderson Murray, Syracuse, N. Y.: I think the causes of these troubles that go on to autointoxication, convulsions and chronic nervous troubles are the result of neglect on the part of the profession in not instructing the mother how to care for the child, so that it will not be necessary to give laxatives. Another necessity that we neglect very much is the drinking of sufficient water. The system needs a certain amount of water for elimination, for building up the system and for metabolism. It is also important that one be regular with the the time for bowel movements. I tell my patients that absolute regularity is necessary, and that the proper time is the first thing in the morning. I direct them to sit on the toilet and make the effort, whether they have any desire or not; if this is not successful, I direct them to take an enema of plain water, while lying on the left side. I instruct them not to wait, because normal peristalsis will not take place unless the bowel is about full, and unloading the bowel at night defeats our natural morning action.

Dr. E. L. Eggleston, Battle Creek, Mich.: I believe that a greater number of our patients suffer from some form of colonic disturbance than from any other condition. So far we have not been able to determine definitely the toxic products resulting from bacterial activity in the intestine, although we believe from clinical evidence that specific products are elaborated. I can hardly agree with Dr. Beach that an atonic condition of the colon is frequently found. My observations lead me to believe that in subnormal colon we find a spastic condition in a large proportion of the cases. When there is severe constipation, the roentgen examination reveals a spastic condition of the distal colon with a dilated cecum, and especially do we find this condition to obtain in neurasthenia and other conditions where there is a disturbance of the vagosympathetic nervous mechanism. If you make inquiry of these patients as to how long it has been since they have had a formed bowel movement, they will tell you it has been weeks, or months, or sometimes years. This condition is practically always the result of a spastic condition of the colon, and an improvement in their condition is indicated by the passage of a normal formed stool. This has resulted, not from irritating the colon by cathartics, but from relieving the local congestion and by measures that tend to restore a normal nervous state. I believe that there are two conditions which are responsible for this spastic condition, one a local condition incident to the neglect on the part of the patient in properly caring for himself by allowing the intestinal contents to accumulate for an abnormal length of time, and the other a reflex nervous condition. Dilatation of the colon, particularly the cecum, is entirely the result of the spasm of the distal colon and the dilatation can be relieved only by measures that relieve the spastic condition of the pelvic and ileac portion of the colon. Rest, bland foods, heat externally, warm oil enema, and agar-agar and liquid petrolatum by mouth are measures that are well adapted for the relief of such conditions.

Dr. W. H. Stauffer, St. Louis: The factors involved in producing subnormal colon function are generally threefold: dietetic disturbances, adhesions resulting from surgical operations, generally of the uterus or adnexa, and the local conditions of the lower bowel produced by the use of cathartics and the improper use of enemas. One school of pediatricians teaches that children ought not to drink any water until they are a year old; that milk is the natural nourishment for the child, and it should have nothing else. Another class of pediatricians and nurses insists on giving children enemas in order to produce regularity of bowel movement. This practice should be condemned. I do not agree in regard to the use of preparations of petroleum. They do not empty the bowel. After continuous use of these preparations you will find a condition very much like that found in the automobile engine when it needs cleaning, and until that condition is corrected you will have no normal bowel function. The improper use of enemas causes undue distention, producing atony of the bowel. The occasional use of petroleum is all right, but the habit must not be formed.

Dr. Nathan Rosewater, Cleveland: I was probably the first to prescribe liquid petrolatum internally, fully twenty years ago, and I have prescribed many barrels of it since. It is neither saponifiable nor absorbed through the bowel wall, nor oxidizable; does not maintain germ life, but it acts as a protective and lubricant to the inflamed or traumatized mucosa, while it softens the feces, thus reducing flatulence. I have prescribed it for infants 2 weeks old, while for the aged it is valuable for relaxed as well as for the spastic bowel. It is not a cathartic. It does not stimulate peristalsis, but by its lubricant action permits the normal force of bowel peristalis to exert itself with little or no spasm or colic. It is as useful as a protective in diarrheal as in constipated states. I agree with Dr. Murray as to water, but give it methodically, as to proper time and quantity, to secure the proper amount to flush the circulation, as well as the bowel. It acts more as a bowel flush if two, three or four glasses, hot, warm or cold, are given fully an hour or two before breakfast, when the stomach is surely empty. The bowels then move usually before or soon after breakfast, when the increased peristaltic waves during and following the meal assist in driving the stool forward. In the severe cases the patient is given two meals a day. Two glasses of water hourly or half hourly are given until eight or ten glasses are taken. This flushes the bowel thoroughly, softens and removes hard scybala, whereby mucous colitis and other conditions resulting from fecal stasis and pressure are controlled. For infants and children a sufficient amount of water fully two or three hours after each feeding flushes the bowel and produces softer and less irritating feces and prepares the stomach for the next meal.

Dr. William M. Beach, Pittsburgh: I am heartily in accord with Dr. Murray on the use of water, but I have been in the habit of adding a little salt to the water. The advantage in giving salt water is that one drink makes the patient want another, and in that way he gets the amount of fluid which he ought to have. I want to recommend iodin, administered internally, to restore functional activity of the glands of the colon. I suggested iodin, in half-grain doses, in my paper.

Relation of Cancer to Economic Condition.—In an investigation of the relation of incidence of and mortality from cancer in the period 1914 to 1916, conducted by the statistical department of the Metropolitan Life Insurance Company, interesting conclusions were arrived at concerning the relation of cancer to the economic condition of the victim. The insurance company's policy holders are divided into what are called ordinary, intermediate and industrial classes, the economic condition of the ordinary class being best, intermediate next, and the industrial third. The study led to the following conclusions: the current opinion that there is a positive relation between poverty and a low cancer rate is in all probability unfounded; the cancer rate increases as we go down in the economic scale; this is true of both sexes and by age period where sufficient data are available to form conclusions. It is said that medical selection has been considered in arriving at the foregoing conclusions. Medical selection against cancer is most effective in the ordinary department, and is limited to the earlier ages and to the earlier years of issue. In both ordinary and intermediate departments the effect of medical selection against cancer is limited to the first and perhaps the second year of issue.

MUNICIPAL HEALTH ADMINISTRATION

GENERAL CONSIDERATIONS *

ERNEST C. LEVY, M.D.
NEW YORK

The total estimated population of continental United States in 1916 was 102,017,312. Of this population, 41,752,530 was urban, that is, was in communities having more than 8,000 inhabitants. There were 770 such municipalities.[1]

In other words, 40.9 per cent. of all our people have their health looked after (or not looked after, as the case may be) by 770 local health departments. In this single consideration, we see the great importance of municipal health administration and also, it would seem, its relative simplicity compared with the problem of looking after the health of the 59.1 per cent. of the rural population. The latter population, which is scattered over the rest of the country and reached only by a bewilderingly large number of local organizations, can at best be coordinated only by efficient state departments of health.

To discuss municipal health administration as a whole would be obviously unprofitable. Dealing with the cities by groups according to population, as has been done by the chairman, helps the situation. Unfortunately, the number of special papers in this symposium had to be limited to three. This necessitated the leaving out altogether of cities with more than 500,000 inhabitants and (more to be regretted) the making of groups with such wide limits of population as to render these groups far from homogeneous even in this single respect.

DISTRIBUTION OF URBAN POPULATION

Let us see how the urban population of the United States is distributed.

TABLE 1.—MUNICIPALITIES IN CONTINENTAL UNITED STATES, JULY 1, 1916

Group	Number in Group	Estimated Population
1,000,000 inhabitants and over	3	9,810,081
500,000 to 1,000,000 inhabitants	7	4,438,369
100,000 to 500,000 inhabitants	56	11,157,102
25,000 to 100,000 inhabitants	201	9,177,026
20,000 to 25,000 inhabitants	70	1,540,749
8,000 to 20,000 inhabitants	433	5,629,203
All over 8,000 inhabitants	770	41,752,530
Population continental U. S.	...	102,017,312

In Table 2 certain of the foregoing figures have been reduced to percentages. In this table only one group is made of places having from 20,000 to 100,000 inhabitants, so as to conform to the groups in the papers which are to follow.

TABLE 2.—PERCENTAGES OF POPULATION IN CITIES ABOVE 8,000, AND PERCENTAGES THAT EACH GROUP OF CITIES CONSTITUTES OF TOTAL NUMBER

Group	Percentage of Entire No.	Percentage of Population Urban	Percentage of Population Total
1,000,000 inhabitants and over	.4	23.5	9.6
500,000 to 1,000,000 inhabitants	.9	10.6	4.4
100,000 to 500,000 inhabitants	7.3	26.7	10.9
20,000 to 100,000 inhabitants	35.2	25.7	10.5
8,000 to 20,000 inhabitants	56.2	13.5	5.5
	100.0	100.0	40.9

Table 2 shows that two years ago (the latest year for which official estimates are available) 9.6 per cent. of the total population of continental United States (23.5 per cent. of the total urban population) was to be found in our three greatest cities, of more than 1,000,000, while 4.4 per cent. of the total population (10.6 per cent. of the urban population) was in the seven cities of between 500,000 and 1,000,000.

Thus our ten greatest cities, those with populations or more than half a million, contained 14.0 per cent. of our total population and 34.1 per cent. of our urban population.

These ten greatest cities, however, represent only 1.3 per cent. of the total number of municipalities in the United States. For this reason, and also because, in the carrying out of their complicated administrative functions, the health officials of these ten greatest cities would gain but little from any formal paper here presented, the section chairman and I were of the opinion that the small number of papers that could be read had better deal with health administration in cities of smaller size.

1. CITIES WITH POPULATION FROM 8,000 TO 20,000

The last of the groups given in the tables—that containing cities of from 8,000 to 20,000 inhabitants—is the most important of all from several points of view. It is important numerically, for it embraces 433 communities, or 56.2 per cent. of the 770.

Chiefly, however, does the importance of this group appeal to us because only very exceptionally will a community of less than 20,000 have a competent health officer. Yet 5,629,206 citizens of the United States live in communities of this size. Civic pride will ordinarily lead these places to have nominal boards of health of their own. Certainly they should have proper health protection in one form or another, since they have their own peculiar health problems quite distinct from those of the surrounding country. Hence it is that communities of this size present one of the most difficult problems in the entire field of public health administration.

In the United States, modern public health work had its first development in certain of our large cities. Next came efficient state health departments. More recently a number of cities of less imposing rank have begun to do excellent public health work. Still more recently we have found much time and attention devoted—and very properly so—to the subject of rural sanitation.

In consequence of the developments just referred to, it may safely be asserted that we have today in this country a far more satisfactory mass of information on public health administration for states and for cities of, say, over 25,000 inhabitants, on the one hand, and for rural sections, on the other hand, than we have for the intermediate communities, namely, those of less than 25,000 and particularly those of less than 10,000 or 15,000.

In various ways the attempt has been made to deal with the problem of health administration in these small communities. Inclusion as part of a really efficient county health department, special arrangements with the state department of health, the combination of several favorably located small communities under a single administration of their health affairs which is better than any one of them could individually afford—these are among the measures that have worked well in special cases.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] For all statistical data in this paper, I am indebted to Mr. C. S. Sloane, Geographer, United States Bureau of the Census.

The very difficulties of the small cities made it also difficult to find just the man to discuss their problems from the standpoint of actual experience. So we are fortunate in getting Dr. Armstrong to handle this subject. The Framingham situation is, of course, most exceptional. But Dr. Armstrong himself realizes this fully and may be relied on not to present the Framingham work as a thing which may be followed—certainly not as yet—in the ordinary small city.

2. CITIES WITH POPULATION FROM 20,000 TO 100,000

The group of cities containing from 20,000 to 100,000 inhabitants embraces 271 communities, or 35.2 per cent. of all the cities in the United States. Their aggregate population is 10,717,775, which means that 10.5 per cent. of the people of the United States and 25.7 per cent. of the urban population live in cities of this group.

In discussing health administration for this group of cities, Dr. Furstman has a difficult task, since, more than any other group as arranged for the purposes of this symposium, it embraces cities of widely different requirements at the two ends of the scale. It is, for example, open to question whether a city whose population slightly exceeds 20,000 should, as the practice of public health now stands, have a whole-time health officer. On the other hand, there can be no question that every city, long before its population reaches the 100,000 mark, should have a health officer who not only devotes his whole time to his public duties, but who is trained in sanitary science and who possesses considerable executive ability.

In many other particulars there is a wide difference between the requirements and the methods to be followed in the rather mixed class of cities which have been included in this single group. This difficulty will give Dr. Furstman full opportunity to exercise that ability which he has shown as health commissioner of La Crosse.

3. CITIES WITH POPULATION FROM 100,000 TO 500,000

The group of cities that have populations between 100,000 and 500,000 is numerically the smallest that will be considered in the papers of this symposium. It includes fifty-six municipalities, or only 7.3 per cent. of the 770. The aggregate population, on the other hand, is the greatest of all, being 11,157,102, which is 10.9 per cent. of the total population of continental United States and 26.7 per cent. of its urban population.

In spite of the fact that the margin of 400,000 between the upper and lower limit of population in this group is by far the largest that is found in any of the three groups covered by our papers, nevertheless this group is the most homogeneous of the three, by reason of the fundamental fact that every city in the group should have at the head of its department of health an officer equally expert in sanitary science and in the handling of men. After this basic requirement is satisfied, all else becomes merely a question of giving to the right man abundant financial and moral support and a free hand in the development of a department of health which, however much he may be helped by study of what has been done elsewhere, he must work out to suit the peculiar circumstances and needs of his own community.

Cities in this group should each have a real department of health, not merely a board of health with a chief executive officer who is required to be a sanitary jack of all trades, a condition almost necessary in smaller communities. With increasing insistence, as we go from the lower to the upper limit of population in this group of cities, the health officer should be relieved of detail work by surrounding himself with able men in each of the department's activities.

Health administration in this group of cities will be dealt with by Dr. Landis, whose work and accomplishments as health officer of Cincinnati entitle him to speak with real authority.

In the arrangement of this symposium on municipal health administration, we have sought to make it of a practical nature, in the hope that the papers that follow may be of real help to those who are now in control of city health departments or who may later be called to this important field of work.

HEALTH ADMINISTRATION IN CITIES OF LESS THAN TWENTY THOUSAND POPULATION*

D. B. ARMSTRONG, M.D., M.A., M.S.
Assistant Secretary, National Tuberculosis Association; Executive Officer, Framingham Community Health and Tuberculosis Demonstration
FRAMINGHAM, MASS.

The writer is not and never has been a health officer in charge of routine health administrative work in a small city. On the other hand, as executive officer for the Framingham Community Health and Tuberculosis Demonstration, it has been possible to consider the small city health problems, with the more or less unique advantages of the laboratory worker having for his field an urban community as a social laboratory. It is true that, with adequate funds for health work along various lines available in the demonstration budget, it may be considered that conditions are far from typical. Further, Framingham as a field for experience is under New England town government and in that way differs from similar communities in other parts of the United States in its form of official administration.

Because of the advantages, as well as the limitations inherent in this experience background, no attempt will be made herein to give an historical résumé of small city health conditions. An effort will be made to analyze with some thoroughness the health needs of communities of this kind and the author will endeavor, primarily on the basis of the Framingham experience, to suggest methods for meeting these needs.

While the object of this paper is to discuss in general the health needs of cities of this size, and not to describe in particular the Framingham activities, it may be wise to state that the experience in Framingham is being acquired in a reasonably average American community. Framingham now has a population of 18,000 people, of which more than 6,500 are directly engaged in industry. More than 27 per cent. are foreign born, and in the last five years the town has experienced a growth in population of 22 per cent. The industries are varied, and the social, racial, and economic conditions are typical of a normal industrial town.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

HEALTH STATISTICS OF SMALL CITIES

As a justification for giving consideration to the health needs of the smaller cities, it may be pointed out that, of the entire population of the United States, July 1, 1916, 7,629,128 individuals were resident in communities having a population of more than 8,000 and less than 25,000. A further analysis of the 1915 census shows that for the registration area, there were at that time 262 cities with a population of more than 10,000 and less than 25,000. The population, the total number of deaths, and the general death rate for special groups of these cities are indicated in Table 1.

TABLE 1.—POPULATION AND GENERAL DEATH RATE FOR TWO HUNDRED AND SIXTY-TWO CITIES IN REGISTRATION AREA BETWEEN TEN THOUSAND AND TWENTY-FIVE THOUSAND

City Groups	Population	Total Deaths	General Death Rate
All cities	4,251,823	60,104	14.1
New England cities	851,136	11,589	13.6
Massachusetts cities	449,958	5,582	12.4
N. E. without Mass. cities	401,178	6,007	15.0
All cities outside New England	3,400,687	48,515	14.3

From this table it will be noted that cities of this class have a reasonably good general death rate (14.1). Massachusetts cities have considerably better than the average rate (12.4), while New England without Massachusetts has slightly more than the average (15.0). It may be interesting to point out that in 1915, Framingham, with 13,815 people and 242 deaths (residents and nonresidents, without stillbirths) had a general death rate of 17.5. This rate corrected for nonresidents was for that year 13.5. For the decade from 1906 to 1916, the general death rate including nonresidents was 15.3 for Framingham. In 1917 this rate was 15.1 (11.1 when nonresidents are excluded).

Another reasonably reliable criterion of health conditions in any community is the situation in regard to tuberculosis mortality. Consequently, an effort has been made on a similar scale to ascertain the mortality of tuberculosis for cities of the smaller size. The 1915 census has been used as a basis here also, and the rates cover all forms of tuberculosis.

TABLE 2.—DEATH RATES FROM TUBERCULOSIS IN ONE HUNDRED AND SEVEN TOWNS

Rates per Hundred Thousand	Cities Falling in Corresponding Rate Class
31 to 60	10
61 to 90	23
91 to 120	22
121 to 150	15
151 to 180	12
181 to 210	12
211 to 310	11
311 to 410	2

For the registration area as a whole in 1915, with a population of 67,336,992 (67 per cent. of the total population of the United States), there were 98,194 deaths certified as tuberculosis, giving a death rate of 145.8 per hundred thousand. In comparing conditions in smaller cities with the registration area as a whole, I have selected five towns in each registration state with a population of more than 10,000 and less than 25,000, except when the states had fewer than five cities of this size. Institution towns, with corresponding above average rates have not been included. This selection gave 107 towns in all, twenty-five of which were in New England. The distribution of all these towns according to tuberculosis rates is set forth in Table 2.

It will be noted that the majority of these cities show tuberculosis rates of less than the average for the registration area. For the most part, cities with higher rates are from southern territories with large colored populations.

Tuberculosis rates in the twenty-five New England cities are distributed according to the figures set forth in Table 3.

TABLE 3.—TUBERCULOSIS RATES IN TWENTY-FIVE NEW ENGLAND CITIES

Rates per Hundred Thousand	Cities Falling in Corresponding Rate Class
51 to 80	6
81 to 110	7
111 to 140	1
141 to 170	6
171 to 200	3
201 to 250	2

It will be noted that approximately half these cities fall below the registration area rate. For any single town, the rates show wide fluctuations yearly, because of the small population involved. In 1915, for instance, Framingham had an exceptionally low rate, 65.1. For the decade 1906 to 1916, the average rate was 99. On the other hand, a study of the reliability of death certification in Framingham indicated that the more probable tuberculosis mortality would be represented by a rate 22 per cent. more than the stated rate. For Framingham, this would give for the decade a rate of 121.5 per hundred thousand, and for the year 1915 a rate of 90.7 per hundred thousand. On the other hand, it is safe to assume that approximately this same error would be found in other communities.

ROUTINE HEALTH PROBLEMS OF CITIES

To return to the direct consideration of the small city health problems, it is obvious that in many respects the factors involved are similar to those met with in the larger municipalities. The routine health problems which cities of all sizes have in common may be briefly indicated as follows:

1. General sanitation. Those responsible for health administration have to deal with matters of general sanitation, such as water supply, milk and food control, sewage disposal, mosquito and fly suppression, regulation of stables, privies, wells, etc.

2. Communicable disease. The health officer is concerned with the control of contagious disease, the suppression of typhoid fever, tuberculosis, etc., and the provision of laboratory facilities for the carrying out of diagnostic and therapeutic measures.

3. Infant life. The provisions for adequate supervisory and educational activities along prenatal, obstetric, and postnatal lines, reaching into the preschool period are essential in the care of infants, and include nursing, clinics and social efforts.

4. School life. The needs of small and large towns alike involve the provision of medical, clinic, and nursing service among schoolchildren.

5. Industrial life. The industrial workers everywhere, regardless of community size, should have provided for them, from public or private resources, adequate medical, nursing, dispensary, first aid, and social service facilities.

6. The middle age. The problems of adult hygiene and of the control of degenerative diseases are the same everywhere, and may be met in small cities as well as in larger communities by the institution of hygienic, educational, and life extension procedures.

DIFFERENCES BETWEEN LARGE AND SMALL COMMUNITIES

Of greater interest than the similarity in problems are the differences that characterize the smaller communities in regard to their hygienic problems. In addition to specific and obvious differences, significant, yet intangible, factors of personality enter into the small town problem, making health administration there sometimes more direct and yet again more difficult.

1. In the first place, the relation of the health administrator to the practicing physician is of necessity more intimate and direct. His contacts are more frequent and more personal. A larger percentage of the population receiving medical care is in the hands of private physicians. Dispensary with outpatient service is less developed, the practice of medicine is less depersonalized. The official town agent, whether tuberculosis nurse or infant welfare nurse, etc., will find herself more frequently dealing with the family physician, and for that reason adaptability, tact, and tolerance are, if anything, more necessary in the smaller community than in the larger.

2. The development of group, "wholesale," or dispensary therapeutic services is less apt to be found in the smaller community and more difficult to establish, for medical as well as for economic reasons.

3. The atmosphere of intimacy which characterizes the relationship between the health administrator and the average citizen must seriously modify the type of educational work that can be carried on in the small community. The health officer, even in addressing the foreign-born and foreign-speaking people in his community, is appealing, not to an impersonal mass of humanity, but to his neighbors whom he meets daily on the street, in the stores, at church, at town meetings, etc.

4. Contrary to what one at first thought might suppose, an inferior degree of cohesion is characteristic of the smaller towns, particularly the New England towns, which more nearly coincide with townships in other sections of the country, and which are spread out over wider territories, frequently being composed of numerous villages, each with a greater or lesser degree of autonomy. Separate neighborhoods, sometimes of special races, are frequently isolated; hygienic conditions in regard to fundamental necessities, such as water supply and sewage disposal, frequently vary tremendously within the limits of the municipality; factories are of diverse types; the milk supply is most heterogeneous, etc.

5. In communities with a relatively small population, age, sex, and race factors may vary radically from average conditions found in larger and more representative units.

6. Many towns, particularly in New England, comprise in their limits a fringe of rural life, presenting special problems of farm hygiene.

7. Hospital facilities, of course, vary for each community, though presumably for most small towns they are less adequate, not only in regard to beds, but also in regard to special and oftentimes even routine medical service, than they are in the larger cities. On the other hand, a smaller community which is the trading and population center for a large semi-urban or rural district, may not only have excellent hospital facilities, but because it is the hospital center for a large population outside the community's own limits, it may have its morbidity and mortality rates seriously affected, unless corrections are made for nonresident illnesses and deaths.

8. All American communities are intolerant of so-called expert services. This is one of the fundamental defects which American democracy must remedy. The man specially trained for any piece of work is still ill-received by the average American community, and has not successfully been made a part of the community life. The recent vicious political attack on the health administration in New York City has met with indifference, if not support, by the rank and file of New York City citizens, largely because the municipality is reacting against the specialist service preeminently characteristic of the previous administration. This is true, of course, along other lines than health. Further, the same difficulty is, if anything, augmented in the smaller American community, for there more than in the larger cities, the citizens, expressing themselves through town meeting, or other local municipal organization, indulge themselves in a belief in the myth of early Grecian democracy, that each individual, be he only a "free man," is capable of governing in any capacity whatsoever, without regard to special training or modern technical requirements.

HEALTH MACHINERY

In discussing the machinery which ought to be provided in order to meet effectively the health needs of the smaller community, no attention will be paid to the cooperative plans that have been developed where small towns adjacent to one another have administered their health work in common. It is assumed that consideration needs to be given to an isolated or at least an independent autonomous community needing and capable of supporting an adequate health machinery of its own. It is the intention of the writer to give primary consideration to routine health machinery, first from the point of view of public provision, and second, through the machinery which private agencies in the normal community might, for the time at least, be expected to provide. Further, there will be discussed certain special health measures which are being experimented with in Framingham, and which, if demonstrated to be a success, may eventually be incorporated, in this community at least, into the routine machinery, and which may subsequently, as a result of this demonstration, be considered routine necessities.

ROUTINE HEALTH MACHINERY

A. Public Provision: 1. Board of health work. It is safe to assume that the health work of a community of 20,000 cannot be administered effectively on a part-time basis. The needs of such a community, as outlined earlier, indicate that full-time service must be required. Further, the Framingham experience has demonstrated that even a conservative New England community may be encouraged to appropriate sufficient funds to make full-time, reasonably adequate service possible. In order to meet the medical, sanitary, laboratory, nursing, and office necessities of a community of this size, the following staff is required: a medical officer of health, a sanitarian (laboratory worker), a tuberculosis nurse, an infant welfare nurse, and a secretary (stenographer). Further equipment includes two or more infant welfare clinics and a small laboratory.

2. School health work. In some communities the school health work may be administered by the board of health, and in others by the school committee. It is probable that an economy in administration will result in having the school health work handled by the board of health staff. In either case, however, the following staff is necessary for a community of this size: one full-time physician, two school nurses, a part-time dentist, and a physical director. Additional equipment will include a dental clinic, an eye refraction clinic, a nose and throat clinic, several open-air classes, provision for school lunches, etc.

B. Private Provision: 1. Hospital facilities. In addition to whatever routine private hospital facilities the community may possess, arrangements should be made for the local isolation of communicable disease, an outpatient service on a pay, self-supporting basis, a sun room and perhaps other facilities for the nonpulmonary cases of tuberculosis, district nursing work, etc. There are practical advantages in having the local district nursing work administered from the hospital, particularly if the hospital operates a nurses' training school; for the nurses in training, under adequate supervision, may be used in the district work.

2. Industrial medical service. Full-time medical, nursing, clinic, and first-aid facilities should be provided at the expense of the industries, for convenient units of the industrial population. This work in the industries may for the most part be largely diagnostic, the therapeutic service being provided by private physicians, and by the outpatient pay clinic mentioned above. Single industries are not large enough to afford full-time service, medical and nursing provision may be made on a joint basis, several industries, preferably similar in type, combining to purchase this service.

3. Private civic provision. Through the creation of a community-wide civic association, essential health activities may be established on a basis of private resources. This provision should meet the needs of recreation, relief, public health education, social organization for health, athletics, and life extension work. The staff necessary for this work will include a social worker, an athletic director, a stenographer, and possibly a special investigator.

SPECIAL HEALTH MACHINERY

In addition to these routine activities, certain experimental activities have been created or are being created in the Framingham "health laboratory." Most of the services to be discussed under this head are distinctly experimental in character, as their usefulness and self-supporting qualities must be established before their recommendation for adoption to the community will be considered as justified. If it can be demonstrated that they meet recognized community needs, some of them would eventually become a part of the town's official health work; others would be taken up by private agencies. These services might be briefly discussed as follows:

1. Industrial Medical Service for the Smaller Industries: It is hoped that a few of the smaller industries in Framingham, not yet provided with full-time medical and nursing service, may be persuaded to cooperate with each other in the purchase of this service. If sufficient appropriations are made to cover the salary of full-time physicians and nurses, there is no reason why this work might not eventually be absorbed by the community and supervised by the local health authorities. Presumably, also, the similar services already established in the larger industries will be coordinated with the service to be established in the smaller plants, and will be supervised by the same central authority, at no expense to the town itself.

2. A Central Milk Pasteurization Plant: In order to encourage the pasteurization of milk, and to make this measure possible for the smaller producers in this community, a central plant for the collection, pasteurization, and distribution of milk is proposed. Once established, this also should be operated on a self-supporting basis, and might be supervised by the local health authorities.

3. An Outpatient Medical Service: With the diagnostic work which is now being carried out in the schools, factories, infant clinics, and elsewhere, the need of facilities for treatment is emphasized. On the other hand, it is believed that these facilities should be established on a self-supporting basis, local medical service should be employed, and adequate compensation should be offered to the physicians engaged for this work. Presumably this work should be carried out in cooperation with the local hospitals, though its coordination and supervision might be directly under the local medical officer of health.

4. An Expert Medical Consultation Service: This service, already in operation for more than a year in Framingham under the auspices of the demonstration, has proved its worth, not only in the detection of tuberculosis, but also in the diagnosis of other conditions. Such a service would seem a necessity for any community, regardless of size, but particularly for smaller communities, where expert facilities are more frequently lacking. There is no reason why this service should not eventually be, in part at least, self-supporting, and its ultimate sponsors might be the local hospitals, the local health authorities, or the local medical organization.

5. Medical Examination or Life Extension Work: Already in Framingham, more than 5,000, or nearly one third of the population, have been examined, largely by physicians from out of town. The citizens are in increasing numbers calling on the local physicians for routine health examination work. This practice of annual medical inspection for the adult population outside the schools and factories should be extended and placed, if possible, on a permanent basis. Its ultimate supervision might be located in the official or private agencies mentioned previously.

6. Community Houses: Already there have been established, under the auspices of the school committee and the local industries, two community houses in Framingham. The programs for these civic centers include a large amount of health work along educational and organization lines. These agencies, while not directly self-supporting, are already established under local auspices and should perhaps be extended into other neighborhoods of the community.

7. A Summer Camp for Children: Such a camp, providing fresh air, recreation, food, and educational supervision for many children of the school and preschool age in the community, should become a permanent factor in the hygienic life of the town. While it cannot perhaps be made self-supporting, the per capita cost is small, particularly if operated as a day camp, and the results would justify public or private agencies in devoting sufficient funds to this work.

8. Neighborhood Health Committees: These have already been established in all parts of Framingham, and the expense involved in the maintenance of this intimate, neighborhood, social organization for disease detection and health promotion is extremely slight, other than the necessary supervision, which might eventually be given by a full-time worker employed by the local civic organization.

COST OF COMMUNITY HEALTH ORGANIZATION

The cost of an adequate community organization for health, as outlined in the foregoing discussion is, of course, the determining factor in its practicability. At the present time communities of this size are spending on an average of not more than 20 or 30 cents per capita on health work, from both private and public sources. Framingham, when chosen for the demonstration, was spending about 40 cents per capita. It is now spending from the public funds approximately 82 cents per capita, which compares very favorably with any community in the United States, regardless of size. Framingham is doing this without, in any way, being conscious of undue public financial burden. In addition, private agencies, including industries, are now spending nearly $1 per capita on medical and health service.

In considering the cost of adequate health machinery to the average community, attention will be paid only to the routine procedures previously outlined. These will be considered in groups corresponding to the services previously outlined.

A. *Expenditures for Public Facilities.*—1. The board of health. An adequate budget for a local board of health should total approximately $12,000, distributed as follows: medical officer of health, $2,500; sanitarian, $1,600; tuberculosis and infant welfare nurses, $2,400; secretary, $800; miscellaneous (including communicable disease work, dispensary work, laboratory work, transportation, office maintenance, etc.), $4,700.

2. The school health work. An adequate school budget ought not to exceed $6,000, distributed as follows: full-time physician, $2,500; school nurses, $2,200; part-time dentist, $500; clinic expense, $800.

This would give from public funds a total of $18,000, or approximately $1 per capita. In most communities a considerable saving, as far as public health expenditures are concerned, could be realized by the elimination from the health budget of certain items having no bearing on the morbidity or mortality rates. In Framingham, for instance, the board of health expenditures now include items totaling more than $1,500, made up approximately as follows: garbage collection, $625; plumbing inspector, $600; removal of dead animals, $30; slaughtering, $300. Practically all these activities might preferably be met by appropriations in other departments, thereby decreasing the burden which health work now carries, though obviously not decreasing the total town appropriations.

B. *Expenditure for Private Health Activities.*—1. In order to provide medical, nursing and other health machinery for the industrial workers in a typical manufacturing community of the size under consideration, it is estimated, on a basis of the Framingham experience, that the annual expenditures will amount approximately to $18,000 a year. This will provide at least three full-time physicians, several nurses, and clinic maintenance.

2. Civic activities. An annual budget of $4,000 for a civic association might be distributed as follows: secretary and investigator, $1,500; physical director, $1,200; stenographer, $800; miscellaneous, $500. On the other hand, many of the activities which might be undertaken, such as gymnasium class work, will prove in part self-supporting.

The entire expenditure necessary to meet the private health needs, including the needs of industry, ought not to amount to more than $20,000 to $22,000, or a little more than $1 per capita. On this basis, the entire community health expenditures from public and private sources would amount approximately to $2 per capita.

PRACTICAL RESULTS IN FRAMINGHAM

It is hoped that the unusual opportunities and resources now available from outside sources in Framingham will throw light on the value, not only of routine procedures, but of the special measures there being tried out. On a basis of the work there, many activities falling both in the routine and special categories may eventually be discarded or permanently adopted. Of course, in Framingham, the main object of the work is to discover and eliminate tuberculosis. On the other hand, as has been indicated in the foregoing paper, every opportunity is being seized to stimulate action along allied lines, and to develop a community-wide machinery for detection of disease and creation of health.

The work in Framingham was initiated shortly before Jan. 1, 1917, and was in part well under way during a fraction of that year. A summary of the mortality findings for 1917 in Framingham may be of interest, as indicating the conditions under which the demonstration was working, and the statistical basis with which its subsequent results will have to be compared. The situation in regard to mortality, as indicated for 1917, is not offered as a manifestation of the effect of the demonstration program. All that can be said at the present time is that it indicates a tendency, which, being in the direction of lower rates, must be maintained and if possible accelerated, if the measures now being tested are to prove of worth.

In Framingham, during the decade from 1906 to 1916, the general death rate including nonresidents was 15.3 per thousand. In 1917 it was 15.1. When nonresidents are excluded, the general death rate for this decade was 13.65, and for 1917, it was 11.1. The tuberculosis death rate per hundred thousand, corrected for nonresidents and death certification errors, was 121.5 for the preceding decade, and 99.0 for 1917. While infant mortality rates for the decade are unreliable, because of the inadequate birth registration, the infant death rate per thousand born in 1916 was 81, and for 1917, 73.

Thus far in Framingham, as has been adequately illustrated in the preceding discussion, the community, both publicly and privately, has been most generous in its support and in its endeavor to meet its own health obligations. The committee in charge of the work in Framingham are encouraged to believe that communities elsewhere, having this example, will endeavor to provide measures for health. Framingham is attempting to set these standards. Thus the nation's municipal health experimental laboratory may also become the nation's health town.

PUBLIC HEALTH ADMINISTRATION IN CITIES OF FROM TWENTY THOUSAND TO ONE HUNDRED THOUSAND *

J. M. FURSTMAN, M.D.
Commissioner of Health
LA CROSSE, WIS.

From the title of this paper you will undoubtedly realize that it is quite difficult to lay out a plan of health work that will be suitable for all. The question thus arises, why should this task be difficult? Should not health work be the same in a city of 20,000 as it is in a city of 100,000 or more, only somewhat modified to meet local conditions?

You have undoubtedly tried to compare the work of various health departments from annual reports issued by them and found it next to impossible to do so. The greatest single need is probably standardization. In other words, there appears to be no standard of measurement. The public health official realizes that such standardization will promote a unification of thought and action, which will make it possible for him to devise ways and means of fairly competing in the field of public health endeavor.

There is no question that every one engaged in public health work is trying to do what he thinks will accomplish the best results. But is he doing it? Have we as health officers, in the administration of our duties, kept pace with the advancement in public health work? Have we seen to it that the laws relative to public health work have been changed to conform with modern ideas, or are most of us still endeavoring to work under the ancient laws that were passed when contagious diseases were looked on as something mysterious?

Are we as health officers getting the best results for the money that is being spent on health work? It is my opinion that most of us are not. And why not? For the simple reason that we are not all working along the same lines. There is no definite standard laid out for health workers to follow.

In a questionnaire sent out to a number of cities ranging in size from 20,000 to 100,000, I found that considerable attention is spent, and money as well, on garbage collection and sanitary inspection, the latter including the inspection of alleys, outhouses, yards and foods, but little or no money is spent on laboratory facilities, medical inspection of schools and infant welfare work. As a matter of fact, most of the work done in the smaller cities consists in quarantining and fumigating for contagious diseases, in looking up nuisances and collecting garbage. The last branch of the work receives the bulk of the appropriation.

If the merchant or manufacturer hopes to succeed against competition, he must by good accounting learn which goods yield the highest profit. So the health officer, if he wishes his department to have its due share of the municipal budget, must learn which line of work yields the most for the sum expended. He should seek greater financial assistance for the most effective work and should eliminate, cut down, or at least not emphasize, those functions which yield little return for the money. It is difficult to change the direction of sanitary endeavor, but certainly it is our duty at frequent intervals to take account of stock and try thereby to discover the most profitable lines. It is also our duty clearly to set forth our conclusions, even though it may not be easy to convert the public, and particularly town and city councils, to new points of view.

ADVANCEMENT IN PUBLIC HEALTH WORK

There has been considerable advancement in public health work within the last fifteen years, and as we learn more about the causes of the various diseases, our methods of control change.

Years ago when a typhoid fever epidemic presented itself in a community, general orders would be issued to whitewash basements, yards would be cleaned, plumbing would be overhauled, etc., but the epidemic continued just the same because little was then known of the four great public routes of infection, namely, water, milk, food and flies, and what is still more important, carriers and missed cases.

When diphtheria broke out in school, the school would be closed for a few days, the building would be fumigated and the children would be permitted to return to school, but the diphtheria continued. Why? Because no laboratory facilities were at hand to detect the carriers.

In the past we have paid altogether too much attention to the environment and too little to the individual in the spread of contagious diseases. Most men engaged in public health work today are of the belief that contagious diseases are spread by the fresh discharges of the individual and that fomites play no part in the spread unless they are infected with fresh discharges. If this theory is correct, then we must educate the public to understand that fact. The sooner this is done, the sooner will men engaged in public health work be able to spend their appropriations for the more important phases of health work and thereby accomplish the most for the money expended.

DUTIES OF A HEALTH DEPARTMENT

In enumerating the administrative work of a health department, I am going to emphasize what seems the most important duties for the department to undertake.

First, the head of the health department should be a physician, who is especially trained in sanitation and hygiene. It should be his duty to teach the public about the preservation of health and the prevention of disease. The medical graduate of the past has not had this training, because of the limited amount of instruction in sanitation and hygiene that the schools then offered.

In the past the study of medicine has based its teachings on the old principle of the cure of disease, and still continues to do so; while the new profession of medicine, the one we hope for, will certainly have to recast some of the methods of the old medicine, so that it will emphasize the prevention of disease.

If the head of the department is fully qualified to undertake the work, he should be given full authority to choose his subordinates and lay out the work, taking up such activities as he knows will bring the best results for the money available. It is absolutely essential that the department be divorced from politics and that the terms of office of the head be made secure. In La Crosse a board consisting of three members is appointed by the mayor, each member

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

serving three years. This board has full control of the health department and is out of politics. The head of the department is appointed by this board and is responsible to them only.

The following activities should be undertaken: (1) control of contagious diseases; (2) medical inspection of schools; (3) infant welfare work; (4) laboratory diagnosis; (5) sanitation; (6) vital statistics, and (7) publicity and education.

CONTROL OF COMMUNICABLE DISEASES

The control of communicable diseases is one of the most important factors in public health work. In order to establish control, the health department must have the full cooperation of the local physicians, for without the knowledge of the existence of these diseases the department would be just as useless as the fire department would be without the knowledge of where the fire was. A thorough investigation of epidemics as well as sporadic cases must be instituted, in order that we may get at the source of the trouble and check the epidemic before it goes too far.

The epidemiologist must always keep in mind the four great public routes of infection, namely, water, milk, food and flies, and since epidemics are the exception to the rule, in the handling of sporadic cases, which he will be confronted with most of the time, he must never lose sight of the mild, the missed and the carrier cases.

Antitoxin and vaccine should be furnished free to all by the department and people should be urged to make use of them. A program should be instituted for the prevention of venereal diseases and tuberculosis.

In the treatment of tuberculosis, the use of the county sanatorium has been and is being urged all over the country.

There is no doubt that tuberculosis sanatoriums do considerable good but I question if we are getting enough good out of the money we are spending for them.

I am firmly of the opinion that if the same amount of money were used in the employment of visiting nurses, who would see tuberculous patients at home and educate them how to care for themselves properly, a great deal more would be accomplished, especially since we, in most instances, get only the patients with fairly advanced cases into the institutions. The nurses, while doing their work in the homes, would be in a position to watch all other members in the family and thereby detect the early cases. If we are going to build institutions for the prevention of tuberculosis let us build preventoriums to take care of the overwhelming number of patients who have been exposed by those that are sent to sanatoriums and really constitute only a small percentage of the cases.

The question in my mind is, are we really handling tuberculosis properly with the county institution and are we progressing in the control of this disease as spent and yields big returns.

MEDICAL INSPECTION OF SCHOOLS

Medical inspection of schools is no longer in the experimental stage. We know positively that any amount of money spent along that direction is well spent and yields big returns.

Medical inspection of schools should include not only the control of contagious diseases but also the routine inspection for physical defects, which is far more important, provided the children showing defects are followed up and the defects corrected.

In this great work, the visiting nurse makes her appearance and I wish to say that without her 90 per cent. of the value of school inspection would be lost. It is through the nurse's efforts in the home that we are able to get the results we are getting in school work. Medical inspection of schools should be under the supervision of the health department, rather than under the board of education. School boards have no authority, by precedence or by law, as have health departments, to follow back to its home outside the schools the ramification of the infection, of which the infected child in the school constitutes but one link. School boards also have no authority over nor information about the large number of children who are not of school age, nor concerning any adult, except those directly connected with the schools.

INFANT WELFARE WORK

This departmental activity surely needs no introduction. It has done and is doing more in health department work than any other activity. I am making this positive assertion because it is one of the activities in health work which, as we know by actual figures, is getting results.

Here again the nurse steps in, and without her we should be at sea. It was thought that clean milk and milk stations were the essential factors in reducing the infant death rate, but we really didn't begin to get results until the nurse was installed.

In this great work we must not lose sight of prenatal work nor of supervision of midwives and boardinghouses for infants.

In spite of the fact that every city undertaking infant welfare work has accomplished results in direct proportion to the amount of money it was willing to spend, it is surprising that many cities are spending considerable money for garbage collection, but not a dollar for this important activity.

LABORATORY DIAGNOSIS

A health department without laboratory facilities is about as efficient as a fire department would be without modern fire apparatus or an efficient water supply. A city, no matter how small, should have laboratory facilities, in order that the physician may be aided in making correct diagnosis and in that way be instrumental in lessening the number of contagious diseases. Examinations should be made for tuberculosis, typhoid, diphtheria and venereal diseases, and water and milk should be examined. The physicians should be encouraged at all times to make use of the laboratory. A laboratory in a community encourages more scientific work among physicians and consequently raises the standard in the community.

SANITATION

I am very sorry to say that sanitation as a phase of health work has been the most popular and one that is probably bringing us the least results for the money spent. With the old ideas as to the spread of contagious diseases we can readily see why this has been so popular. But since most of us know better, why don't we change our methods? Most of us know that we are not saving any lives through the removal of garbage and that this activity should be taken out of health work, but we still continue to attend to it because the public demands that we take care of it. A great deal of money is being spent on food inspection, while little or nothing is being done to see whether the people that are handling the food are suffering from tuberculosis, venereal disease or other contagious diseases.

I do not want to infer that there is no good accomplished from proper sanitation, but I do think we have been giving altogether too much credit to this work. We all appreciate that it is esssential to have a good water supply and that we must look after the milk supply, and in connection with the latter I wish to say that a great deal more time should be given the product on the dairy and less time spent in the chemical analysis of it.

Sanitation, as far as human excreta is concerned, is very essential and obtains results, therefore it is necessary that we have proper sewage disposal, and in smaller communities where there are no public sewers, especial attention should be given privies, because they are a direct menace to health. If they must remain, because of lack of sewers, they should be made as clean and flyless as possible.

VITAL STATISTICS

Without vital statistics, health departments would be at a loss to measure the progress made. Vital statistics are just as important to a health department as is the most careful accounting maintained by our most successful business enterprises. It is the bookkeeping of the health department, and unless the statistics are accurately kept, they are of little or no value to us at all.

PUBLICITY AND EDUCATION

It is within the scope of publicity and education that the success of public health work lies. We have been progressing rapidly in public health work, but we have failed to keep the public informed of our progress. It was not until the public health nurse was added to the department that we were able to get the results we are getting in the reduction of infant mortality, and why? Because she went into the home, gained the confidence of the mother and then educated her in the proper handling, care and feeding of her baby. The public must be educated in health work. They must be shown that it is no longer a mystery. The facts must be put before them, and I am satisfied if this is done that health departments will not have the trouble they now have in getting sufficient appropriations for carrying on this important work.

How are we going to educate the public? By means of publicity, motion pictures, talks, little mother's classes and, most important of all, by means of the school teacher and the visiting nurse. The addition to the department of a paid publicity agent, who is well versed in health matters, and who could place the subject before the public so that the ordinary layman could understand it, would be money well spent.

CONCLUSION

I wish to bring out these facts:

1. We are badly in need of proper standardization of public health work and it is my belief that the best way to go about this is through the creation of a national department of health that would set a uniform standard of work for all health workers.

2. We must take an accounting of the work we are doing to see if we are getting enough results for the money we are spending and to see if we are spending it in the right direction.

3. If the health department is to get the best results, it must be divorced from politics.

4. If the public is properly educated in public health work and is kept informed as to the progress we are making, there will be little difficulty in our obtaining adequate appropriations for the work; and there will be less difficulty in health departments' divorcing themselves from duties they know are not bringing results.

5. If the several branches enumerated cannot be taken up individually, I should suggest the following combinations: (1) control of contagious diseases, medical inspection and nursing; (2) food inspection and laboratory diagnosis; (3) vital statistics, and (4) sanitation.

6. Appropriations, instead of being made in lump sums, should be divided and the amount for each activity specified.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LEVY, ARMSTRONG AND FURSTMAN

Dr. John Dill Robertson, Chicago, said that there is not much difference between the health administration of a small community and a large one, because the latter is made up of a group of small communities. The cost per capita depends entirely on what is done. Is antitoxin given free to schoolchildren in case of a diphtheria epidemic? Is every case to be hospitalized? If so, then a contagious disease hospital is a necessity. By doing these things, he said, $5 per capita a year is not too much.

The health department is in reality a disease department. Money has been spent in fighting disease, rather than in preventing it. In Chicago about fifty cases of venereal diseases are reported each day. A venereal disease hospital has been opened to take care of that situation. About 2 to 4 per cent. of Chicago's population is tuberculous. A million a year, or 40 cents per capita, is spent in Chicago for tuberculosis work.

Mr. Eugene R. Kelley, Boston, said that we are apt to regard county sanatoriums and hospitals as if they were addenda, whereas they are supplements. We cannot do without one or the other. Massachusetts, he said, has come nearer to supplying proper supervision through the public health nurse to all classes of population than any other city. A mandatory law requires that each community of 10,000 or more inhabitants should maintain a tuberculosis dispensary. The main part of the dispensary machinery should be the visiting nurse. The affected communities cover 85 per cent. of the whole population. The state is divided into eight health districts. One health nurse and one doctor correlate the work of the dispensary and look after the regular cases. The follow-up work of the State Sanatorium for Consumptives is also being done by these workers. About ninety of the Visiting Nurses' Association follow up tuberculous cases in addition to the bed tuberculous. The biggest obstacle that those nurses have, Mr. Kelley said, is the lack of suitable institutions and beds. After developing a state sanatorium, a number of institutions for county cases of tuberculosis were created. However, the nurse is as essential as the institution. The completely rounded-out program, in Mr. Kelley's opinion, would be to have the nurse working in the home, getting the patients into the institution and supervising them after they come back; the institution taking the cases that cannot be properly handled in the home.

Dr. Herbert L. Wright, Kenosha, Wis., said that Kenosha will complete an isolation hospital soon. A health and dental clinic has been established; also a baby camp on an island in the lake, and a laboratory known as the State Cooperative Laboratory.

Publicity, Dr. Wright said, plays a very large part in the progress of health work. The public should be educated in regard to health activities. The people must see something. The baby camp and the dental clinic are tangible activities. Vital statistics also play a very large part.

Dr. Herman N. Bundesen, Chicago, said that in Chicago all cases of tuberculosis are visited. If the patient does not take reasonable precaution, he is reinstructed. If after several investigations, the patient does not adhere to the rules, the authorities placard the premises for five days. If this does not bring results, the patient is hospitalized. Usually, after from five to six weeks, the patient asks to go home. If conditions at home are safe, he is discharged. If he is an open case, he is visited at least once a week, and if he is slipping on the instructions, he will again be hospitalized.

Dr. Bundesen said that the idea of the visiting nurses is impossible, impracticable. They have no authority. The health department has the authority. The sanatorium or visiting nurse cannot get the cooperation of the patient. The health department can handle the case. With authority, tuberculosis can be controlled like any other communicable disease.

Dr. P. S. Schenck, Norfolk, Va., said that when Virginia passed some new child labor laws, two years ago, the health department was besieged with applications for birth certificates, about one in four or five of which could be supplied. In order to improve birth registration the King's Daughters were interested in this proposition. A force of 600 women was organized. The city was divided into districts, with about twenty workers in each district. Every house in the city was visited and every birth in every family for the past six years was registered. The state health department helped to check the reports. Not only have those ladies become interested in the birth registration, but they instructed the people as to future reports and getting in touch with the health department on other matters. In handling the food proposition, Dr. Schenck said, they organized the housewives. These ladies appointed a committee in every district in the city; visited the stores, and reported everything they saw that did not suit them. To control tuberculosis, an antituberculosis league was organized. A clinic was opened at which a small entrance fee is charged. The league has about 3,000 members. Two nurses and one doctor do this work.

Dr. I. D. Rawlings, Chicago, said that hospitals are essential to the control of communicable diseases. Hospitals also make for much less hardship in the home. The quarantine restrictions in Chicago are very drastic in many respects. No worker can live at home unless absolutely shut off from all communication with his family when a major disease is under quarantine, hence, it is a kindness to that family to place the patient in a hospital where the care is far superior and the death rate smaller. Chicago is not doing much on prenatal work because of lack of funds. The requirements of the state department of health in the various states should be reasonable but effective, and then the communities in that state should be required to live up to these requirements. Scarcely a day passes that the Chicago Health Department does not ask cooperation of the police department in enforcing these requirements. About 180 cases of venereal disease are reported each week through the courts, and in many instances the judge paroles in the regular routine manner. These people are either paroled to a physician, who will assume responsibility for treatment of those patients, and also guarantee that these women will not infect others while under treatment. Some persons who cannot be paroled are placed under treatment in a hospital set aside for that purpose.

Dr. O. B. Nesbit, Gary, Ind., said that in Gary the "Children's Bureau" is making a survey of all children under 7 years of age. They are notified to come to school and a study is made of these children in the kindergarten and first grade. The parents are asked to be present at the examination. He believes that this work is more promising than the work of the visiting nurse. The parent should be encouraged to talk to the doctor. The people want to see and know what the doctor says about things; it is a point in school work that has been neglected.

Dr. Hasbrouck De Lamater, St. Joseph, Mo., said that in his city the salary of the full-time health officer is paid, in part, by the board of education and in part by the board of health, and also by means of donations from public spirited citizens. The duty of the health officer or director of hygiene is a preventive and educational one. Sickness comes under the Board of Public Welfare. They appoint their staff physicians, and all medical, surgical, obstetric cases are taken to the hospital or cared for in their homes by what they term the family physician. He is convinced that volunteer work in school inspection is worthless. The average practitioner will take care of his own patients first before he takes care of the school work. An ordinance in St. Joseph gives the director of hygiene power to go into the home and take out any infectious case, no matter what, even venereal disease, and hospitalize the patient. The system to carry on the public health work of the smaller cities, Dr. De Lamater said, must be adapted to that place. Too many men have been theoretical rather than practical.

Dr. Peter Brice, Montreal, Canada, said that he had compared the deaths and hospital cases in the sanatorium at Ottawa with those of the city of Hamilton, Ontario, both cities having about the same population. In Ottawa the death rate from tuberculosis has been high. Hamilton has been going down in the number of tuberculosis deaths. For several years the two cities have had sanatoriums or hospitals for advanced cases. In every respect the two cities have been similar. Ottawa has a very good organization, but Hamilton has a better organization. In 1916 Ottawa had 211 cases in the sanatorium. Hamilton had 246 cases. Ottawa had fifty-one deaths in the sanatorium; Hamilton had twelve cases. Hamilton had eighty-eight persons under 15 years of age under treatment out of the 246 cases. Ottawa had eighteen. Hamilton had 142 days' treatment for each case, on an average; Ottawa had ninety-five days. If the disease is discovered in its initial stage, and the patient is kept under treatment until practically cured, these cases will not become old cases, going to hospitals and dying, because they go in too late for treatment. The hospital is as essential as the visiting nurse, and the visiting nurse is as essential as the hospital. In Hamilton 90 per cent. of the patients in the sanatorium come through the nurses of the public schools. In Ottawa the nurses are not under the board of health, and they are not finding the early cases in children. The parochial schools have no nurses at all. The class of population whose children attend these schools furnishes the larger number of tuberculosis cases. Toronto has ninety-three public health nurses doing the district work. Last year they had eighty-six deaths in July among children under 1 year of age. Montreal had sixty with a population five times as great.

Dr. C. J. O. Hastings, Toronto, Canada, said that the control of communicable disease which has been looked on as the "be all and end all" of public health administration, is only the fractional part of it, although it is essential. Health work must begin with the expectant mother. The conditions under which she is living and the revenue of the home, etc., must be such as to make it possible for her to bring into the world a fit offspring. Toronto has made provision for prenatal care, and the care of the child of preschool age, a period sadly neglected in public health work. Mothers have been supervised during the expectant period at "well baby clinics," of which Toronto has twenty-three. The children are brought there to be weighed, measured and examined by physicians. The follow-up work is done by the public health nurse. The children of preschool age that are left there while the mothers are working are examined. In that way many defective conditions of the child will be removed before it enters school. Dr. Hastings said that nine tenths of the efficient public health work is educational. In Toronto this work is done by the health authorities and not by the board of education. The importance of a complete physical examination of every child entering the school, having the parent present, cannot be overestimated. It is effective education. In nine cases out of ten, the parent witnesses the examination, and is delighted to know that they have a physical record of his or her child, or attention may have been drawn to some defective condition. Before the children leave school a complete physical examination ought to be made again, to determine the best vocation in life for that child.

Toronto has ninety-three public health nurses, taking up all activities in connection with the department. That includes the activities in connection with the school work. There are no school nurses or tuberculosis nurses or child welfare nurses. The public health nurse is doing the combined work. The school nurse, when her duties are done, so far as school is concerned, is visiting some of the homes in the district, ascertaining the conditions there. By specializing in the home rather than on the disease, the work is done much more economically and much more efficiently.

DR. DONALD B. ARMSTRONG, Framingham, Mass., emphasized the value of using women in canvassing and covering the different sections of a community for various purposes as was done in Norfolk. Framingham made use of neighborhood committees, and in one year increased the number of registered births by nearly 30 per cent. He suggested that very frequently that type of an organization can be made a permanent organization by selecting, on various streets, the leaders, those who have the most enthusiasm, and making them a permanent group for that particular neighborhood. When called on they will attend to the distribution of literature, canvassing for medical examination, reporting of sickness as well as births, and other things. Framingham has also organized the schoolchildren into "health crusaders." This has also been tried out in other communities, and is proving very profitable. About 80 or 90 per cent. of the children are health crusaders. They are members of clubs in their own schools, and are helping in various ways to do different things in the community, such as sanitary inspection. This educates the youngsters and furnishes useful information. Each child keeps his own score card of public health activities and various hygienic practices that he is supposed to observe, such as hand washing before meals, sleeping a certain number of hours, etc. All of this proves to be very useful, and has interested the children so that they are now "thinking health" primarily.

DR. J. M. FURSTMAN, La Crosse, Wis., speaking of tuberculosis said that a combination of both the institution and nursing service would be ideal. But with the smaller communities, with 200 and 250 cases of tuberculosis and an institution accommodating, say, only forty-four cases, not much would be accomplished by hospitalization. With the general practitioner, most of the cases reported are far advanced cases. There is not any question that other members of the family have already become infected. Contagious disease hospitals in the smaller communities, the speaker said, are an expensive proposition. If an arrangement could be made for some of the smaller hospitals to make an addition to the hospitals to take care of communicable diseases, the maintenance cost would be less, and more cases could be admitted. He is satisfied that we can get considerably better results for the small amount of money it is going to cost to take care of these cases in the hospitals. A hospital for communicable diseases with a bed capacity of forty would cost $50,000. A small isolation hospital in connection with one of the hospitals gave facilities in La Crosse for taking care of twelve or fourteen people comfortably. This hospital has been remodeled, and now has facilities for about thirty-five. All the expense the city has had to bear is the taking care of the patient in the hospital. There is no overhead expense; no maintenance whatever. If that system can be adopted in the smaller communities, more cases can be hospitalized.

Ascaris Escapes Through Ear.—The little girl of 4 was taken suddenly with intense earache, but there was no fever, and paracentesis brought no pus. By the third day the child had syncopes, violent nystagmus and general convulsions, and then something was seen in the ear which resembled the wormlike mass from a tube of tooth paste. It was seized with Kocher forceps and proved to be a male ascaris nearly 6 inches long.—*Revue de laryngologie*, 1918, **39**, 358.

THE ORGANIZATION OF HEALTH DEPARTMENTS

IN CITIES OF ONE HUNDRED THOUSAND TO FIVE HUNDRED THOUSAND POPULATION

J. H. LANDIS, M.D.
Health Officer
CINCINNATI

No hard and fast rule can be laid down for the organization of health departments for all cities of between 100,000 and 500,000 population.

Very few cities present exactly the same health problems. It follows, therefore, that while a general plan may be suggested, this plan must be flexible enough to meet varying needs due to purely local conditions.

At the present time, it would be difficult to find two cities with the same organization. Some are governed by an independent board; others are a division of some other department, such as the service or safety department; and still others are under a commissioner of health appointed by the mayor. Some have charge of hospitals, insane asylums, charitable and correctional institutions, plumbing and building inspection. In some cities, school medical inspection is a school board function, in others a health department function. Others include street cleaning and the disposal of ashes and garbage.

This lack of system leaves one practically helpless to make comparisons or to arrive at a definite conclusion as to the per capita expenditure of a given city for purely preventive medicine work.

The chaotic state in which we find the subject is probably due largely to differences in state laws and to the revolutionary political period through which American cities have been struggling. Geographic location is also of importance because of the special problems that may confront officials of coast cities or those located on or near international boundary lines. To the foregoing may be added the tremendous strides made in our knowledge of the subject of disease prevention during the past quarter of a century, and the slowness or rapidity with which this knowledge is applied.

In dealing with this subject, it is understood that nothing more than a skeleton form of organization can be outlined, and that the population to be served is to be taken into consideration in determining the number of employees working for the particular city under question.

Control by a board of experts has advantages that are hard to duplicate in any other method of organization. Among these may be mentioned a continuous policy, practically free from political interference due to changes in administration. Public health work is a highly specialized branch of medicine, requiring a vast amount of time to acquire the knowledge necessary to secure efficient results. Change in the executive officer and his force with each change in the general administration of a city results in disintegrating a trained force and substituting one inexperienced and necessarily inefficient. While incumbency is not synonymous with honesty and efficiency, the experience gained in eight years of public health work has given me a very high opinion of the honesty and efficiency of the average individual if freedom of action is assured him in the performance of his duties. Service under an independent board insures freedom of action to a greater degree than can be hoped for when appointment comes from some other source.

Boards of health have legislative powers and are independent of other branches of the city government in passing necessary regulations. The work of the board necessarily gives it information concerning sanitary needs and the proper method of meeting them that is impracticable for others to acquire whose time is taken up largely with other duties. In other words, it specializes in its work, knows just what it wants, and takes the most direct method in securing it.

In their recommendations for an ideal health department for Minneapolis, Biggs and Winslow say:

> The administration of health laws, as in the case of most other municipal activities, should be in the hands of either a single expert or a small body of experts, in order to obtain the best results. In most city departments the single commissioner is preferable to the board. In the case of the health department, however, the framing of ordinances requires the exercise of legislative powers which can not be entrusted to a single officer. If there is a single health commissioner with no board, the ordinance framing power must be left in the council. With the complexity and rapid progress of public health science on the one hand, and the pressure of private interests on the other, such a course is certain to be disastrous. It is for this reason that whatever may be the case in other departments of government, sanitary policies and legislation and administration can be most successfully developed and carried out by a board.

The work of a department of health includes a wide variety of functions, making it necessary to group those closely related into different divisions. These, in turn, may occupy ground that is common to two or more divisions, so that the best results can be obtained only by the fullest cooperation between the various divisions. The work of the divisions of medical inspection, food inspection and the laboratory in a milk-borne epidemic of diphtheria or typhoid fever may be cited as examples of instances in which three or more divisions might be actively engaged in solving one problem.

While very few health departments perform the same functions, most of them have divisions of general administration, medical inspection, food inspection, sanitary inspection, laboratory, and vital statistics, and I shall give these divisions consideration in developing the title of this paper.

GENERAL ADMINISTRATION

To general administration belong the executive officer, the clerk and stenographers. The successful executive officer must have something in addition to a knowledge of the game to insure success; he may have a very wide knowledge of his duties and yet be a failure as an executive. Brusqueness and incivility are no longer accepted by the public as infallible signs of genius, or excused on the ground of temperament or eccentricity. He must be able to secure results and do it without creating opposition. The ability to refuse unreasonable demands and send the applicant away feeling that he has been the recipient of unusual favors is one possessed by few men, but one that is very essential to success in public health work. He must be able to harmonize the little jealousies that do so much to disorganize a force and destroy its efficiency. In a word, he must be not only a master craftsman, but he must have the personality that counts for success in any walk in life. Similar personal qualities are essential for a successful clerk, for the reason that one weak link in the chain destroys the usefulness of the whole.

Publicity might well be placed in the division of general administration. The public knows what it sees, hears or reads. Where one gains knowledge by seeing or hearing, thousands learn by reading. For this reason, the activities of a department should be placed before the newspaper-reading public by some one individual in the department with special aptitude for that kind of work.

FOOD INSPECTION

The division of food inspection should employ experts only. Laymen cannot be expected to have the exact knowledge necessary for efficient work. Milk and dairy, and meat inspectors should be graduates in veterinary medicine. Since adopting this rule, Cincinnati's meat inspection service has been placed on a par with government meat inspection. The chief of the division must be familiar with all varieties of food and their multitudinous forms of adulteration. My ideal of a chief food inspector is one with this knowledge and the heart of a gladiator, for he needs that quality to place "the fear of God" in the hearts of that small minority whose rascally actions lower the tone of the entire food industry.

Food inspection should include surveillance over all foods, and the places and persons engaged in the industry, with authority to enforce regulations necessary to protect the general public from articles detrimental to health. Most forms of adulteration are commercial frauds, and their detection could very properly be assigned to some other department. It is the meat and milk supplies and other perishable foods that require constant watchfulness on the part of the food inspection division. Close cooperation with the division of infectious diseases is necessary in order that food-infected foci may be located and proper steps taken to limit the spread of infectious diseases. One or more central points for the pasteurization of milk, under supervision of the health department, would be the most important step that could be taken to minimize the spread of infection through this important article of food.

MEDICAL INSPECTION

The division of medical inspection should have as its chief an expert in the differential diagnosis of the acute infections. Medical inspection should include medical relief of the poor, surveillance over infectious diseases, the enforcement of quarantine, school medical inspection, open air schools, pure milk stations, dental inspection, epidemiologic study of the acute infections, the isolation of diseased prostitutes, prenatal and postnatal instructions, prevention of infant mortality, control of tuberculosis with special reference to the removal and detention of vicious consumptives, and control of midwives with particular attention to the prevention of blindness.

Management of hospitals, insane asylums, and correctional or charitable institutions has no place in public health work except to control the method of admitting and discharging cases of infectious disease and general sanitation of the institution.

School medical inspection should be under the control of health departments. If carried on by the board of education, twilight zones of authority are created that cripple efficiency and give rise to needless friction. In other words, a division of authority always paves the way for inefficiency or leads to a duplication of effort and expense.

Full-time work is an absolute essential for district physicians if the best results are to be obtained and friction between the family physician and district physician is to be reduced to a minimum. Since the adoption of this policy in the Cincinnati Health Department, the work of the district physicians shows an increased efficiency of about 40 per cent., and misunderstanding with the general profession has practically disappeared. As they have no private practice, there is no ground for the suspicion that their acts may be inspired by selfish motives.

An adequate force of nurses is necessary to follow up the cases. Their influence in the home has been of the greatest importance in securing compliance with the recommendations of the district physicians.

The epidemiologic study of tuberculosis has been neglected. It is reasonable to believe that much could be learned that is now unknown concerning the spread of this disease, and the application of this knowledge would result in decreasing the morbidity and mortality rates from this cause. Every city of the first class should have one or more experts giving all their time to the study of this disease. These experts would logically be a part of the force engaged in carrying on the subdivision of tuberculosis.

The results obtained in cities devoting special attention to prenatal and postnatal instruction, to the control of ophthalmia neonatorum, and to the prevention of infant mortality, more than justify the expenditure necessary to provide the nursing and medical service.

Cincinnati's Association for the Welfare of the Blind, for example, in two years treated fifty-nine cases of "sore eyes" in new-born infants without blindness occurring in any case. This was done at an annual cost of about $1,000 to the Association, and includes the salary and incidental expenses for a nurse. It is not to be assumed that all of these cases would have resulted in blindness had the patients received no treatment, but the chances are that many of them would have become life-long dependents from this cause. If only one was saved from this fate, the cost of prevention returns a dividend to the state for education alone of 450 per cent. Assuming that all were saved from blindness, the return on the investment amounts to 13,075 per cent., or $261,500. The foregoing figures are very conservative, for they take no account of the blind pension and other expenses borne by public and private charity or of the economic loss due to impaired productive units.

Other figures showing the enormous economic saving brought about directly through public health work could be brought forward that would stagger the imagination.

The prevention of infant mortality means coordinating the efforts of numerous functions. Improvement in milk and water supply, the establishment of pure milk stations, the education of parents through lectures delivered to mothers' clubs, and through visiting nurses, have resulted in a reduction since 1910 in deaths from diarrheal diseases in infants under 2 years in Cincinnati from 104 to 40 per hundred thousand of population. The economic saving in eight years, assuming the potential value of an infant to be $1,000, amounts to over a million dollars, which amount is hundreds of thousands of dollars in excess of what it cost to run the entire health department during that period. Intelligent expenditure of a small amount of money on prenatal and postnatal instruction would result in still further reducing infant deaths from preventable causes.

SANITARY INSPECTION

The division of sanitary inspection is confronted with problems of sufficient importance to require a chief who is a graduate in sanitary engineering.

As plumbing, heating, lighting and ventilating are all vital factors in determining the average state of health of a community, it seems rational to include plumbing, building, workshop, factory and tenement house inspection in this division. In Cincinnati, plumbing, building and tenement house inspection are in a subdivision of the department of public safety, while workshop and factory inspection is performed by the state. The arrangement is not a happy one for the reason that it is impossible to define accurately the line of authority separating the three departments. Work is duplicated, and not infrequently one may find three sets of orders on the same property, differing one from the other according to the personal views of the inspectors.

Close cooperation should exist between the division of sanitary inspection and accredited delegates from labor unions. In Cincinnati, the sanitarians of organized labor meet with the sanitary chief twice each month. Information concerning insanitary conditions in workshops and factories is solicited, special care being observed to suppress the source of the complaint. A vast amount of good has been accomplished, and the unions are enthusiastic in their support of the plan. The complaints are referred to the building inspector, the state inspector, or the sanitary division of the health department, according to the nature of the complaint, and the proper authority to conduct an investigation. While the work described is not ordinarily found in a health department organization, it has much to commend it to those desiring to develop latent activities in a municipality. It is a means of education among a class of people who are more vitally interested in securing improved sanitary conditions than any other class in the community.

In the matter of dealing with nuisances, American cities could adopt European methods with advantages in the way both of increased efficiency and economy. The regular police are charged with this duty abroad. The plan has the advantage of a large force of inspectors; regular police officers cover their beats every day, often several times each day. Orders received from a man in uniform carry more weight than those coming from the average inspection force of a sanitary division. The notion that it is beneath the dignity of a regular policeman to report conditions threatening the health of citizens is foolish and needs radical revision. He should be made responsible for sanitary conditions on his beat, as well as for the safety of life and property.

The work of the building department and that of the division of sanitation of the health department necessarily bring the two functions into close relationship. Questions concerning sanitation very naturally belong to that division; those dealing with structural defects which may have no bearing on sanitation belong to the building inspector. Lack of light and air, the presence of dampness, inadequate sewage disposal, etc., are conditions detrimental to public health and may be due to structural defects, thereby placing the solution of the problem in both divisions of the city government. This necessarily means a division of authority and responsibility, and calls for the closest cooperation between the two.

In Cincinnati, a vacation ordinance has done much to simplify the work of both divisions.

LABORATORY

The laboratory division calls for the full-time services of expert chemists and bacteriologists. Chemical and bacteriologic examinations of water, milk and other foods subject to infection or liable to adulterations that may directly endanger the public health are indispensable, as are facilities for the free diagnosis of specimens from cases of diphtheria, typhoid fever, tuberculosis, rabies, etc. The manufacturing of antitoxins and vaccines entails an expense that few cities are justified in assuming, and one that is better left in the control of commercial houses.

The detection of frauds practiced for purely commercial reasons and the assaying of materials used in filling public contracts, which have no bearing on public health, have no place in a department of health laboratory.

VITAL STATISTICS

The vital statistician has been called "humanity's bookkeeper." He needs considerable in the way of tact to meet and overcome the eccentricities with which a very small minority of the medical profession burden themselves. The work includes the securing of reports and classification of births and deaths.

The reporting and classification of communicable diseases is so intimately bound up with the work of the division of medical inspection that it is included in that division of the Cincinnati health department.

CONCLUSION

In closing, it seems desirable to state that a department may have an ideal organization on paper but a very mediocre one in securing results. While a good plan is desirable, good results may be obtained in spite of the fact that the paper plan is full of defects.

In the long run, results are brought about by men who are qualified to carry out policies by a close and harmonious cooperation between chiefs of divisions and other departments of the city government. Without the proper qualifications and close cooperation, any scheme of health administration degenerates into a ghastly joke and a gruesome tragedy.

Killing Head and Body Lice.—In an article on the louse problem in the United States Army, printed in the *Review of War Medicine and Surgery*, October, 1918, the following method of killing head lice is given: Clip the hair of the head with a hair clipper and wash with a mixture of equal parts of vinegar and kerosene. This should be followed in a few hours by a bath of soap and hot water. Following this treatment a search should be made for nits and lice and if found the treatment should be repeated. For crab lice the same mixture is used, after shaving the pubic region, axillae, chest and legs. As mercurial ointment, which is sometimes used, may cause a dermatitis, yellow oxid of mercury 10 parts, salicylic acid 1 part and petrolatum 20 parts may be substituted. For body or clothes lice, heat, either dry, or, better, in the form of steam, is best. Other things suggested are the English N. C. I. powder, consisting of naphthalene 96 per cent., creosote 2 per cent. and iodoform 2 per cent. The powder is dusted over the underclothing and on the inside of the outer clothing once a week. Also crude oil 9, soft soap 5 and water 1 part, or, soft soap 10 and crude naphthalene 90.

CEREBRAL SPASTIC PARALYSIS *

M. E. BLAHD, M.D.
Interim Director of Surgery, Mount Sinai Hospital
AND
WALTER C. STERN, M.D.
Orthopedic Surgeon, Mount Sinai Hospital
CLEVELAND

The syndrome known as Little's disease was first brought to the attention of the profession by Little of London, who, in 1843, in a lecture before the London Orthopedic Institute, reported several cases of the disease, which since has borne his name.[1] For a great number of years, this syndrome was erroneously classified as a medical entity, without any regard for the numerous causative factors. Since its etiology has been more completely recognized, it has been found that instead of its being a single medical entity, there are a great number of conditions with various etiologic factors, all producing the same end-results classified as Little's disease.

Cerebral spastic paralysis, or hemiplégie cérébrale infantile, seems a better term by which to express the manifestations of these various etiologic factors. The latter have been well classified by Grossman[2] into three groups: 1. intra-uterine, or prenatal; (2) natal, or intrapartum, and (3) extra-uterine, or postnatal.

The most important prenatal factors are malformation of the brain, porencephaly, microcephalus, atrophy of one hemisphere, congenital cysts and cerebral disease. In the intrapartum etiology, the chief factors are intermeningeal hemorrhage, intercerebral hemorrhage, cerebral palsy, and degenerations of the pyramidal tract after premature delivery. Injuries to the skull with subdural hemorrhage, circumscribed encephalitis, sinus thrombosis and embolism, and syphilis constitute the chief extra-uterine causes. In order to facilitate a clearer conception of the manner in which all these enumerated factors may produce the same end-results, the physiologic pathology on which spastic paralysis is based must be studied.

Whenever there is a break in the continuity of a motor corticospinal tract, of which the pyramidal tract is the most important, there results a characteristic motor paralysis. Irrespective of whether the lesion be situated in the brain or the cord, the resulting paralysis will be the same. This paralysis consists of a paralytic and a spastic component.

ETIOLOGY

Normally, impulses are propelled along the pyramidal tract to the various muscle groups, enabling these muscles to perform certain voluntary motions; but when there is a break in some part of this tract, these impulses no longer reach the affected muscle, and they are consequently unable to carry out certain of these voluntary motions or all of them. This is termed the paralytic component. On the other hand, an involuntary spasticity of the muscles takes place, which adds itself to the actual paralysis and intensifies it. If this spasticity is examined more closely, it becomes evident that the underlying cause of the condition is the increased reflex excitability of the peripheral muscles. Sensory impulses arising in the skin, ligaments, joints, and especially the muscles, are propelled along the sensory peripheral nerves and the posterior nerve roots, through the gray matter of the cord and the anterior motor cells, along the motor roots and motor peripheral nerves to the muscles, forming the spinal cord reflex arc. It is this reflex which maintains muscle tonus, and keeps the muscles in a certain degree of fixation. For convenience sake, it has been termed the fixation reflex. The pyramidal tract contains fibers which have an inhibitory action on this fixation reflex, keeping it at a point equivalent to the normal muscle tonus. But when the inhibitory action of the pyramidal tract is destroyed, allowing the fixation reflexes to exercise their full power on the muscles, without any restraint whatever, they cause spastic muscle contractures. This is the spastic component of the paralysis. Proof of this theory may readily be found in the living human pathology. One need only examine a tabetic patient, and observe the flaccid condition of the muscles to note the comparison. There is a complete absence of muscle tonus, due to a break in the continuity of the fixation reflex arc, resulting from the degeneration of the posterior tracts of the cord. But more convincing than this is the clinical picture of a patient suffering from a lesion of the pyramidal tract, with marked muscle contractures, who secondarily acquires a tabes. The muscle contractures relax, and instead of a spastic paralysis there results a flaccid paralysis.

---

* From the Surgical and Orthopedic Divisions of Mt. Sinai Hospital, Cleveland.

* Read before the Section on Orthopedic Surgery at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

* Because of lack of space, this article is abridged in THE JOURNAL by the omission of the footnotes. The complete article appears in the author's reprints, a copy of which will be sent by the author on receipt of a stamped, self-addressed envelop.

After careful perusal of these pathophysiologic facts, one may readily see that any one of the previously enumerated etiologic factors, acting on the pyramidal tract, either in the brain or cord, may be the causative factor in the production of spastic paralysis; and the degree of impairment is dependent entirely on the extent of the involvement of the pyramidal tract.

It does not lie in the scope of this paper to discuss in detail the anatomic pathology of the various etiologic conditions which may produce this syndrome, since the end-result will be the same, regardless of whether the causative lesion produces an injury to the pyramidal tract by means of pressure, inflammation, edema or hemorrhage.

SYMPTOMS

The cardinal symptom characterizing cerebral spastic paralysis is a spastic rigidity of the muscles, varying in location and intensity with the motor areas involved. Sharpe[3] very clearly defines where the lesions may be encountered in the various degrees of paralysis.

In a spastic paraplegia, which results from a lesion situated over the upper portion of both motor areas, both legs are affected. Very often it is overlooked for several months after birth, but eventually the mother notices a rigidity of the muscles. When the child begins to walk, the posture is characteristic. There is a talipes equinus which varies in degrees of intensity. The heels are everted and the knees approximated. However, if the lesion is over the upper two thirds of the motor tracts, the arms as well as the legs are involved. In this condition, the feet are crossed in the pes equinus or equinovarus position. The whole body may at times become rigid. The hands are used awkwardly and very often it is difficult to raise the arms or to abduct them. In rare cases of extreme spastic diplegia, in which practically the entire muscular system is involved, the complete motor area of both cortical hemispheres is affected. However, the condition one most frequently encounters is that in which the lesion involves one cortical hemisphere and produces either a monoplegia—the impairment of a leg or arm on the opposite side—or a hemiplegia characterized by spasticity of both the arm and the leg or the entire side of the body opposite the lesion. The elbow and wrist joints are flexed and the arm is held close to the body. There is a flexion at the knee and hip joints and plantar flexion at the ankle joint. A slight paralysis may be found in one facial nerve. Sensory disturbances are rare. The knee jerks and reflexes are accentuated. Unilateral squint is often present.

Flexion contractures of the muscles are the product of hypertonicity and are accompanied by a corresponding overextension of opposing muscle groups, the extensors. There are, however, milder forms of spastic paralysis in which merely an awkwardness in gait is manifested. Athetoid movements and convulsions may often be observed in these patients.

The majority of cases, to be more exact 60 per cent., are due primarily to intracranial hemorrhage.[3] It is interesting to note that in these cases the intracranial pressure is not as great as in those in which intracranial tumors exist. Occasionally, however, one can make out the beginning of papilledema and "choked disk," which are so characteristic of intracranial tumors. The optic disk margins are found blurred and edematous and the retinal veins are dilated.

It is not difficult to make the diagnosis of spastic paralysis, since it is based on the spastic condition of the muscles, the increased reflex excitability, and the lack of muscular coordination. Very often, however, there are no focal symptoms which are indicative of the origin.

If permanent degeneration of the pyramidal tract has occurred, it is almost fruitless to attempt alleviation, for it is needless to say that destroyed nerve elements possess very little, if any, regenerative powers. Unless the basic elements, such as hemorrhage, are relieved soon after their occurrence, it will be futile to attack the brain in the hope of relieving the spasticity of the muscles. The same principle applies to brain cysts and other destructive tumors. Consequently, it is obvious that the treament, for the most part, is of necessity symptomatic and entirely dependent on the degree of spasticity and the extent of muscular involvement.

In addition, the surgeon must take into consideration the mental state of the patient. The degree of mental impairment is often such that surgical procedure is contraindicated. To make the after-treatment effective, intelligent cooperation is essential. These unfortunate beings are very often forced into seclusion and are dependent on their limited resources for mental development. As a result, their intellectual growth is often retarded. As a matter of fact, in a number of cases in which we operated, following resection of the posterior roots, we noted a marked improvement in mentality, which we attribute partly to the more favorable surroundings during their stay in the hospital.

TREATMENT

The treatment of spastic paralysis must, therefore, consist in restoring to the higher centers the power of useful, coordinate movement in the limb or limbs afflicted; in restoring muscle balance; in overcoming the ataxia, and in training the muscles to respond quickly and accurately to the normal centripetal stimuli of physiologic activity.

In the mildest patients, possessing a high grade of intelligence, it is quite feasible to accomplish this by long continued developmental and educational exercises. A perfect cure is never to be anticipated with this or any other method of treatment, but useful function can frequently be attained. In very young children, the Montessori system of education will be found useful in exercising the upper extremities. Such educational training must be carried through many years, and various types of exercises, apparatus and useful, purposeful motions (as in the curative workshops of adults) may be improvised to meet the demands of the case.

When the spasm of the muscles is greater and contractures exist to a greater or less degree, mechanical intervention becomes necessary in order to equalize the lack of balance in the muscles at the afflicted joints, before the educational training may be successfully carried out.

OPERATIVE PROCEDURE

Such operative procedures are ordinarily employed to weaken the power of the stronger spastic groups, which are as a rule constant in all cases. The muscles usually afflicted are the flexors of the wrist and fingers, the pronators of the forearm, the flexors of the elbow, the abductors of the thigh, the extensors of the knee and the plantar flexors of the foot. The following outline gives in brief the courses of treatment open to the surgeon:

1. Muscle and Tendon Operations:
    - (*a*) Forcible redressment and overcorrection.
    - (*b*) Tenotomy.
        1. Subcutaneous.
        2. Open.
    - (*c*) Tendon lengthening.
        1. Subcutaneous.
        2. Open.
    - (*d*) Muscle resection.
    - (*e*) Tendon transplantation.
    - (*f*) Muscle implantation.
2. Brain Operations:
    - (*a*) Trephining and evacuation of blood clots.
    - (*b*) Decompression.
    - (*c*) Excision or evacuation of cysts or tumors.
3. Motor Nerve Operations:
    - (*a*) The causation of temporary paralysis by means of various injections (Allison's method).
    - (*b*) The partial resection of the motor nerves leading to the spastic muscles (Stoffel's operation).
4. Centripetal (Sensory) Nerve Operations:
    - (*a*) Resection of the posterior nerve roots (Foerster's operation).

The choice of operation depends on the etiologic factor and on the necessity of weakening the spasm of definite muscle groups, to a degree approaching normal muscle tonus. Almost all the operations enumerated allow of fairly exact dosage, which is usually determined by the amount of overcorrection used or the amount of nerve tissue resected.

The patient must possess at least such promise of sufficiently high intelligence as to warrant a hope for the success of the educational after-treatment. In many cases, the intelligent mind seems to be awakened by a successful nerve operation, such as the Foerster operation, but too much ought not to be anticipated from this source. There are many cases in which the spasm is so completely in control of all muscle function, that any hope of improvement that might have been entertained must be abandoned. This is true in cases in which the involvement of the upper extremities is so great that spasm from their use will of itself spread to the corrected lower extremities in such measure, as to preclude success. The severe ataxic, the epileptic, the choreal and the athetoid cases are confessedly hopeless, and the patients are not to be operated on, except possibly for a few tenotomies, etc., to permit the improvement of certain fixed attitudes.

Forcible redressment with overcorrection is seldom advisable. The tearing and rupturing of muscle fibers, tendons or ligaments leads to great pain, which of itself calls forth muscle spasm and defeats the very object to be accomplished. One indication for this procedure may be found in the severe cases of spastic pes valgus, which can often be markedly improved by forcible correction. The simple fixation of a joint or member in maximal overcorrection under anesthesia, without the use of any force whatever, will be found very useful in mild spasm of the shoulder or elbow joints.

Tenotomy may usually be accomplished subcutaneously. When important nerves or blood vessels in the neck might be endangered, it is better to resort to the open operation. Tenotomy does not admit of exact dosage, and when there is danger that the opposing muscles will assume the permanent balance of power and give rise to the opposite deformity (as in the foot), it should never be done. In the correction of the flexion contracture at the knee, one of the weaker hamstrings should always be left intact, lest the unopposed strength of the quadriceps result in a permanently extended knee and a stiff knee gait.

Subcutaneous tendon lengthening presents the same disadvantages as to dosage as does simple tenotomy, and is of little value. The open tendon, lengthening with only a small amount of overcorrection, should be the operation of choice for the Achilles tendon, as spastic calcaneous usually results from a too free lengthening of this tendon.

Tendon shortening is rarely found necessary.

When muscles have no tendons (pronator quadratus), or when the tendons are not accessible, muscle resection or the freeing of the muscle body from its periosteal origin (Soutter's operation) is indicated.

It will be seldom found necessary to transplant tendons, because of the usual good strength of the active opponents. It is quite possible that in excessive pronation of the forearm, the muscle and tendon operations advised by Tubby for the relief of this condition, due to other causes than Little's disease, might be found useful. We know of no case of Little's disease in which this has been tried, but there is no reason why it should not be successful in suitable cases. This operation consists of the transference of the tendon of the pronator radii teres into the ulna, the resection of the pronator quadratus, and the transference of the flexor carpi ulnaris around the wrist to the radial side of the back of the hand.

AFTER-TREATMENT

These operations are all to be followed by a period of fixation in plaster in an overcorrected position. Care must be taken that the amount of overcorrection is quite exact, lest a deformity in the opposite direction should result. The greatest care must be taken with the foot. On the other hand, the overcorrection of the spasm of the adductor muscles must be complete. After a few weeks, the plaster may be temporarily removed and passive motions begun.

Too long fixation is harmful. It renders the joints stiff and painful, and often exudates may be found in the joints, especially the knee joint, after three to four weeks of continuous fixation.

Passive motions produce pain, and often give rise to all sorts of nervous or even neurotic outbursts. We have in mind one case of most severe spastic contractures of the lower extremities, beautifully overcome by means of a Foerster operation, in which the permanent muscle shortening and resulting deformity had to be overcome by tenotomy and overcorrection. This patient complained of so much pain in various muscle groups, and became so neurotic and even hysterical at the periods of massage and muscle training that these had to be abandoned, and the success of the operation was jeopardized for a long time. The patient was finally taught to walk, only to have an attack of influenza six months later, followed by such intolerable pain in the left hip joint that she absolutely refused to get on her feet again.

Passive motions are first carried out in bed and consist of abduction, adduction and rotation of the hips, and flexion and extension of the knees and feet.

As soon as possible, the motions must be performed actively. Finally the children are to be supported in an upright position by means of braces, apparatus or hand rings and compelled to learn, first, to stand and then carry out exercises in a standing position, keeping the head upright and the body erect at the same time. Often they can stand erect by merely leaning against a wall.

Foerster has called attention to the importance of teaching the use of the hips, knees and feet in their physiologic sequence. He noted that the children readily learned to shuffle along with the hips, knees and feet held straight but stiff, and after they had once learned to walk in this fashion, they could not be taught or compelled to walk in the normal manner. He advises that the children be placed with their faces against the wall and compelled to learn to flex their knees and ankles in this position. After this, they are to be taught to walk in "goose step" fashion, supported by crutches, walking chairs, etc.

For all this, almost unbelievable patience is absolutely necessary. Often six to eight hours a day are consumed in carrying out these stepping exercises, together with the finer movements of rotation of the thighs, flexion and extension of the ankles and toes, pronation and supination of the feet, and so on. Foerster recommends the continuation of this educational regimen for several years.

It is just in this particular that we have all fallen down, especially in this country. Few clinics have enough teachers and gymnastic instructors so that such instruction may be carried out for more than a few hours a day, and that for a few months only. Each case needs a veritable Mrs. Macy.

The operations on the brain have been carried out for the purpose of relieving the cause of the spasm. It is obvious that these procedures are indicated only in cases in which the spasticity arises from easily accessible portions of the cerebral tract and is not caused by disease or degeneration of the spinal pyramidal tract. We know of no way of accurately differentiating these cases into their appropriate groups, except in cases of undoubted birth trauma, in which examination of the eyegrounds suggests an increase in the intracranial pressure.

If, immediately after a difficult labor, the symptoms of intracranial irritation or pressure are marked and hemorrhage or a brain cyst can positively be diagnosed, the immediate decompression and evacuation of the clot or cyst is the operation of choice.

Unilateral convulsions alone, even if severe, are no indication for this operation, except in the presence of asphyxia and cyanosis. Mild unilateral twitchings not amounting to actual convulsions, even combined with asphyxia and cyanosis, are to be left alone, as the children usually recover with perfect muscular control.

To be successful, decompression must be performed within the first week of life. It has never seemed to us that the late trephining, with or without the evacuation of any possible cysts, could be of much avail on account of marked destruction of brain tissue. The later experiences of Sharpe and Farrell confirm this.

The causation of temporary paralysis by the injections of various drugs into the nerve trunks (Allison's method) has not yielded permanent results. The muscles are at first completely paralyzed, then only partially so, but finally the complete restoration of the previous nerve function occurs and the case is necessarily in the same state of muscle imbalance as before.

The partial resection of the motor nerves supplying the definite groups of overspastic muscles (Stoffel's operation), is based on a correct appreciation of the mechanics involved, and if it can be successfully carried out in precisely the same manner as the originator of the operation recommends, it will fill a definite place in the treatment of this affliction. With it, exact dosage and diminution of harmful muscle contracture ought to be secured, regardless of the appalling number of individual nerves it will be necessary to resect, even in the milder cases. The possibility of accurately carrying out this procedure, which must, of course, always be anatomically exact, in the larger common nerve trunks, as the sciatic, median, etc., depends on absolute constancy of the nerve pattern, and we know of no proof that this exists except Stoffel's own claims.

The possibility of regeneration of the resected nerve fibers must not be lost sight of in this procedure or in the Foerster operation, and sufficient nerve must be resected to avoid this condition.

The resection of the posterior nerve roots of the spinal cord, like the resection of certain parts of the motor nerves, does not aspire to remove the pathologic cause of the spasticity. It simply reduces the number of motor impulses which reach certain muscles or muscle groups and in this way relieves the spasm and brings the muscles to a state of contraction closely resembling normal muscle tonus. The same thing may be accomplished by interruption of the fixation reflex arc in any part of its course, and as we have shown in a previous chapter of this paper, is admirably accomplished by nature, by causing a degeneration of the posterior tracts of the cord in tabetic patients. Foerster selected the posterior roots, since this is the only part of the sensory system accessible to the surgeon's knife. The dosage is naturally dependent on the amount of involvement of the various muscle groups. The various nerve segments that supply these spastic muscles may be readily ascertained from tables published in any standard neurology.

METHODS OF DISTINGUISHING SENSORY AND MOTOR ROOTS

Various methods have been devised for the purpose of distinguishing between the sensory and motor roots, all of which may be classified under the following headings: physiologic, morphologic and anatomic.

The physiologic methods are dependent on electrical stimulation of the nerve roots, and are, perhaps, the most accurate, if properly and successfully carried out. On account of the close proximity of the posterior and anterior roots in the cauda equina, it is often impossible to apply the electric current to one root without stimulating a nearby root. For example, an electric current may be passing through a sensory root, which in turn is transmitted to a neighboring motor root, causing a muscle contraction, leading one to believe that the stimulated root is a motor nerve, whereas in reality it is a sensory nerve.

The morphologic methods, as the name implies, depend on the morphology of the nerve roots for their distinguishing factors. These methods are absolutely unreliable and may be discarded without further discussion.

The method we have used is the anatomic, and depends on the ligamentum denticulatum for the recognition of the posterior roots. The ligamentum denticulatum is a transparent, film-like membrane attached to the posterior roots, and is absent from the anterior roots. It is easy to recognize, and is very constant. The use of this method is reliable, and has served admirably in our series of cases. The location of the nerve to be resected is determined by the spinous process, under which it takes exit. A guiding spinous process may be permanently located by biting off its tip with a Rongeur forceps at the beginning of the operation.

If the proper nerve roots are selected, the spastic component of the paralysis may always be relieved and this, after all, seems to be the pertinent factor on which is based these children's inability to walk. When Foerster first described his operation, a great number of surgeons enthusiastically resected the posterior roots and were highly gratified by the immediate relief of spasticity which was obtained. But, as is often the case, they soon forgot about these poor patients and left them to work out their own salvation, with only an indifferent educational after-treatment. These patients quickly resumed their former habits and after a short time the spastic condition again returned. In our opinion, it is the lack of after-treatment rather than the regeneration of the posterior nerve roots which has caused most of the failures in operations of this kind.

MORTALITY

A word in regard to the mortality in resections of the posterior roots may not be amiss. In a series of twenty-two cases, we have had two deaths, a mortality rate of 9 per cent. In the first case, death resulted from shock following chloroform anesthesia. In the second case, death was due to a purulent cerebrospinal meningitis. In all but our first case, we have been blocking off the higher centers of the cord and brain by means of injection of procain into the cord immediately above the seat of operation. This procedure is carried out for the prevention of shock and also for the purpose of using as little anesthetic as possible. After the bony structures have been removed it is usually possible to perform the remainder of the operation under the anesthesia produced by the procain injected into the cord. The use of this method permits a much freer handling of the cord, and, after all, this seems to be the most dangerous part of the operation. If all manipulations are gently and quickly carried out in combination with the injection of procain, the mortality rate of resection of the posterior roots should not be any higher than the average severe laparotomy. In any event, it should not exceed 5 per cent.

After these operations on the nerves, it will often be found necessary to overcome the permanent contractures and shortening of the muscles by means of the tendon and muscle operations previously described. These operations will differ in no way from those done primarily for the relief of the spasm except that overcorrection and fixation need not be so long.

The gymnastic and other educational exercises must be painstakingly carried out, as has already been mentioned.

CONCLUSIONS

We should like to point out several salient features in the study of cerebral spastic paralysis:

1. Little's disease is not a medical entity, but rather a syndrome resulting from various etiologic factors.
2. No stereotyped procedure can be used in the treatment of these cases, and the treatment is dependent on the etiologic factors, the condition of the muscles themselves, and the intelligence of the patient.
3. All forms of treatment will fail unless the educational after-treatment is conscientiously and painstakingly carried out.

ABSTRACT OF DISCUSSION

Dr. George B. Packard, Denver: We are apt to forget that all muscles are spastic in these cases. If one has, for instance, had a calcaneus deformity follow a tenotomy for equinus, he will never forget that all the muscles are spastic. The final outcome is largely a question of balance. If that is true, I often wonder whether we are not overlooking the value of tenotomy. In doing tenotomies, if you get just the right length of tendon, the results are excellent. In order to prevent the recurrence of the trouble, one must follow up the after treatment—that is, mechanical treatment—particularly at night. My method is not to have the patient wear a brace in the day time for more than a few weeks, but at night, when he is inclined to curl up the leg or foot it should be worn for several months; and in that way, I prevent the recurrence of the trouble. Of course, if we do not get just the right length of tendon, we can operate later to lengthen it still more; but the point is to get just the right length, in order to maintain the balance of the muscles.

Dr. Ethan H. Smith, San Francisco: One of the most important features in these cases is the anesthetic. I have found that patients suffering from this disease bear general anesthesia less well than almost any other surgical cases. I am glad that the point was made of holding the parts in correction during sleep. That is important not only in this, but in all other conditions involving the lower extremities. The weight of the bed covers at night has a tendency to cause relapse of the deformity after correction in nearly all deformities of the lower extremity, and a carefully made night shoe or night apparatus is necessary in all cases.

Dr. Walter G. Stern, Cleveland: I agree with Dr. Packard that we must be careful not to overdo the correction. That is why I said that in lengthening the Achilles tendon, it is preferable to do an open tendon lengthening, in which we can accurately measure the amount of lengthening that we wish to make. The question of night bracing has puzzled me. Most children with this disease are not of high intelligence, and they do not bear well the application of rigid braces at night time. We must either fight with all the people around the hospital or lessen the bracing at night.

Of late years, we have been giving gas anesthesia and blocking the cord after we get to the dura by putting in procain. Most spastic cases will show tremor, etc., when first going under the anesthetic; but if the anesthetic is given by an expert anesthetist, these children take anesthesia as well as any one. In Ohio, we have not had very serious epidemics of infantile paralysis. It is my experience that, in comparison with this disease, I see a relatively high proportion of spastic cases. There is hardly a day passes that I do not see a new case of spastic paralysis. The condition is more frequent than is usually believed, because the general practitioner does not recognize it.

Dr. John Ridlon, Chicago: What is your guide to the operation on the Achilles tendon?

Dr. Stern: My guide is the desired position of the foot. Of course, you can get the same result by doing a subcutaneous tenotomy and putting the foot up in plaster in a right angle positon. But we have the fixation reflex there, by which the muscle is made to contract; and in doing a subcutaneous tenotomy alone, the contraction will pull up the severed end of the tendon too far. In the Achilles tendon, one can do an open tendon lengthening and suture the tendon at just the amount of connection one wishes to get.

Dr. Ridlon: I do not know just how much you get.

Dr. Stern: That depends on your judgment. I do not correct much beyond a right angle. I had some sad experiences, and found, as Dr. Packard did, a paralytic calcanous resulting. I thought that the method was not so much in fault as my own judgment, therefore I put the foot up in a lesser angle. On visiting the clinics of Chicago, I found that many men there use the open operation; and in trying that, I found that it was much more accurate as to the amount of lengthening, and I have had no bad results since.

STREPTOCOCCUS PNEUMONIA AND EMPYEMA

AN INFECTION AFFECTING EIGHT MEMBERS OF ONE FAMILY WITH SEVEN DEATHS

WALTER L. BIERRING, M.D.
C. B. LUGINBUHL, M.D.
DES MOINES, IOWA
AND
C. W. BURT, M.D.
VALLEY JUNCTION, IOWA

In connection with the report of Miller and Lusk,[1] based on an epidemic of streptococcus pneumonia and empyema at Camp Dodge from March to May, 1918, we wish to report a similar infection affecting eight members of one family with seven deaths, occurring in the city of Valley Junction, which adjoins Des Moines, and is about 17 miles south from Camp Dodge.

These cases developed at the same time as the outbreak of the disease at Camp Dodge. The family consisted of the father, the mother and seven children ranging in ages from 4 to 24 years. The first member of the family to be taken ill was a son, aged 18 years, who manifested the first symptoms, March 26, 1918, and died three days later; the father, aged 46, and three children, aged 4, 15 and 21 years, respectively, became ill, March 29, 1918, one dying, April 1, two, April 3, and one, April 4. The clinical diagnosis of the first five cases was acute pneumonia. Two sons, aged 8 and 24 years, were taken sick, March 30, the first dying, April 7, and the second, April 15.

In each of the last two cases a left empyema developed, and aspiration on the exudate formed a part of the treatment.

April 2, a daughter, aged 12 years, was the eighth member of the family to become ill, and the only one to survive.

The acute pneumonia terminated in a left empyema, the exudate being removed by aspiration at first and later by rib resection and drainage, the discharge persisting for three months. The corresponding lung contracted and obliterated to a large extent.

The mother was apparently not ill at any time.

A postmortem examination was permitted in only two of the cases, being made by one of us (Dr. Luginbuhl) April 3, 1918, on the father and the 4-year-old daughter. The anatomic changes were identical in the two instances: a bronchopneumonia more than a lobar type, with a seropurulent exudate in the left pleura, and a fibrinopurulent pericarditis. These changes correspond to those described by MacCallum[2] in the Camp Dodge epidemic.

While the bacteriologic examinations were very incomplete, the etiology was evidently identical in the eight cases.

Cultures obtained from the exudate in the two necropsies produced a growth of the *Streptococcus hemolyticus*, and a similar micro-organism was isolated from the pus obtained by drainage in the last case of the series.

There were no definite predisposing conditions to be determined in these cases, except the insanitary surroundings in which the family lived. A preceding infection, such as a measles or tonsillitis, was not present. Each case was characterized by a sudden onset.

It will be noted that the virulence of the infection was more marked in the first five cases, there being a longer period of illness in the next two fatal cases, while the last patient of the series recovered.

The similarity between the cases reported herewith and those of the Camp Dodge epidemic suggests a common infective agent with variable degrees of virulence.

Legislation for Physical Training.—In an article on "State Legislation for Physical Training," Dr. Thomas A. Storey, inspector of physical training for the state of New York, shows that since May 15, 1916, seven states have enacted school physical training laws. These states and the dates of the legislation are as follows: New York, May 15, 1916; New Jersey, Feb. 13, 1917; Nevada, March 21, 1917; Rhode Island, April 19, 1917; California, May 26, 1917; Maryland, March, 1918; Delaware, April 10, 1918. Illinois passed a law, June 26, 1915, but no financial provision was ever made for carrying it out. The program in New York requires six hours a week of physical training for every pupil above the age of 8 years in all elementary and secondary schools. In New Jersey the required training time is at least two and one half hours in each school week. In Nevada the carrying out of the law is assured by a tax of 5 mills on $100 of assessed valuation of all the taxable property of the state. In the other states appropriation of certain sums is made by the legislature. In California the time requirement in the elementary schools is twenty minutes each school day, and in the secondary schools at least two hours a week. Similar legislation has been proposed and considered in other states.

Military Medicine and Surgery

CERTAIN RESIDUALS OF EPIDEMIC CEREBROSPINAL MENINGITIS OBSERVED IN THE ARMY

AARON J. ROSANOFF, M.D. (Kings Park, N. Y.)
Major, M. C., U. S. Army,
PLATTSBURG BARRACKS, N. Y.

In the period from December, 1917, to February, 1918, a number of cases of epidemic cerebrospinal meningitis developed at Camp Beauregard, La. The patients were treated with specific serum administered both intravenously and intraspinally, and a number of them made uneventful recoveries from the infection. After a four or five weeks' period of convalescence in the base hospital at the camp they were as a rule granted a sixty days' furlough at home. On return from their furlough some of the men were found still to have certain residuals owing to which they were unable to go back to duty. Others did go back to duty but were found within a few days to be unable to perform it. All such patients were therefore readmitted to the base hospital. After a further period of from five to eight weeks' treatment and rest in the hospital they were still not in condition to go back to duty, and eighteen of them were on July 29 transferred to U. S. Army General Hospital No. 30, Plattsburg Barracks, N. Y.

At various other times and from other camps eight other postmeningitic patients were received at this hospital, and thus a rather unusual opportunity presented itself of studying the residuals of epidemic cerebrospinal meningitis.

In the past ten or twelve years a great deal has been published on the subject of epidemic cerebrospinal meningitis; but these publications have dealt almost exclusively with the acute phases of the disease, its bacteriology, modes of transmission, prophylaxis and specific therapy, and not with the residuals.

The cases that have thus come to our attention present a striking and fairly uniform syndrome made up of the following elements, given here in the order of their frequency:

1. Limitation of flexion of the spinal column.
2. Undue fatigability.
3. Pains in back, legs and head.
4. Tendency toward dizziness and faintness.
5. Muscular weakness.
6. Tendency toward blurring of vision associated with photophobia.
7. Impairment of appetite and sleep associated with a state of undernutrition.

The limitation of flexion of the spinal column is shown in all cases by inability to stoop over far enough to touch the toes with the tips of the fingers without bending the legs at the knees. One or two of our patients, on arriving at the hospital, were able by special effort to come within 6 inches, but most of them could not come within a foot, and one could stoop but very slightly. All have told us that prior to their attack of meningitis they had been able to do this, and some had been able to stoop far enough to place the palms of the hands on the ground.

The limitation of flexion is further shown in the cervical region by the patients, in the majority of cases, being unable to flex the head on the trunk so as to touch the sternum with the point of the chin—which most people normally can do. Some patients cannot come within 2 inches of touching.

Undue and unwonted fatigability is present in all cases, although it varies a good deal in degree. In one case, going up a flight of stairs or a short distance up hill or a few blocks even on level ground results in getting out of breath, palpitation, weakness, trembling, aches in the back and legs, and a feeling of exhaustion. In another case, the fact of undue fatigability is to be noted only by comparison with former endurance or with the endurance of other men in the organization.

Pains in the back, legs or head are present in all cases. In some cases it is constant and so severe as to make it impossible to maintain with comfort any position for more than a few minutes. In other cases it is slight or only occasional, or develops only on stooping or exertion. The favorite locations are, in order of frequency, the small of the back, the back of the head and upper part of the neck, the legs behind the knees, and the back between the shoulder blades. In some cases there is tenderness to deep pressure, and in one case the head is so sensitive that laying the hand lightly on top of it causes an increase of pain. In two cases there is great soreness in the tip of the coccyx, the patients having to sit either on one buttock or the other.

A tendency toward dizziness and faintness is present in almost all our patients, but also varies in degree. In some cases any sudden movement starts things whirling or causes black spots to come before the eyes, while severe or prolonged exertion causes the patient to become faint, lose consciousness, and fall; at least one of our patients had come to us with a transfer card diagnosis of "epilepsy following meningitis." In the milder cases even severe exertion brings on only slight or momentary dizziness. Stooping more than other movements excites this symptom. Arising from bed in the morning often brings it on. It develops more readily in the unshaded sunlight, especially on a warm day.

In the headaches, dizziness, faintness and losses of consciousness, and in the fact of these symptoms being especially apt to be brought on by exertion, stooping, sudden movements, or exposure to the sun, the postmeningitic condition closely resembles the well known condition that persists for years following severe cranial traumatisms.

Muscular weakness, as existing independently of the fatigability and of the pains, is shown particularly by feeble hand grips in more than half of our cases. Usually both grips are weakened, but often in an unequal degree. One patient, in other respects having a rather mild case, formerly as "strong as a tiger," is hardly able to turn the faucets in the lavatory.

The tendency toward blurring of vision is very common but also variable in degree. It becomes manifest when patients attempt to read, especially if the print is fine. After a few minutes or half an hour the letters begin to "run together;" if the patient rests a while he can continue the reading, but unless he has rested an hour or more the blurring will come on again more quickly than the first time.

It would seem that this trouble is due to a weakness of the ocular muscles; in some cases close application brings on diplopia; the ocular movements, however, as ordinarily tested, are as a rule not impaired. In those cases in which the tendency to blurring of vision is most marked there is also a degree of photophobia; at least two of our patients have had to wear smoked or colored glasses. In these cases there is sluggishness and limited excursion in the pupillary reaction to light; moreover, on continued exposure to bright light, the initial contraction soon gives way to relaxation; and it may be that the photophobia is dependent at least in part on weakness and fatigability of the concentric muscle fibers of the irides with resulting lack of shielding of the retina.

The impairment of appetite and sleep, sometimes associated with a state of slight subnutrition, is perhaps a secondary phenomenon. Many of our patients were formerly leading active outdoor lives, but have since been forced by their illness to remain almost wholly without exercise for months. The loss of sleep is almost invariably associated with pain; in some cases the patients have difficulty in getting into a comfortable position for sleep and toss around for hours before finally falling asleep; others fall asleep quickly, but wake up in the night on account of pain developing from the strain of being in one position.

Our cases have shown very considerable variation in severity of the symptoms and degree of disablement, as compared with one another, but not in the syndrome considered qualitatively. The quantitative variations seem to depend in part on severity of the original infection, or possibly the patient's resistance to it, and in part on the length of convalescence. The usual course is characterized by a very pronounced degree of disablement at the beginning of convalescence, progressive improvement for about a month or six weeks under rest without special treatment, and from then on an almost stationary residual condition persisting apparently indefinitely—in our cases from three months to over a year thus far.

Shortly following the admission of these patients to this hospital they were divided into groups, according to the degree of disablement and were placed under a regimen of graded hikes and exercises, such as neck bending and body bending. This was followed by striking and rapid improvement in some cases and in distinct though slight improvement in almost all within a month. Several of the patients can now bend over and touch the toes with the tips of the fingers without strain or pain and without getting a headache or becoming dizzy; their endurance has increased; and one of them took part in a lively game of baseball lasting more than an hour, and then felt fit to play another one.

It is, of course, too early to tell whether or not these patients, or any of them, can be completely restored; but our experience has already shown that in practically all of them the condition, which remains stationary for months under mere rest, can be confidently expected to improve at least to a certain extent under graded hikes and exercises.

Some explanation is perhaps due for presenting our observation in so unfinished a form. Our justification lies in the urgency of the practical problems that are involved. Almost in every cantonment in the country cases of meningitis have occurred since the beginning of mobilization. The postmeningitic syndrome has apparently received very little recognition, and only the more severely disabled cases have forced themselves on the attention of medical officers who have disposed of them in one way or another as cases of hysteria, neurasthenia, "psychoneurosis following meningitis," "neurosis due to lumbar puncture," neuritis, etc.

It seems to us not unlikely that many patients that have been returned to duty and even sent overseas might, on examination by one familiar with this syndrome, be found to be really incompletely restored and hardly fit for duty. In such cases it would be obviously in the interest of both the patients and the government to institute the necessary treatment prior to returning the soldiers to duty.

Perhaps the simplest way of meeting the situation would be by ordering the transfer of all patients with epidemic cerebrospinal meningitis, on their recovery from the infection, to some one designated Army hospital for convalescence and such further observation and treatment as they may require.

THE MEDICAL ORGANIZATION OF THE ITALIAN ARMY

THE NEUROPSYCHIATRIC SERVICE

SANTE NACCARATI, M.D.
NEW YORK

Dr. Heiser,[1] last January, gave a thorough and valuable account of the military medical organization at the Italian front. Although the article had been written before the Italian retreat of October, 1917, during which much material was lost and three quarters of the medical units had to undergo considerable changes, yet the medical service at the front in its efficiency remains as Dr. Heiser described it. There are about 700,000 hospital beds within the zone of the armies, but their localization must not be revealed.

The medical service outside the zone of the armies is under the direction of the Director-General of the Army Medical Service, who is attached to the war office and whose position corresponds to that of Surgeon-General in the United States Army. He controls the so-called reserve hospitals, which are scattered all over the kingdom. Aside from these there are also other hospitals called territorial (about 160 in all, with a total of 30,000 beds), which are under the direction of the Italian Red Cross. There were in Italy, in the spring of 1918, 1,250 hospitals, including those of the Red Cross, with a capacity of 330,000 beds. These, added to the 700,000 beds existing within the zone of the armies, make the total military hospital capacity of Italy more than a million beds.

Considering that the area of Italy is 110,623 square miles, if we deduct the two provinces invaded lately and the others included in the zone of the armies (about 20,000 square miles), there are in Italy, aside from the 700,000 beds within the war zone 3⅔ beds per square mile.

Under the Director-General of the Army Medical Service are twelve colonels of the medical corps, each attached to an army corps and with jurisdiction over the hospitals within his army corps. Nominally there are twelve army corps, numbered from one to twelve, but practically there are eleven at present, as the fifth (Verona), being in the zone of the armies, is not controlled from the war office, but by the general staff.

The 1,250 hospitals have been distributed among the eleven army corps, according to the distance of the corps from the battle front, the building and transportation facilities and the climate. So in the district of the fourth army corps (Genoa) there are 241 hospitals (with twenty beds per square mile), because almost all the hotels of the Italian Riviera were taken over by the government and transformed into convalescence homes and hospitals, the climate of the Riviera being suitable for patients suffering from tuberculosis and other exhausting diseases. In the districts of the Second, Third and Sixth Army Corps (Alessandria, Milan and Bologna), which are located nearer to the battle front, there is an average of 7, 6½ and 5⅓ beds per square mile; while in the district of the Twelfth Army Corps (Sicily), which is far front the front, there is less than one bed per square mile. The effectiveness of Italian base hospitals has been greatly increased during the last few months. In the single district of Milan there are 53,000 beds, against 37,000 beds in November, 1917.

---

[1] Heiser, V. G.: Some of the Accomplishments of Italian Medical Men in the War, The Journal A. M. A., Jan. 5, 1918, p. 24.

In each army corps district there is a hospital called "principale," with which all the others are connected. A colonel or a lieutenant-colonel of the Medical Corps is at the head of the "principale," while the other hospitals are directed by a major or a captain, according to the number of patients. Most of the hospitals are for general patients, but many are reserved for certain classes of patients. In the matter of specialization, one is impressed with the number of categories and branches which have been installed and are successfully operated notwithstanding the difficulties and emergencies of the present time. The specialized hospitals include medical, surgical, ophthalmic, trachomatous with secretion, trachomatous without secretion, neurologic, orthopedic, infectious, contagious, psychiatric, stomatologic, venereal, dermatologic, otologic, isolation, malarial, tuberculous, crippled, climatic, convalescent, invalids', autolesionist,[2] diagnostic for tuberculosis and medicolegal, and there are schools of reeducation for the blind, agricultural schools for invalids, etc.

THE NEUROPSYCHIATRIC SERVICE

The Neuropsychiatric Service is one of the best services in the Italian army. Italy, having entered the world war nine months after the other allies, had time enough to study all the problems connected with the medical organization and was in a position to avail herself of the experiences of the other nations. While in France the Neuropsychiatric Service as a special unit was organized a long time after the war broke out, in Italy it started with the war. Moreover, Italy led the other nations in creating the so-called advanced neuropsychiatric sections, which are first line hospitals or sections of field hospitals, where the neuropsychiatric patients are first taken for diagnosis, distribution and eventual treatment. These advanced neuropsychiatric sections of the armies originated in Italy in September, 1915, three and one-half months after Italy declared war, after a short experimental period. In France, where the Neuropsychiatric Service has now reached perfection, it was not until April, 1916, that a committee composed of Drs. Chaslin, Colin and Truelle, chosen by the medicopsychologic society of Paris, proposed and obtained the creation of similar sanitary sections.

In order to give an idea of the whole Neuropsychiatric Service of the Italian army, distinction must be made between the neuropsychiatric service in the zones of the armies, and the psychiatric and neurologic services outside the war zone.

The entire Neuropsychiatric Service is under the supervision of Dr. Tamburini, professor of psychiatry at the University of Rome, who is the consulting psychiatrist general to the war office.

1. *The Neuropsychiatric Units in the Zones of the Armies.*—These are mixed formations composed of:

(*a*) Advanced Neuropsychiatric Sections: These, as stated, are located in the first lines, either as wards of field hospitals or as separate hospitals. They have a limited number of beds, ranging from ten to 150. The neuropsychiatric patients are sent there either directly from the firing lines or from other field hospitals. A first examination separates the mild cases from the serious ones. The former patients are kept there and treated for a short period of time, after which most of them recover and are sent back to their regiments, save a few who require further observation or treatment, and these are sent to the neuropsychiatric center of the respective army. The latter are sent directly to the nearer neuropsychiatric center, after all the important anamnestic data, the clinical history and a provisional diagnosis have been obtained.

(*b*) Neuropsychiatric Centers of the Armies: These are units, one for each army, located in the rear, usually in the same town where the director of the Army Medical Service of the army resides. They occupy large, modern hospitals fitted with apparatus for diagnosis and physical therapy, where patients sent from the advanced neuropsychiatric section are received and submitted to a more accurate and rigorous examination. Here those functional cases, emotive, confused, etc., which, if transferred directly to reserve hospitals outside the war zone, as it was customary at the beginning, would become chronic, are treated until the patients are fit for service again. Those suspected of malingering are kept under strict observation until they are exposed or found mentally affected, in which case they are either recommended to a board of survey for medicolegal decisions, or are sent with the other serious cases to the reserve psychopathic hospitals outside the war zone. This occurs only when all means of treatment have failed and when the diagnosis of psychoses or organic neurologic lesion requiring long treatment is made. Recently, after the creation of the distribution center of Reggio Emilia, it was decided that all such cases should be directed to this center, for whatever decision.

The whole neuropsychiatric service of the zones of the armies is under the direction of neurologists and psychiatrists (one for each army) of unquestionable merit, chosen from among the best in the service, who have been connected for many years with neuropsychiatric clinics of the universities. A staff of trained neurologists and psychiatrists is attached to each neuropsychiatric center.

2. *The Neuropsychiatric Service Outside the War Zone.*—While the neuropsychiatric units at the front are mixed formations, a condition dictated by emergency and practical reasons rather than by scientific ones, the units outside the war zone are either neurologic or psychiatric. These include reserve military hospitals, university clinics and asylums, and constitute (*a*) the psychiatric sections and (*b*) the neurologic centers.

(*a*) The Psychiatric Service: This deals with two kinds of patients: (1) Psychopaths requiring further clinical observation or treatment or medicolegal decision, and (2) psychopaths that have to be interned in asylums or state hospitals. For practical purposes it has been decided to send the psychopathic soldiers to the hospitals nearest their birth places. This disposition facilitates a great deal the task of the psychiatrists in collecting all the necessary anamnestic data directly from the families of the patients, and enables the patients to live in their own environment, climatic and social. Those under observation remain there for a period of time not less than three months before they are discharged from the army and sent to state hospitals, of which there is one in each of the sixty-nine provinces of Italy. The psychiatric service outside the war zone is done in part by medical officers and in part by civilian psychiatrists, the chiefs of university clinics and asylums, who on account of their old age cannot be in active service. Towns where psychiatric sections are located are: Padua, Verona, Turin, Genoa, Parma, Alessandria, Reggio Emilia, Bologna, Ancona, Imola, Florence, Arezzo, Lucca, Siena, Perugia, Rome, Aquila, Bari, Catanzaro, Naples and Catania.

---

[2] Autolesionist refers to those who practice malingering by self-mutilation.

A distribution center for all the psychopaths from the war zone has been recently located at Reggio Emilia. This center is composed of five sections having a total capacity of 1,600 beds, of which 150 are for officers. One section is for general cases requiring observation and medicolegal decision; another is for the observation and distribution of all cases of hysteria, neurasthenia and epilepsy; another is a convalescent home for neurotics who had preliminary treatment elsewhere within the war zone, insufficient, however, for the complete restoration of their mental and nervous functions. The American Red Cross contributed generously in supplying this recent formation with medical and surgical material. In a recent editorial of an Italian paper of Reggio Emilia, high praises are paid to the American Red Cross and its medical director, Dr. Joseph Collins of New York, who, being a neurologist himself, takes great interest in this matter.

A plan is under consideration to create special hospitals for the degenerates, perverted and amoral, whose number is increasing among soldiers, not as a product of the war, but because, in the rush for enlistment, the psychologic investigation of the recruits is usually neglected. These subjects are discovered later on and brought to the attention of the medical officers, who at present cannot dispose of them, although they know by experience how dangerous they are to the community.

(*b*) The Neurologic Centers: There were in Italy before the Austro-German drive of October, 1917, eight neurologic centers modeled on the French system. Since that time the center of Treviso has been suppressed, owing to its proximity to the Piave line, and three new centers were created on account of the increasing number of neurologic cases. Actually the neurologic centers are distributed as follows:

Milan, which is a distributing center for the organic cases coming from the battle front of the fifth and first armies. It is the largest one, composed of several hospitals for a total of more than 1,000 beds.

Pavia, 600 beds. This center is under the direction of the histologist Camillo Golgi, who went from the laboratory to give his valuable service for the solution of social problems arising from the war, and to devote himself to the present and future welfare of those wounded soldiers affected with organic neurologic lesions, who, without having lost limbs in the anatomic sense, have lost their function. These men, like the anatomically mutilated, have sacrificed their limbs. Physiologically they are crippled also, and deserve the same credit and help from their country as those who have had one or more of their limbs amputated; therefore, he called them the "functionally mutilated."

The other centers are: Genoa, 200 beds; Bologna, 300; Siena, 500; Ancona, 280; Rome, 310; Naples, 600; Bari, 150, and Catania, 250.

All these centers are equipped with modern apparatus for electromechanotherapy and diagnosis.

A notable innovation, which started in Milan and is proving most successful, is the institution of special occupational classes for the neurologic patients. These are by no means real schools for reeducation. Their scope is to furnish those patients who are able to do something during their period of treatment with a light occupation which, without tiring them, keeps them psychically active. For those patients who have either organic or functional disorders, the manual work, conveniently chosen and applied, is a wonderful therapeutic procedure, either from the point of view of the motor reeducation of the nervous and muscular system, or from the point of view of psychic reeducation of will. In many functional diseases of the nervous system, in which aboulia and psychic depression are prominent features, working is a splendid stimulus to rewaken and keep alive the individual energies and activities, which otherwise would be lost forever, and any later attempt for reeducation would prove either useless or a most difficult task.

WORK ACCOMPLISHED

It would be out of the field of this article to speak at length of the wonderful work done by the Italian psychiatrists and neurologists during this war; but I will give a few data.

There are about 20,000 patients, soldiers and officers, who are admitted in a year to the psychiatric and neurologic reserve hospitals. This number does not include those successfully treated in the neuropsychiatric sections and centers of the armies. The latter units have proved of great value in reducing the number of permanently unfit by preventing, with appropriate and timely treatment at the front, many of the sensorimotor psychoneurotics from becoming sensitive-motor neurotics, which would mean the definite loss of the patient to the army.

V. Bianchi, consulting neurologist and psychiatrist of the Second army, reports that of a hundred patients sent to his department, 50 per cent. were able to return to service after a short period of treatment or furlough. Of the remaining 50 per cent., one third had to be sent to psychopathic hospitals, but only one half of these were declared insane and ultimately sent to an asylum. The other two thirds were declared temporarily or permanently unfit for service, which means that they were either discharged from the army or sent to the centers outside the war zone for medicolegal decisions.

The problem of dealing with the neuropsychiatric invalids of war is one of capital importance. So far it has been given due attention in Italy. Aside from the help which the government has been given to this matter, a committee for war invalids has been organized in Rome with the purpose of assisting in every possible manner those soldiers who have cerebral, spinal and peripheral nerve lesions, and especially those who because of unusual and violent emotions reported in battle became functionally mutilated, namely, the invalids of the nerves, of the sight, of the hearing, of the speech and of the mind.

CHRONIC SKIN AFFECTIONS IN THE SOLDIER

C. J. HAILPERIN, M.D. (Newark, N. J.)
Captain, M. C., U. S. Army
CAMP LEE, PETERSBURG, VA.

My object in this paper is to point out the importance of looking for skin lesions, particularly those of a chronic nature, when examining men for the Army. From an examination of almost 8,000 men at the mustering office, and from a large experience in the dermatologic wards of the base hospital, I have been impressed by the potential and actual loss to the military service in accepting men who are suffering from chronic or recurrent dermatoses.

There are many types of skin affections which in ordinary civil life are of comparatively little significance. Many men go through life with these troubles without suffering any great inconvenience. When these men enter the Army, however, and are subjected to the physical and mental strain incident to Army life, they begin to have an aggravation of their trouble. They soon become incapacitated for work, and are sent to the infirmary or hospital for treatment. Many of these patients improve under rest and proper care, only to relapse soon after their return to duty. A sick or disabled man is a tax on the military organization. He cannot work; he requires medical attention; and to that extent he is a liability rather than an asset.

The accompanying table gives the various types of dermatoses as found among approximately 8,000 white men within a few days after their arrival at Camp Lee. Incidentally, this table also gives the number of men found with open syphilitic lesions, such as chancres, mucous patches and condylomas.

DERMATOSES AMONG EIGHT THOUSAND MEN

Acne keloid	1	Ichthyosis	8
Acne pustulosa	75	Lupus vulgaris	1
Acne rosacea	1	Parapsoriasis	1
Alopecia areata	8	Pediculosis corporis	1
Cysts, sebaceous (scalp)	3	Pediculosis pubis	3
Canities	2	Pityriasis versicolor	109
Dermatitis venenata	1	Psoriasis	40
Eczema, chronic	16	Purpura	2
Eczema, seborrheic	18	Scabies	20
Erythrasma	2	Syphilis (open lesions)	125
Folliculitis	11	Trichophytosis corporis	3
Erythema multiforme	4	Ulcer, varicose	2
Lipomas	4	Urticaria	5
Herpes zoster	2	Urticaria pigmentosa	1

Many of these diseases are of little significance from the standpoint of military service; but eczema gives considerable trouble, particularly if it affects the lower extremities. Among the men examined are many who give a history of chronic eczema, but who do not show any active manifestations. Active military life causes a return of their trouble, and they are then sent to the hospital for treatment.

REPORTS OF CASES

Case 1.—C., admitted to the hospital after being in service twenty-four days, gave a history of repeated attacks of papulovesicular eczema, which began six years before. On admission he presented an acute vesicular and weeping eczema of both feet, while on both hands there was a diffuse papulovesicular eruption. As the result of treatment, the inflammation gradually subsided after six weeks at the hospital. This man has now returned to duty, but will probably have a recurrence of his trouble.[1]

Case 2.—F. had had attacks of eczema for the past three years, particularly in the summer time. The present trouble began after being in service six months. A papular eruption appeared on the dorsum of both hands, and then spread to the arms and trunk. The patient was treated at the infirmary for two months, but the condition became worse. He was then admitted to the base hospital and discharged as improved after two weeks. Ten days later he was readmitted. On admission he presented a generalized erythematovesicular eczema that covered practically the entire body except the face and scalp. Some parts of the body, as the groins and axillary regions, showed considerable weeping. After more than two months of treatment there was only a moderate amelioration of the disease, and the patient had to be recommended for discharge from the service.

Case 3.—K., admitted to the base hospital after being in service about two months, gave a history of general pruritus and eczema of the right leg for the past ten years. The itching and inflammation would subside somewhat during the winter, but would become aggravated again with the approach of summer. The present attack began about three weeks previous to admission with a papular eruption on the hands and the body. On admission the patient presented a vesicular eczema of the face, neck and ears, while in the right popliteal space there was a thickened, red, scaly patch of chronic eczema. Both legs showed numerous excoriations as the result of scratching. The arms and trunk showed numerous erythematous and scaly patches. After prolonged treatment with very little benefit the patient was finally recommended for discharge from the Army.

Case 4.—Y., admitted to the hospital after two months' service, presented an interesting family history in that his mother, two brothers and one sister were suffering from a similar skin disease. The patient had had trouble with his hands and feet since he learned to walk. Large blebs would form on the palms and soles as the result of mechanical pressure. These lesions were present when the patient was mustered into service. After doing military duty for a few weeks, his condition became so painful that he was sent to the hospital for treatment. On admission the soles and palms showed a squamous condition as the result of the previous bleb formations. There was also a moderate hyperkeratosis of both plantar surfaces. While under observation at the hospital several new blebs have appeared on soles with very little inflammatory reaction. They heal without any atrophy or scar formations. The patient has now been in the hospital about six weeks without any marked benefit.

Case 5.—McD. had been in the service one month when admitted to the base hospital. Several members of the family had the same trouble. On admission he presented a marked hyperkeratosis of the soles of both feet and several deep fissures extending through the skin into the subcutaneous tissues. Walking was quite painful. Several weeks of treatment have thus far proved of little benefit. It is clearly evident that this man will never make a soldier, particularly as his condition has existed now for many years.

The histories of these and many other patients show that they are very difficult to cure permanently, and they will ultimately have to be sent home.

CONCLUSIONS

1. Chronic skin diseases, and particularly chronic eczema, are very resistant to treatment, and usually incapacitate men for military service.

---

[1] The patient returned to the hospital after being out six days. His condition is just as bad as it was at his first admittance, and he will have to be discharged for physical disability.

2. Examining boards should inquire into the past history, and be on the lookout for evidence of chronic eczema particularly.

3. Men with chronic dermatoses should be placed under observation before they are mustered in. Should they prove incurable, they can then be rejected. This, in my opinion, would be much simpler than discharging them after they have been inducted into the service.

AN INTERESTING REACTION TO LOUSE BITES*

WILLIAM MOORE, A.B.
St. Paul

Although the clothes louse is a known carrier of typhus and recurrent fevers and has recently been shown to be a carrier of trench fever, I am not aware of any published evidence that it may produce an illness due to a toxin or toxins introduced by its bite. Observations made while attempting to raise large numbers of lice for experimental purposes during the spring of 1918 appear to show that such an intoxication may result in persons bitten by large numbers of lice. The account given here is not presented as positive proof that such is the case, but rather to make available for other workers a record of our experiences.

Experiments were begun on the louse problem in the spring of 1917, with lice collected from the clothing of men in a municipal lodging house. They were kept in an electric incubator, heated to from 28 to 30 C. (82.4 to 86 F.). At first, attempts were made to feed them on rabbits, guinea-pigs, monkeys and pigs; but they refused to feed on either the rabbit or guinea-pig, and while they attempted to puncture the skin of a young pig, they were unsuccessful. The lice fed on the monkey but did not appear to thrive, which fact, together with the difficulty of so securing the monkey that it was unable to interfere with their feeding, caused a discontinuance of these methods. A laboratory assistant then undertook to feed them on his arm. Local irritation from the bites made it necessary to invite others to assist in feeding the lice. The work was continued in this manner until August, 1917, during which time no one person fed the lice more than two or three times a week, and at no time were there more than 400 lice. Miss Anna Wentz then took up the work as my assistant, and continued it until December. She cared for and fed all the lice, although they did not exceed several hundred at any one time. From April until December, when the work was temporarily discontinued, the lice received but one feeding a day, but when further experiments were started, March 12, it was determined to feed them twice a day, thus securing conditions more nearly normal.

During March, so many lice were destroyed in the experiments that there were at no time more than fifty lice to feed. By washing the arm with 95 per cent. alcohol immediately after the feeding and then treating it with a mixture of one-half glycerin and one-half ammonia, the local irritation was reduced to a minimum. During April, the number of lice on hand increased, and the first sign of an intoxication due to their bites was noted. Miss Wentz describes her condition as that of being generally tired and with a nearly continuous, dull, steady and at times, very severe headache at the base of the skull. Later chills and fever (the chill occurring before the fever) set in, with symptoms very similar to grip. The fever lasted for three days, being highest in the afternoon; but unfortunately no record of the temperature is available. At this time, a rash developed over the neck and shoulders, while a number of small blisters were noted on the arm, where the lice were fed. This illness occurred between April 15 and April 30, the exact date not being recorded, since at this time we had not associated the illness with the bites of the lice. About April 20, I took over the feeding of the lice with the result that Miss Wentz improved in health, until by May 6 all symptoms had disappeared.

Whereas Miss Wentz had started feeding with a small number of lice which gradually increased, I started feeding about 700 to 800 twice a day. Almost immediately a general tired feeling was noticed in the calf of the legs and along the shin bones, while on the soles of the feet and underneath the toes this tired feeling was so intense as often to prevent sleep until late in the night. An irritable and pessimistic state of mind developed. May 7, an illness resulted with symptoms very similar to grip, and a rash similar to German measles was present, particularly over the shoulders and abdomen. As German measles were prevalent in the community at that time, it was considered German measles; and after remaining in bed for several days, I returned to work and again took up the feeding of the lice. The general feeling, previously noted, was present with increasing intensity. By May 15, the number of lice in our reserve stock had increased to about 1,200, and, May 28, I was again forced to remain in bed. The family physician was called and diagnosed the case as possibly grip. The next day he was again called, since a distinct rash was present all over the body. The rash was considered quite typical of German measles, but other symptoms of measles were absent. The heart was normal, the pulse about 90, and the temperature varied from 100 to 102. A blood count revealed a normal number of leukocytes and red corpuscles. A severe headache was experienced, accompanied with pains in the legs, not only along the shins, but also in the calf of the leg and the soles of the feet, while intense pain was present in all the joints of the body. The appetite was lost for several days, and the tongue was heavily coated. Dr. A. D. Hirschfelder, who has been assisting on the louse problem, saw me at this time and considered that it was not German measles, nor was it grip, but might be trench fever. Glandular enlargement was absent and no enlargement of the spleen was noted. Recovery was complete except for a general weak condition by June 4.

I again took up the feeding of the lice, June 6, with the hope of producing the symptoms again and deciding if the illness was really caused by the lice and, if possible, whether it was trench fever. The lice numbered about 800 adults, which gradually died off while young lice hatched from the eggs, until by June 22 about 1,800 young lice were being fed. During the early period between June 6 and 15, no lassitude was noticed, but from about the 17th on, it gradually returned as the number of lice increased, until the 27th and 28th, when it was pronounced. On the 29th, I was feeling so miserable that it was a decided effort to get up in the morning and again feed the lice. The symptoms were the same as in the two previous illnesses. If the illness was due to the organism of trench fever, a day or two spent in the open with plenty of exercise would hardly prevent the attack, but if it was due to a toxin or toxins, it might be possible, by plenty of fresh air and exercise, to throw off the toxins and escape the attack; hence, the 29th and 30th were spent in the open, rowing and fishing. During the 29th, the symptoms were still quite pronounced, but gradually disappeared on the 30th, although a general tired feeling persisted for several days. Since that time, the lice have not been fed, and two weeks in July were spent on a vacation in the open. The result has been the total disappearance of the peculiar tired feeling in the legs and feet and a return to perfectly normal health.

---

* Published with the approval of the director as Paper 130 of the Journal Series of the Minnesota Agricultural Experiment Station.

CONCLUSION

The foregoing is suggestive that the clothes louse, if present in large numbers, may produce an illness, which appears to be an intoxication of the system with some toxin that they are capable of introducing at the time of feeding. It is also suggestive that some of the symptoms of trench fever encountered in certain cases may not be due to the organism of trench fever, but to certain toxins introduced by the lice.

AN APPARENTLY PRACTICAL METHOD FOR THE ISOLATION OF PFEIFFER'S BACILLUS FROM SPUTUM*

E. E. ECKER, Ph.D.
CLEVELAND

During preliminary investigations in the present epidemic, the isolation of *B. influenzae* from sputum was found to be a difficult task when the usual routine procedure of plating on human blood agar was followed. The difficulty in isolating by this method is due to the fact that other organisms, such as pneumococci, staphylococci and *Micrococcus catarrhalis*, tend to obscure the colonies of influenza bacilli and overgrow them. Therefore it can be readily seen that in most instances the element of chance in isolating the influenza bacillus by blood agar plates alone is great and the whole procedure uncertain.

In 1903, Cantani[1] reported the interesting observation that bile did not destroy the virulence of influenza bacilli. Cultures of these organisms and bile simultaneously introduced into the peritoneum of guinea-pigs invariably killed the animals. It occurred to me to use bile or bile salts because of the dissolving action of bile on pneumococci and its inhibitive effect on other accessory organisms. Sodium taurocholate was used in a strength of 0.5 per cent.

Bronchial secretions were mixed with the taurocholate solution, and the mixture was allowed to stand for at least twenty minutes and longer. After exposure, streaks were made on human blood agar plates. The method proved satisfactory, and after twenty hours' incubation at 37 C. (98.6 F.) minute, colorless, transparent droplet-like colonies were easily detected and differentiated.

The organisms stain nicely with aqueous fuchsin and measure about 0.5 or 0.6 micron by 0.2 or 0.3 micron. They are gram-negative and form irregular clusters with no definite arrangement. They often give the appearance of *B. coli.*

Subcutaneous injection of washings from slants into mice proved fatal to the animals within six or seven hours. The bacilli were readily obtained from the heart blood of the animals.

Materials for the work were kindly furnished us by Dr. J. S. S. Gardner of the U. S. Marine Hospital, Cleveland.

PATHOLOGIC SIMILARITY BETWEEN PNEUMONIA OF BUBONIC PLAGUE AND OF PANDEMIC INFLUENZA

DOUGLAS SYMMERS, M.D.
Professor of Pathology, University and Bellevue Hospital Medical College; Director of Laboratories, Bellevue and Allied Hospitals
NEW YORK

Since the commencement of the present epidemic of influenza in New York City I have had occasion to investigate by necropsy at the Willard Parker and Bellevue hospitals twenty cases of death from pneumonia occurring in the course of this remarkable infection. The changes in the lungs are those of a variety of confluent lobular exudative and hemorrhagic pneumonia in which the naked eye and microscopic features bear such a resemblance to the lesions in the pneumonic variety of bubonic plague as to provide an interesting study in similarities. There are, however, several features which serve as differential safeguards in separating the two diseases on anatomic grounds. If these should be eliminated or projected into the background—as not infrequently they are—then, indeed, the sum of the reactions of the pulmonary tissues to the prevailing infection is so nearly equivalent to that of pneumonic plague as described and depicted by investigators in the Far East that, were it not for the aid of modern bacteriologic methods, the pathologist of this climate might be tempted to the conclusion that the world is facing a pandemic of pneumonic plague in which, contrary to rule, the mortality is relatively low, rather than a pandemic of influenza with unusually frequent pneumonic complications and a far higher mortality than that exacted by any previous eruption of the same disease. The captious critic might object that an otherwise harmonious comparison is violated by the projection of superficial buboes into the picture of pneumonic plague and their absence from that of influenza, to which it may be replied that the pneumonic variety of plague is seldom accompanied by those bubonic manifestations from which the disease takes its name and with which, erroneously, all of its several anatomic forms seem to be associated in the minds of most physicians resident in this latitude. As far, however, as participation of the deeper nodes is concerned, the extent and distribution of thoracic and abdominal adenopathies in both diseases bear out the analogy. Moreover, the similarity of the two diseases is enforced by the clinical features, which are remarkably alike in many respects, and by the pathology of certain tissues other than the lungs. However impressive these observations may be, it is comforting to recall that the bacteriology of the prevailing pandemic is vouched for by a number of exceedingly able investigators, and that *Bacillus pestis* has found no place in their results.

---

[1] Cantani: Ztschr. f. Hyg. u. Infektionskr., 1903, **42**, 505.

In the greater number of all the cases of pneumonia associated with the prevailing epidemic, our experience at the Willard Parker and Bellevue hospitals is that the pleural cavities are free from excessive accumulation of fluid, only two exceptions having been found. In one of these the right pleural cavity was distended by cloudy, milklike fluid which had compressed the lung into an atelectatic mass scarcely larger than one's clenched fist, and the pleural was universally thickened. Obviously the empyema was one of long standing and had preceded the influenzal infection. In the second case, both pleural cavities were half filled with serofibrinous exudate, and the pleural membranes were extensively, although irregularly, obscured by collections of coarse, shaggy fibrin. In each of two other cases the pleura presented a localized, solitary patch of fibrinous exudate a few centimeters in diameter. In the remaining seventeen cases the pleurae were smooth, glistening and devoid of exudate. It is exceedingly important to note that, in this regard, the pathology of pneumonic plague is different from that of the existing pandemic influenza, Crowell, in twenty-five necropsies on subjects dead of plague in the Manchurian epidemic, having found extensive pleural exudates in every one.

The naked eye appearances of the lungs themselves, however, are highly suggestive, and, for descriptive purposes, may be thus grouped:

1. Cases with (*a*) extensive confluent lobular solidification of the lower lobes; (*b*) circumscribed or partially confluent consolidation of the lobules of the upper lobe, and (*c*) areas of acute vesicular emphysema. These cases without exception represented examples of rapidly fatal pneumonia.
2. More prolonged cases characterized by complete or almost complete consolidation of all or most of the lobes of both lungs, areas of acute vesicular emphysema occurring as an inconspicuous feature.
3. Those cases in which the pneumonic process is obviously subsiding.

THE ACUTE CASES

(*a*) The lower lobes of both lungs were always involved in company, never, in my experience, alone. The lower lobes were enlarged, heavy and extensively, often almost completely, consolidated. The involved areas presented a deep slate blue color mottled at intervals by slightly elevated pinkish or cream colored subpleural patches in which the inflammatory process had not progressed to its customary conclusion, or by areas of vesicular emphysema in which the dilated vesicles appeared as streaks or patches of minute, glistening, beadlike bodies. Petechial hemorrhages into the pleura or larger, splotchlike extravasations of blood were practically constant. As a rule, the extreme edges of the lung were spared by the solidifying process, the air vesicles undergoing, however, marked compensatory emphysematous changes. On section the substance of the lung cut readily. The cut surface presented a deep bluish or bluish black appearance, the substance was friable but less easily broken than that of the lung in croupous pneumonia, and the surface was of the smoothness of velvet, not a trace of fibrin being seen or felt. Scattered over the deep slate blue background were occasionally to be seen small, pinkish, granular-looking, firm patches in which, however, no suggestion of fibrinous granulations were apparent to the touch or microscopically. Pressure on the consolidated lobe released huge quantities of deeply blood stained serum in which there was a distinct milky tint due to the escape of leukocytic exudate from the vesicles. The cut ends of the smaller bronchi were sometimes to be distinguished by the escape of droplets of pus, oftener by frothy serum. The mucosa of the trachea and larger bronchi was greatly swollen, deep bluish red, and velvety, with an occasional grayish fleck of pseudomembrane lying on the surface. The peribronchial lymph nodes were markedly edematous and hyperemic, forming a mass around the root of the lung that sometimes attained remarkable proportions.

Microscopic examination of the deep bluish, firmly solidified portions of the lower lobe revealed the presence in the alveoli of huge numbers of red cells and polymorphonuclear leukocytes, either alone or in combination, and coagulated serum. Fibrin was absent. In many alveoli were quantities of large, rounded cells corresponding to desquamated vesicular epithelium. The interalveolar capillaries were intensely injected, as were those of the walls of the bronchi and bronchioles. The bronchioles were, for the greater part, filled by polymorphonuclear leukocytes, among which were clumps of desquamated epithelium.

(*b*) The upper lobes presented a somewhat different picture. The lowermost portions were divided into lobules of different sizes, some of them bluish and firm, others pinkish or reddish and less firm in consistency, while the uppermost parts and the extreme edges were markedly emphysematous and feathery. The microscopic changes in the solidified lobules varied, according to the degree of consolidation, from simple exudation of serum to distention of the vesicles by red cells or leukocytes or both. In other words, the pneumonic process in the upper lobes may be found in all stages of advancement, but the richly injected interalveolar capillaries and the frequent and abundant escape of red cells into the vesicles are apt to dominate the picture as a whole.

I shall not risk repetition in order to afford verification from an independent source of the similarity between the pulmonary changes in pneumonic plague and those of the prevailing pandemic of influenza as we have observed them at Bellevue Hospital. Suffice it to say that one has only to consult the admirable description of the lungs contained in Crowell's monograph[1] on plague, as he saw it in the Manchurian epidemic, to confirm the impression that the pulmonary changes in pandemic influenza are of the same essential variety, the constant pleural exudate in plague and the almost constant acute vesicular emphysema in influenza serving as the main points in the anatomic differentiation. Moreover, the colored illustrations that accompany Crowell's paper substantiate the resemblance to which I have ventured to call attention.

(*c*) The areas of acute vesicular emphysema so constantly to be found in association with the lobular pneumonia of pandemic influenza are of considerable clinical interest. For example, in two of our cases, rupture of distended air vesicles had taken place, probably near the apex of the lung, and the soft tissues in the supraclavicular spaces were crepitant with infiltrated air. In another case rupture had occurred, apparently in the vicinity of the root of the lung, since the soft tissues of the posterior aspect of the pericardium were permeated by myriads of emphysematous bullae varying in size from the head of a pin to that of a small marble. Gaseous particles extended thence into the soft tissues of the precordial area, downward toward the pericardial attachment to the central tendon of the diaphragm, forward into the retrosternal region, and thence through the upper aperture of the thorax into the neck and on to the lower portions of the face and downward into the subcutaneous tissues as far as the crest of the ilium on the left and the lower level of the costal slope on the right. In still another case, rupture had occurred directly into the left pleural cavity with the production of pneumothorax. In none of these cases was it possible for us to demonstrate at necropsy the actual point of rupture.

MORE PROLONGED CASES

In the Willard Parker and Bellevue Hospital necropsies we have several times observed almost complete consolidation of both lungs, particularly in individuals who had presented clinical indications of pneumonia for a relatively prolonged period. It was in two of these cases that the pleura presented localized patches of fibrinous exudate. In all of them the pulmonary substance was so extensively involved by the inflammatory process that the peripheral areas of vesicular emphysema were scarcely noticeable. In cases of this sort, also, the cut section of the lung sometimes showed pinhead sized or larger, rounded or irregularly outlined, grayish or cream colored bodies corresponding to confluent vesicular exudations of leukocytes, or there were areas in which, scattered over a considerable extent, the cut surface of the consolidated lung was marked by a network of grayish or grayish red lines surrounding deeply congested islands of consolidated tissue.

CASES IN WHICH PNEUMONIC PROCESS IS SUBSIDING

I have had an opportunity to study the lung in one case in which the pneumonic process was apparently subsiding. The patient was a man, about 30 years of age, who gave a history of having passed through a typical siege of influenzal pneumonia. He returned to work at an ill advised moment of convalescence and died suddenly. At necropsy the right side of the heart was greatly dilated and the muscle tissue was flabby. Both kidneys were large and congested, the tufts standing out as minute, reddish points. The spleen was enlarged and congested, weighing 275 gm. Both lungs were greatly increased in size. The upper lobes were emphysematous and feathery in consistency. The lower lobes were congested. In the lower lobe on the right side was a patch of consolidated tissue about the size of one's thumb, and similar but smaller areas were found to the extent of two or three lying in different parts of both lower lobes. These patches were deep bluish, firm, airless, and, on section, presented a perfectly smooth, velvety appearance, and quantities of semipurulent fluid could be squeezed from them. Scattered over the lower lobe, beneath the pleura, were several thumb-nail sized, pinkish patches, and it was observed that the pleura covering each of them was finely wrinkled. Evidently these patches represented areas in which the lung had undergone acute emphysematous alterations without complete loss of tone in the elastic fibrils, so that restitution was progressing. Microscopic examination of the solidified patches in the lungs revealed intense congestion of the interalveolar capillaries together with the presence in the air vesicles and smaller bronchi of dense collections of polymorphonuclear leukocytes. No red cells were apparent, and no fibrin.

Finally, I may be permitted to call attention to the occurrence of one instance in which the changes in the lungs of a soldier dead of influenza were identical with those originally described by Delafield as constituting an acute productive bronchopneumonia, and more recently studied by MacCallum[2] among the American troops in Texas. This variety of pneumonia is fairly common as a sequel of measles, and, according to MacCallum and Cole, is caused by a hemolytic streptococcus. It is marked by the presence in the lung of myriads of pin head sized, grayish white foci which are irregularly rounded or angulated and in the center of which a minute opening or depression may be discerned. In the case that I had an opportunity to study these spots were present literally in countless numbers scattered through both lungs, lying in a deep bluish red background and bearing a resemblance to miliary tubercles. On microscopic examination it was found that each whitish spot corresponded to a small bronchus whose lumen was partially or completely filled by polymorphonuclear leukocytes and clumps of desquamated epithelium. The connective tissue framework of the bronchus supported numbers of dilated and deeply injected capillary vessels between which were round cells. The alveoli in the vicinity or at a distance were filled either by polymorphonuclear leukocytes or by leukocytes and desquamated cells, some of the latter containing brownish yellow pigment granules. The interalveolar capillaries were universally injected. In short, the histologic changes were those of a very early stage of Delafield's, acute productive bronchopneumonia, the later stages of which, according to the original observations of the distinguished American pathologist,[3] are attended, among other things, by the growth of new connective tissue in the smaller and medium sized bronchi, in the interalveolar septums and thus by permanent changes of a productive nature.

THE CIRCULATORY SYSTEM

In the prevailing pandemic influenza, clinical indications of circulatory disturbances are numerous. For example, the nasopharynx is deeply congested, the skin is not uncommonly the seat of erythematous eruptions of various sorts, duskiness and cyanosis are common, the blood pressure is often alarmingly low, and the pulse is slow. At necropsy the signs of congestion are more intense and widespread than in any acute infective disease with which I am acquainted. The mucous membrane of the upper respiratory tract is swollen and deep red, the pulmonary capillaries, with scarcely a detectable exception, are crowded with red cells, and hemorrhages into the pleura and lung are common, the spleen is always deeply congested, the capillaries of the kidney from pelvis to capsule are filled to distention, the medulla of the suprarenals is frequently swollen and deep bluish red, the mucosa of the gastro-intestinal tract presents isolated or diffuse areas of injection, sometimes giving rise to hemorrhage by diapedesis, the lymph nodes are swollen and hyperemic to an unusual degree, the capillaries of the liver are injected to their fullest capacity, and the smaller vessels of the brain are likewise involved. In addition, the right side of the heart is dilated, especially the auricle, and the heart muscle is diffusely bluish and its capillaries are universally distended. Both the naked eye and microscopic appearances of the heart muscle fibers, however, are in the majority of cases indicative of a surprisingly excellent state of preservation. Cloudy swelling, in my experience, is exceptional.

[3] Delafield: Lectures on the *Practice* of Medicine, Part 2, p. 223.

The anatomic and histologic changes in the circulatory apparatus are of importance as indicating the necessity for stimulation from the instant that the diagnosis of influenza is made. Clinically, there are excellent reasons for believing that these changes are present from the earliest moments of infection. Moreover, from the opportunity that I have had to observe these cases at necropsy and in the living patient, it appears to me to be probable that the prevailing pandemic influenza is attended by pneumonic lesions from the beginning. Thus it has been shown that patients in whom it is impossible to detect signs of consolidation by ordinary methods of diagnosis, if subjected to roentgen-ray examination, reveal defects in the lower lobes that are to be interpreted only as areas of consolidation, subsequent developments confirming this view. Moreover, the distribution of the pathologic changes in the lungs is such as to suggest that the infection is introduced by way of the respiratory tract and that, in many cases, the initial lobular consolidations are situated deep in the substance of the lung, the process later developing in such fashion as to include the periphery. In those cases in which death has occurred twenty-four or thirty-six hours after the development of detectable pneumonic signs, it is scarcely conceivable that the massive solidification of the lungs found at necropsy could have taken place with corresponding rapidity. The suggestion naturally follows that, if one is to err at all let it be on the safe side, and that every case of pandemic influenza should be regarded from the outset as pneumonic, and so treated.

THE KIDNEYS

Microscopic examination of the kidneys reveals diffuse congestion of the capillary network throughout the entire organ, together with cloudy swelling of the tubular epithelium, most marked in the convoluted tubules and not infrequently well marked in the epithelium of Bowman's capsule. In this way the lumina of the tubules become partly occluded by granular débris, and similar material is to be found in the interval between capsule and tuft.

THE BRAIN

In those cases attended by delirium, the meninges of the brain are richly infiltrated by serous fluid and the capillaries are injected. Microscopic examination of the brain substance shows marked hyperemia. In one of our cases the convolutions of the brain were flattened and the brain tissues were noticeably dry. In another case purulent meningitis of pneumococcal origin was present.

JAUNDICE

In seven of the twenty cases investigated postmortem at Bellevue and Willard Parker hospitals, slight jaundice was present. Inquiry into this feature has shown that the mucous membrane of the duodenum is congested and swollen and that the exit of bile through the papilla of Vater is impeded to an extent sufficient, in part at least, to account for its retention in the bile capillaries and liver cells. Moreover, microscopic examination reveals the liver cells in such an advanced state of cloudy swelling that the bile capillaries are obstructed, the bile accumulating in the cells as minute greenish particles, finally being diverted, no doubt, into the circulation. In addition, the bile itself is extremely viscid, the contents of the gallbladder consisting of material of gelatinous consistence.

THE SPLEEN

In seven of the twenty cases of fatal influenza the spleen was normal in size, in nine it was slightly increased, and in the remaining four the organ was distinctly enlarged, three times to the extent of 300 gm. or over. The organ is deep blue; there is, in fact, a strong resemblance between the color of the spleen and that of the consolidated lower lobes of the lungs as seen through the pleura. On section the substance of the spleen is deep blue, friable rather than grumous—in which respect the consistence differs from the spleen of sepsis as commonly observed—and the follicles are unusually numerous.

ABORTION

The observation of Ball[4] that pregnant women are apt to abort as a result of influenzal infection is confirmed by our experience at Bellevue Hospital. The subject is now being investigated and will be made the object of a subsequent report.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

LUTEIN-H. W. & D.—The fully developed corpora lutea of the hog freed from foreign material, dried and powdered. One part lutein-H. W. & D. represents approximately four parts of the fresh substance (see N. N. R., 1918, p. 237).

The following dosage form has been accepted:

Lutein Tablets-H. W. & D., 2 Grains.—Each tablet contains lutein-H. W. & D., 2 grains.

France the Pioneer of Child Welfare Work.—Within the past few generations, we find that modern child welfare work, as we know it at the present time, has all started in Europe. France has had a declining birth rate for many years and to France we owe every child welfare movement we have, from its inception of school medical inspection in 1842 to the establishment of the first infant milk stations in 1890. All legislation for the protection and help of expectant mothers, including the feeding of children and of pregnant women, the day nursery, indeed, practically everything that we know of that is modern in child welfare work started in France, and not because of humanitarian impulses, but because it was absolutely necessary for France to keep alive and well every child born in that country.—Josephine Baker, M.D., *Health News*, New York.

WAR NEPHRITIS AND ALKALI THERAPY

Only those who cultivate an intelligent familiarity with the aims and methods of modern experimental medicine can appreciate to what degree it has become responsible not only for much needed improvements in the domain of diagnosis but also for changes in practical therapy. Illustrations abound on every side. A few years ago it was a conventional procedure to attempt to "flush out" the kidneys for all sorts of ills. Today it is fortunately realized by many clinicians—we wish that one could truthfully say by all—that in acute nephritis, for example, it is quite useless to give the patient large quantities of water to stimulate elimination, as this merely tends to irritate unnecessarily the kidneys, whose excreting powers are already crippled.

A further highly significant example of the wholesome outcome of research—animal experimentation, be it noted—may be cited in the work of MacNider[1] of the University of North Carolina on the renal functions. In the nephropathic condition induced by poisoning with uranium, he has shown not only that there is an association between the degree of kidney injury and the severity of the acid intoxication induced by this metal, but also that the intravenous use of an alkali in these animals will protect the kidney against the toxic effect of uranium and increase the efficiency of various diuretic substances. The stability of the acid-base equilibrium in any individual appears to be a factor of no small importance in relation to nephropathies. Earlier studies of MacNider[2] indicated that age may not be without significance in relation to the ease with which animals with kidney lesions develop acid intoxication. He has since demonstrated[1] that in contrast with normal subjects, naturally nephropathic animals have an unstable acid-base equilibrium. When the mechanism that controls this was subjected to the action of an agent, such as chloroform, which tends to induce an acid intoxication, the naturally nephropathic animals very rapidly developed such an intoxication, and became anuric. Normal animals, however, gave no evidence of acid intoxication, and in them the formation of urine was unaffected by the anesthetic. Furthermore, evidence has been presented to show that the naturally nephropathic animals, like those suffering from renal lesions experimentally induced, can be protected in varying degrees against toxic influences by the use of alkaline solutions. When failure to protect a damaged kidney occurs, it seems to be associated with rapid depletion of the alkali reserve of the blood and the development of acid intoxication. The degree of protection conferred by such alkalis as sodium carbonate is associated with the ability to maintain a normal acid-base equilibrium of the blood. Ordinary saline solutions have no such power.

MacNider's demonstrations have already caused alkali therapy to be given extensive trial in suitable human cases of war nephritis. By this is not meant an acute disease following a focus of infection, but rather that type of the renal disorder which shows an abrupt onset, with symptoms of dyspnea and edema. Unusual opportunity for such tests has been afforded among the troops in active service, where in contrast with the comparative rarity of acute nephritis in civil life large numbers of cases of this condition have been observed. Thus Keith and Thompson,[3] reporting from a base hospital in France to the British Medical Research Committee, assert that acidosis of moderate degree, measured by the alveolar carbon dioxid tension and the alkali reserve of the blood plasma, is generally present. One group of cases, designated as the resolving type, usually shows rapid improvement, disappearance of acidosis and reestablishment of good renal function through rest and simple dietotherapy. In the more severe nonresolving type of cases, however, alkali therapy seemed to be of distinct service in restoring both the normal acid-base relationship and improving the renal function.

Although acidosis was always accompanied by retention of substances normally excreted by the kidney, and spontaneous recovery from the acidosis followed the rapid elimination of these substances, the British investigators are of the opinion that the degree of acidosis encountered in war nephritis is secondary to impaired renal excretion. In this respect they agree with students of chronic nephropathics who have reached the conclusion that the acid intoxication developing in these conditions is a retention acidosis, and that the accumulation of nonvolatile acids is not responsible for the primary renal injury.[4] But when the acid substances accumulate, a further degeneration of epithelium may follow whereby the functional capacity of the kidney is arrested. It is this associated kidney injury which maintenance of acid-base equilibrium through administration of alkali seems to prevent.

DIET AND MILK SECRETION

Not long after the demonstration that beriberi is a disease attributable to a deficiency of the dietary came the announcement that the nursing infants of mothers who were suffering from the malady might also exhibit the symptoms. Judging from the ordinary chemical analyses there was no reason to assume that the milk furnished by the victims of beriberi was deficient or unusual in its content of the ordinary nutrients. Fats, proteins, carbohydrate and mineral salts seemed to be present in the usual proportions. Soon it began to appear that milk is the carrier of something more than these familiar ingredients. Milk contains vitamins of more than one type. Evidently these may fail to be transmitted to the secretion under certain conditions of malnutrition in the lactating mother. Thus we are brought face to face with the unanticipated possibility that a product, milk, highly prized as an almost ideal food, may be of excellent quality as judged by the traditional standards of purity and value, and yet may lack something quite as essential as the calory-yielding ingredients.

To what may the failure to produce perfect milk be charged? Does the synthetic capacity of the mammary gland fail in its duty, or is the production of nutritively imperfect milk associated with the diet of the lactating individual? The latter assumption seems somewhat unlikely in view of the now current doctrine that it is "breed" rather than "feed" which determines the character of the milk of any species. The mammary gland is not merely a filter which separates indiscriminately the varying pabulum brought to it by the blood stream. It seems to yield a product of almost invariable character despite profound alterations in the food intake of its bearer. This has been found to be true of cattle; and it was long ago reported that during the siege of Paris in 1870 young and vigorous women maintained and in some cases even induced gains in their suckling infants while these mothers themselves were actually or nearly starving.[5]

Nevertheless, the synthetic powers of the mammary gland have evident limitations. Underfeeding and faulty diets are not without effect on the milk secretion; but it has remained for the more recent methods of biologic analysis—as it has been termed in contrast with ordinary chemical examination—to reveal the more subtle deficiencies that are the expression of the relation between improper food supply and milk production. The substantiated facts in this connection have recently been summarized by McCollum and Simmonds[6] of the newly established School of Hygiene and Public Health at Johns Hopkins University, to whom are due fundamental researches in this field. The evidence, they state, seems conclusive that there is no special synthetic power of the mammary tissue by virtue of which amino-acids that are not found in the food can be formed. It is true that the milk contains proteins of uniquely good nutritive quality so that young animals may grow far better on a small concentration of these than on a much larger intake of plant proteins, for example. What happens, however, is this: The maternal organism selects certain of the amino-acids from the digestion products of the food and presents them in the milk incorporated in proteins in such proportions as make a very efficient transformation into the tissue proteins of the young. To quote McCollum and Simmonds, the mother "makes from her large intake of protein of rather poor quality a smaller output of protein of exceptional biologic value in the milk." This involves no synthesis of amino-acids de novo—only a selective absorption and reconstitution of the amino-acids which circulate in the blood, into complexes, the milk proteins, which in turn act as food that is very efficiently converted into body proteins for growth.

Similarly, according to McCollum, Simmonds and Pitz,[7] the mammary gland picks up from the blood the as yet chemically unidentified vitamins and passes them into the milk. They cannot be produced synthetically, for when they are absent from the mother's diet the vitamins are not found in the milk. The demonstration of the production of an otherwise normal milk poor or lacking in the fat-soluble or water-soluble vitamin or both, and therefore not capable of inducing growth, is an item of great moment for the science of nutrition. It deserves to be emphasized prominently that "milk production may take place under dietary conditions such that the product is deficient in certain complexes necessary for growth." And it is a seemingly logical inference from this that deficiencies in the supply of certain inorganic nutrients to the mother may lead to consequent imperfections in the milk she secretes. The quality of milk needs to be evaluated from new standpoints.

Today we know that many of the items in the food supply of the less well to do may be poor in vitamins. Breads and other products prepared from highly milled cereals, refined sugar, vegetable fats, butter substitutes and meats belong to the staples in the rations of these people. Perhaps, therefore, there is no undue exaggeration in this contention of the Johns Hopkins biochemists:

> There are tens of thousands of human mothers who are attempting to nurse infants on diets derived too largely from the seeds of plants and their milled products. Such diets produce inferior milks and may be the cause of grave disorders in the very young.

The remedy lies in the suitable extension of the dietary, in the use of green vegetables and fruits, and the inclusion of milk as far as economic conditions and financial resources allow.

INDICATIONS OF PHYSICAL OVEREXERTION

No one will dispute the general principle that exercise is essential to the well being of the human organism. Lack of use of a part or structure adapted to energetic functioning is likely to lead to poor nutrition and perhaps even to atrophy of the organ concerned. The phenomena of overexertion are not so generally recognized, although it would not be difficult for any physician to recall instances of damage thereby, particularly in relation to the circulatory apparatus. In other words, both overexertion and disuse of vital organs represent extremes of undesirable personal behavior. Perfect health demands a performance that shall steer a safe course between deficient exercise and undue effort.

The foregoing comments have an added import in connection with the problem of athletic sports. So long as these are in sole charge of untrained "trainers" there will be an element of danger in the win-at-all-costs attitude that is inculcated into the competitors in athletic games. In more recent years, protests against the possible sacrifice of health through undue exertion and break-neck strenuousness have begun to be heard. The "athletic heart" was the first symptom to awaken the exponents of unrestrained and indiscriminating effort in sports to the possibility of a real danger. Latterly the "athletic kidney" has commanded a little attention from the sober minded lovers of exercise in the form of sport; and it might not be amiss to assume the further possibility of a complex of disturbances involving the circulation as a whole and attributable to improper athletic effort. The kidney function has not as yet been taken into account as carefully as the heart activities, doubtless because it is somewhat less readily subjected to critical diagnostic analysis than are the cardiac performances.

The questions that perplex the student of the physiology of athletic exercise may for the most part be raised with equal propriety in connection with the work of the soldier. Military training has become a sort of nationalized athletic exercise in which the work to be done is not infrequently associated with tremendous exertion. Forced marches with heavy equipment, arduous toil at the guns on land and sea, and speeding-up moves at every turn of unexpected events in the uncertainties of war are experiences that mean a burden of physical effort to thousands of briefly trained young men. The problem of highest efficiency in war work as well as in peace play is bound up to some degree with the determination of the limit at which normal functioning ceases and the abnormal response manifests itself.

The military hygienist, therefore, not only is concerned with the conditions that determine the onset of fatigue, the enemy of all progress, but also asks how much the heart can endure and the kidneys tolerate without deterioration or impairment. There is, however, a category of persons who may well give him added concern. An army has its retinue of convalescents whose value for service depends on the ultimate degree of their recovery. A recent investigation by Feigl[1] at Hamburg shows that the usual clinical signs that the older methods of physical diagnosis depend on may not always be reliable indexes. He examined a considerable number of soldiers between the ages of 25 and 40 years who had regained a satisfactory state of nutrition and strength after prolonged stays in a military hospital. Most of them had experienced kidney disturbances as an involvement of the disease that invalided them, and had regained the status of being reported "practically well" when the tests were made. The task was a military march of 17 kilometers in three hours—not an unduly exacting trial for a soldier in good trim. The kidney functions were tested not only by an examination of the urine for protein and cellular structures but also by an analysis of the blood for evidences of retention of metabolites. The nonprotein nitrogen, urea, creatinin and uric acid were estimated. Incidentally it may be pointed out that the technic employed on these German soldiers was entirely that of made-in-America procedures. The results indicate that strenuous exercise which will not affect the functions of a well trained healthy person may nevertheless call forth evidences of imperfect restoration of capacity in apparently cured patients. Thus the newer and more subtle tests, such as the chemical micro-analysis of the blood affords, present information that warns—as The Journal has often warned before—of the danger of overstepping the physiologic limits of endurance in any physiologic activity.

Fly Prevention in the B. E. F.—Tangle-foot wire instead of paper is used to catch flies in hospitals, convalescent camps and like places. Pieces of hay-baling wire, 2 feet long, have a hook bent on one end and by dipping or with a brush are coated with a hot mixture of 4 pints of castor oil and 9½ pounds of crushed resin. The oil is heated and the resin gradually stirred in. When these wires are hung up, the flies alight on them and stick fast. When the wires become covered they are burned off and recoated for use again.

Current Comment

IT IS A WISE PHYSICIAN WHO KNOWS HIS OWN DANGER

Last week the deaths of 81 physicians were recorded in The Journal, occupying three pages. This week the deaths of 174 physicians are recorded, occupying five pages. The total number of deaths recorded in these two issues is 255, and of these 154 are definitely known to have been due to influenza or pneumonia; undoubtedly in the majority of instances in which the cause is not given, it was influenza. These obituaries are records of sacrifice to duty. A layman may, if he desires, keep from exposing himself to any infection; but the physician must go when called without thought of consequences to himself. However, as one considers the list one wonders whether or not some of these deaths might have been prevented by adopting some of the simple precautionary methods that have been suggested, such as the wearing of the face mask. This thought arose when we received a letter from a physician who, in sending in the names of two physicians who had died, said: "Dr. A. visited at the Great Lakes Naval Training Station an old patient who had influenza. Two days after his return home, Dr. A. came down with the disease. Dr. B. was called to see Dr. A. and examined his throat, Dr. A. coughing in his face. Two days later Dr. B. had the typical manifestations of the disease." It is proverbial that physicians, like preachers, give advice which they themselves do not consistently follow. It is a wise doctor who knows his own danger.

DIGESTIVE ABSURDITIES AGAIN

In the Correspondence department of this issue is a letter from a company whose "aromatic digestive tablets" had failed to measure up to the standard of strength declared on the label. In its defense, the company offers the excuse that aromatic digestive tablets are of such a nature that they cannot "be expected to test up to labeled strength." This argument cannot be accepted unconditionally because the firm is engaged in a professional, as well as a commercial enterprise. Scientific investigation has demonstrated beyond any doubt the irrationality, one might even say absurdity of such combinations of digestive ferments as go to make up the various brands of aromatic digestive tablets, and all chemists and manufacturing pharmacists are familiar with these facts. The excuse for manufacturing them is that there is a call for them. That is to say, in spite of the demonstrable absurdity of the combinations of pepsin and pancreatin, etc., physicians continue to call for, and to waste their patients' money on, these ridiculous mixtures. Pharmaceutical concerns that wish to continue to sell aromatic digestive tablets, even though the scientific men on their staffs know that the preparations are absurd and that the ferments that are put into them will, in all probability, destroy each other before they can reach the patient, should be made to date such products. After all, though, it is a question whether the physician who ignorantly prescribes aromatic digestive tablets is not more morally culpable than the pharmaceutical house that supplies what such physicians demand.

NO SPECIFIC "CURE" FOR INFLUENZA

The present epidemic, as was to be expected, has given rise to the publication in the newspapers of all kinds of "sure cures." Their number is legion, and they vary in character from those with a semiscientific basis to others with no basis whatever. Some could be classed under the term ridiculous. Many persons recommend certain methods of treatment from purely altruistic motives, others for financial gain. Almost all of the proponents of alleged specific methods are bombastically enthusiastic. Hyperenthusiasm applied to moral or esthetic ideals is a praiseworthy emotion, but as related to medical science is usually a delusion and a snare. The research worker should view his results with a cold, dispassionate conservatism, before considering publication with resultant harm to himself and the public. Many of the alleged cures and remedies now being recommended probably will do more harm than good. The United States Public Health Service, having been besieged with inquiries regarding this and that method of treatment, has issued a special bulletin in which it is emphasized that there is no specific cure for influenza yet known and that the chief reliance must be placed on good hygiene, good nursing and symptomatic treatment.

BARLEY WILL CONSERVE WHEAT

"Barley," says M. Hindhede,[1] the Danish exponent of economy in nutrition, "is too valuable as a human food to be used in these hard times as fodder for pigs or in the production of beer." This conclusion was based on extended dietary experiments on men in which barley, margarin, sugar, milk and fruit represented the range of variety in the food intake. The cereal was used mostly in the form of coarse groats, yet it was utilized almost as well as comparable coarse whole wheat bread; and doubtless a better milled or better cooked product would have shown even superior digestibility. The availability of the very coarse cereal used was by no means equal to that of the finest wheat bread or similar refined products, but its wholesomeness seemed to be beyond question. An exclusive diet of cereals is never ideal, whatever the source of the grain used. But many persons have depended so largely on wheat in the past that they fail to recognize the equivalent merits of its substitutes. We have already spoken a good word for barley in support of the well founded contentions of the U. S. Food Administration. Barley is extremely hardy, and is grown as far north as the Arctic Ocean in Russia and as far south as the Nile and the equator in eastern Africa. Its drought-resisting qualities make it particularly valuable as a crop in somewhat arid regions. Barley is believed to have been one of the first cereals used by man and is today probably the best of the substitutes for mixing with wheat in bread-making.

Medical Mobilization and the War

Government Purchase for Laboratory School at New Haven

The government has recently purchased the property of the Elm City Hospital Corporation, New Haven, and is using it for work in connection with the Yale Army Laboratory School and the medical side of the Chemical Warfare Service. All candidates for positions in the various base, field, and mobile laboratories overseas will be sent to New Haven for intensive training. About 400 men are enrolled and are under the command of Lieut.-Col. Charles F. Craig, M. C., U. S. Army. Work has been commenced on a temporary building on the New Haven Hospital grounds for the Army Laboratory School.

New Publication of Camp Wheeler Hospital

The United States Base Hospital at Camp Wheeler, Ga., has just begun the publication of a semimonthly, the *Camouflage,* devoted to the interests of the Medical Department. It is a twelve-page publication excellently printed, and with an artistic cover. The name, the *Camouflage,* seems particularly apt since the first issue contains several items taken from, and which were original in, the "Tonics and Sedatives" department of The Journal without credit. They are signed by Sarg. this and Sarg. that.

Honors Awarded

The Distinguished Service Cross has been awarded to Capt. George E. McGinnis, One Hundred and Tenth Ambulance Company, One Hundred and Third Sanitary Train, of Clarendon, Pa., who on "The night of August 9, with complete disregard of his personal safety made a reconnaissance under fire and located a line of evacuation for ambulances from Fismette, and on the morning of August 10, under shell fire personally repaired the bridge between Fismes and Fismette thereby making possible the evacuation of twenty-eight wounded men," also to Asst. Surg. Ogden D. King, U. S. Navy, Albemarle, N. C., attached to U. S. Marine Corps, "In action near the Bois de Belleau, June 9 and 10, in two successive days the regimental aid station in which Surgeon King was working was struck by heavy shells, and in each case demolished. Ten men were killed and a number of wounded badly hurt by falling timbers and stones. Under these harassing conditions this officer continued without cessation his treatment of wounded, assisting in their evacuation, and setting an inspiring example of devotion and courage to the officers serving under him."

Rehabilitation of Soldiers and Sailors

The federal board for vocational education has begun the work of placing disabled soldiers and sailors for reeducation, according to the *Vocational Summary* for October. The rehabilitation division of the board has opened offices, for the purpose of reeducating and placing disabled men, in seven different districts. District 1 comprises the New England States, except Connecticut; District 2, New York, New Jersey and Connecticut; District 3, Pennsylvania and Delaware; District 4, West Virginia, Virginia, Maryland and the District of Columbia; District 5, Florida, Georgia, North Carolina, South Carolina and Tennessee; District 6, Louisiana, Mississippi and Alabama, and District 7, Indiana, Ohio and Kentucky. Other districts will be created and offices opened as soon as the proper personnel can be obtained. In dealing with the disabled man the board expects to treat him throughout as a civilian needing advice and assistance, to approve his choice of occupation unless, after careful investigation, sound opinion shows it to be in the end not advisable to train him to meet the needs of the occupation he has elected, to urge him to make the most of his opportunity to overcome his handicap by taking thoroughgoing instructions, to help him to secure desirable permanent employment, and to keep in close touch with him after he goes to work.

Officers Needed in Sanitary Corps, U. S. Army

A communication from the office of the Surgeon-General announces that for the purpose of meeting the requirements of a considerably enlarged program of service, both in the Army camps in this country and with the American forces overseas, the Sanitary Engineering Section of the Sanitary Corps is in need of a number of officers of the following types: sanitary engineers of broad training and experience in water supply and its purification, sewerage and sewage disposal, and other engineering activities related to public health; engineers with practical experience in drainage and mosquito control operations; epidemiologists with good training in preventive medicine and qualified to institute and administer practical measures for the prevention or control of contagious disease; municipal health officers or sanitary inspectors with sound training in the fundamentals of sanitation and with a record of successful experience in handling men and in the sanitation of closely occupied areas, such as cities and industrial communities; water chemists and bacteriologists skilled in field and laboratory examination of water and with practical experience in water and sewage problems. The present and prospective work of this section will require the services of both commissioned and noncommissioned officers, and of a relatively small number of privates. Applications for information and for service should be made to the Surgeon-General, Washington, D. C.

VOLUNTEER PHYSICIANS FOR UNITED STATES PUBLIC HEALTH SERVICE

The Journal has published several announcements asking for volunteers for permanent work as acting assistant surgeons in the Public Health Service. In addition, the Public Health Service is in urgent need of physicians for temporary duty in connection with the influenza epidemic. This work is being organized by states in connection with the state boards of health. Physicians who wish to make themselves available for temporary emergency work at a salary of $200 per month and $4 per diem allowance for subsistence should communicate with the Surgeon-General, U. S. P. H. S., indicating their desire to serve, or communicate directly with the Public Health Service officer in their own state. A list of such public health officers follows:

Alabama—P. A. Surg. Robert Olesen, City Hall, Montgomery.
Arizona—Field Director O. Harry Brown, Supt. Public Health, Phoenix.
Arkansas—Asst. Epidem. J. C. Geiger, City Hall, Little Rock.
California—Surg. W. C. Billings, 76 New Montgomery St., San Francisco.
Colorado—T. D. E. E. Kennedy, Sec. State Board of Health, Denver.
Connecticut—Hdqrs. at Boston, Mass., State House, R. 167-C, Boston.
Delaware—A. A. Surg. J. W. Richards, c/o St. Bd. Health, Wilmington.
District of Columbia—Asst. Surg. E. S. Mustard, Webster School, 10th and H Sts., N.W.
Florida—Asst. Surg. O. H. Cox, State Bd. of Health, Jacksonville.
Georgia—Asst. Epidem. C. C. Applewhite, 78 Marietta St., Atlanta.
Idaho—Field Director E. T. Bower, State Health Officer, Boise.
Illinois—Senior Surg. J. C. Cobb, 4141 Clarendon Ave., Chicago.
Indiana—A. A. Surg. W. F. King, State Board of Health, Indianapolis.
Iowa—Asst. Surg. W. C. Witte, Box 912 (Telegrams U.S.P.H.S.) Des Moines.
Kansas—Collab. Epidem. S. J. Crumbine, State Health Officer, Topeka.
Kentucky—Surg. L. D. Fricks, 519 Custom House, Louisville.
Eastern Kentucky—Surg. John McMullen, P. O. B. Lexington.
Louisiana—Surg. C. M. Corput, Marine Hospital, New Orleans.
Maine—P. Asst. Surg Paul Preble, c/o State Health Officer, Augusta.
Maryland—A. A. Surg. C. Hampson Jones, State Dept. Health, 16 W. Saratoga St., Baltimore.
Massachusetts—State House, R. 167-C, Boston (Headquarters).
Michigan—Field Director R. M. Olin, Sec., State Bd. of Health, Lansing.
Minnesota—Collab. Epidem. R. M. Bracken, Sec. State Bd. H., St. Paul.
Mississippi—Collab. Epidem. W. S. Leathers, State Bd. H., Jackson.
Montana—Collab. Epidem. W. F. Cogswell, Sec. State Bd. H., Helena.
Nebraska—Field Director W. F. Wild, Com. of Health, Lincoln.
New Hampshire—State House, R. 167-C, Boston, Mass. (Hdqrs.)
New Jersey—P. A. Surg. W. L. Treadway, State Bd. Health, Trenton.
New Mexico—Surg. J. W. Kerr, Castenada Hotel, Las Vegas.
New York—Field Director Hermann M. Biggs, Com. of Health, Albany.
North Carolina—Prof. C. W. Stiles, State Board of Health, Raleigh.
North Dakota—Field Director C. J. McGurren, Sec. Bd. H., Devils Lake.
Ohio—A. A. Surg. E. W. Scott, U.S.P.H.S., State Bd. Health, Columbus.
Oregon—A. A. Surg. A. C. Seely, State Board Health, Portland.
Pennsylvania—P. A. Surg. W. F. Draper, State Dept. H., Harrisburg.
Rhode Island—(Hdqrs. Boston, Mass.) State House, R. 167-C, Boston.
South Carolina—P. A. Surg. C. V. Akin, State Bd. Health, Columbia.
South Dakota—Field Director Park S. Jenkins, Supt. Health, Wanbay.
Tennessee—P. A. Surg. R. C. Derivaux, State Bd. of Health, Nashville.
Texas—Surg. C. H. Gardner, State Board of Health, Austin.
Utah—A. A. Surg. T. B. Beatty, State Bd. Health, Salt Lake City.
Vermont—(Hdqrs. at Boston, Mass. State House, Room 167-C):
Virginia—Sc. Asst. W. L. Wood, State Board of Health, Richmond, Va.

Washington—A. A. Surg. T. D. Tuttle, c/o State Board of Health, or 930 Henry Bldg., Seattle.
West Virginia—A. A. Surg. Alston Maxwell, 16 Masonic Bldg., Charleston.
Wisconsin—Field Director C. A. Harper, State Health Officer, Madison.
Wyoming—Field Director C. Y. Beard, Sec. State Bd. H., Cheyenne.
Pennsylvania—Surg. Edward Francis, Armory, Chester, Pa.

The Twenty-Sixth Annual Meeting of the Association of Military Surgeons

The twenty-sixth annual meeting of the Association of Military Surgeons was held at Camp Greenleaf, Chickamauga Park, Ga., under command of Col. W. N. Bispham, October 14 to 16. The attendance (about 400) consisted of representative medical officers from the U. S. Army, U. S. Navy, and the Public Health Service. Among the papers presented were those of Lieut.-Col. George E. deSchweinitz, showing how eyes are saved and thereby limiting the number of cases of blindness. Conditions of the ear, nose and throat, whereby the hearing and sense of smell and taste were saved in many instances, were shown by Col. H. P. Mosher of Boston, and also by Col. W. J. S. Lyster.

The Surgeon-General's Office of the Navy was represented by Capt. George A. Lung, commanding officer, U. S. Naval Hospital, Brooklyn, who is in charge of the largest naval hospital in the world. To a large extent many of the members of the Marine Corps from the Chateau Thierry and Soissons sector are under his care. Captain Lung, as president of the organization, read a most instructive and interesting paper reviewing the history of the organization and holding forth some of the problems that would have to be presented to the medical officer at the end of the war.

Capt. F. S. Pleadwell, M. C., U. S. Navy, who was medical aide to the commandant of the Norfolk Naval District and for a year naval observer to the allied forces in Europe, presented a most interesting paper on hygiene and sanitation in which he described the improved conditions installed throughout Europe in an endeavor to make "our boys" have healthy surroundings. He described how their quarters were made habitable, and how diseases which were responsible for a large number of deaths during the Spanish-American War were entirely eliminated. Captain Pleadwell was elected third vice president.

Capt. F. T. McCullough, fleet surgeon of the Atlantic fleet, read a most instructive and intesting paper relative to the handling of our sick and wounded boys in their being transported from the other side to America.

Capt. J. A. Murphy of the Surgeon-General's Office described the importance of the work that is being carried on at Camp Greenleaf under Colonel Bispham, commanding, and its relation to the Navy and the work of the Navy while our troops are transported to Europe.

A most unusual and interesting demonstration was shown by Commander R. S. Bainbridge, M. C., U. S. Navy, in which he showed some moving pictures which have not as yet been shown in America until the present meeting, and demonstrating the advances made in restoring the cosmetic appearance of men who have extensive injuries to the nose, mouth, chin, and about the eyes. Many persons who would otherwise look hideous have had artificial face masks made out of copper netting treated with silver, and molded in such a position as to cover defects in the nose and other parts. Special details are completed by comparing the artificial face with a photograph before the injured went to war. Commander Bainbridge also gave a most interesting talk on the spirit of the Medical Corps, of the soldiers, and of the civilian population behind the battle lines. He described the not infrequent reinvigoration of elderly men, who are taking the places of many of the younger men who were killed in large numbers during the early part of the war.

One of the papers on surgical subjects was presented by Major F. H. Albee, M. C., which gave the importance of using the bone particles in the restoration of lost bone. The subject was beautifully illustrated with moving pictures.

On the afternoon of October 15 the entire command of Greenleaf was reviewed by Colonel Birmingham, president-elect of the association. On the same evening the delegates and visiting members witnessed a minstrel show which was staged for their entertainment. This entertainment was furnished by the enlisted personnel of Camp Greenleaf. A great many members remained until the close of the session, Wednesday evening, when they were entertained with an athletic exhibition, consisting of wrestling, boxing, etc., the music for which was furnished by the 120 piece Camp Greenleaf Medical Department Band.

At the business meeting several important amendments to the constitution were adopted, one of which admits to associate membership acting assistant surgeons of the Army, Navy and Public Health Service, and another provides for a sinking fund committee to consist of the president, treasurer, and three members selected from former presidents of the association. The following officers were elected: president, Col. Henry P. Birmingham, M. C., U. S. Army; vice presidents, Col. Joseph A. Hall, M. C., U. S. Army, Cincinnati (representing the National Guard); Asst. Surg.-Gen. John K. Kerr, U. S. P. H. S., and Capt. Frank L. Pleadwell, Medical Director, U. S. Navy; secretary-treasurer, Col. William J. L. Lyster, M. C., U. S. Army, and members of the sinking fund committee, Surg.-Gen. Rupert Blue, U. S. P. H. S.; Admiral William C. Braisted, Surgeon-General, U. S. Navy, and Col. Van R. Hoff, M. C., U. S. Army (retired). The selection of the next place of meeting was left to the executive council with power to act.

American Expeditionary Forces' Weekly Bulletin

The following paragraphs are taken from the *Weekly Bulletin of Disease*, dated September 23, issued for circulation among American medical officers in France:

PNEUMONIA

Septic pneumonia, due commonly to the *Streptococcus hemolyticus*, has appeared in virulent form in a dozen or more different and widely separated points in France. There has been a high mortality (from 20 to 40 per cent.), deaths occurring in many instances within twenty-four and forty-eight hours of onset of symptoms. The conflict between infection and resistance, once the symptoms are well declared, is apparently but little modified by any treatment provided.

Exhausted, driven, anxious men are easy prey to infection. The condition of the men when exposed to infection is of far greater importance than the care he gets after he is sick in bed. A man is entitled to at least the devoted care given to a horse. The man's resistance is largely at the mercy of his officers, and to them we must look for the greatest measure of prevention.

Here is what energetic and resourceful medical men are doing about the pneumonia situation in the A. E. F., through improvements in sanitation of environment and control of personal habits:

(From Headquarters, 32d Division, Office of Division Surgeon)

For the purpose of prevention and treatment, pneumonia will hereafter be regarded as a contagious disease by the medical personnel of this division.

If a case occurs during an inactive period or while in billets, the following will govern:

1. Send patient to hospital designated.
2. Report the diagnosis to this office by telephone or courier, giving name, number, company, organization, number of contacts and where they may be found.
3. The contacts will be segregated. The term "contacts" will be understood to mean all those who have been in close and more or less permanent relationship with the sick man and those who sleep in nearby and adjoining beds, those who work with him in kitchens, offices, and the like.
4. The surgeon will immediately make an inspection of quarters, reporting number of occupants, cubic feet of air, light, etc. He will arrange for a thorough cleaning and disinfection of the billet and institute efficient preventive measures, such as antiseptic treatment of the nose and throat of all contacts.
5. On arrival in hospital, the patient will be isolated, so far as practicable by screening or otherwise. Attendants will wear gauze masks over the nose and mouth and will be given the same treatment as other contacts.
6. One or more wards, as necessary, will be designated as pneumonia wards. No other cases will be admitted.
7. No visitors will be allowed, except when absolutely necessary.
8. Utensils, linen, etc., will be handled as with other contagious diseases.
9. Pneumonia, as with other respiratory diseases, is spread by careless expectoration and coughing (droplet infection). Effective regulations must be enforced for the prevention of infection by this means. Educate the men as to the dangers of careless expectoration.
10. Battalion surgeons will make frequent inspections of billets and inspections and examinations of men in order personally to know at all times the conditions under which

the men are living and their physical condition. The battalion surgeon who does not know the physical condition of the men at all times is *not* giving efficient service. The daily sick call does not give sufficient opportunity to know the true condition.

Pneumonia is a disease, the result of human contact. It is spread by overcrowding in billets, by exposure to cold and wet, by exhaustion, etc. See that the men have a reasonable air space in billets and that the billets are ventilated. Sleeping with heads placed alternately prevents men from coughing in each other's faces.

The effective strength of this division depends to a large extent on the earnest efforts of all medical officers to improve sanitary conditions. Where such efforts do not bring results, submit report to this office stating action taken, dates, and the names of responsible officers, in order that the matter may, if necessary, be brought to the attention of the commanding general.

(Headquarters, Hospital Center, Rimaucourt)

The commanding officer of each organization will report by memo to this office within two weeks after arrival in camp that each officer, nurse and employee of his organization can correctly recite the answers to the questions as given below:

Q.—What is the greatest danger to which you are exposed in France?

Ans.—Death from such diseases as meningitis, pneumonia, tonsillitis, influenza, measles and diphtheria.

Q.—How can I avoid this danger?

Ans.—1. By preventing comrades from coughing or breathing in my face.

2. By preventing comrades from spitting in and around buildings.

3. By preventing comrades from shutting up buildings so that the air may get close.

Q.—What else shall I do to avoid endangering my comrades?

Ans.—1. I will turn my head when I cough.

2. I will hold a handkerchief in my hand over my mouth when I cough.

3. I will keep my handkerchief and my hands clean at all times.

4. I will fix up a can in which men in my barracks can spit into a disinfecting liquid.

(Headquarters, Base Section No. 2, S. O. S.)

The following directions are given for the guidance of medical officers in the treatment of the disease (epidemic influenza and pneumonia) and to prevent its spread. The situation is serious and demands the utmost effort on the part of medical officers and thorough cooperation on the part of line officers.

(*a*) Early recognition of the first cases with their prompt and complete isolation.

(*b*) Every patient should be strictly confined to bed until symptoms have completely abated. Isolation should be maintained throughout convalescence.

(*c*) The bowels should be evacuated at the beginning of an attack, and liquid or light diet be given.

(*d*) In case of any spread of the disease in an organization, the organization should be quarantined; all pass privileges should be withdrawn, no troops should be sent elsewhere from an affected organization, and any new troops that are introduced into it while the disease prevails should be isolated so far as possible from the rest of the organization.

(*e*) It should be remembered that the disease is highly contagious, that it is probably most readily transmitted by the nasal, pharyngeal and bronchial discharges, especially in coughing, sneezing and spitting, but that it may also probably be transmitted by blankets, clothing, mess kits and other articles used by patients.

(*f*) Public gatherings, such as movie shows, concerts and dances, should be prohibited during an epidemic.

(*g*) The utmost efforts should be made to prevent overcrowding of the men in quarters during an epidemic. Where feasible, it is well to put men outdoors to sleep if necessary to prevent overcrowding.

(*h*) Medical officers are directed to report promptly to the chief surgeon of this base any indications of an incipient epidemic among the troops for which they are responsible.

(*i*) Reports from the French Service de Santé inform us that the disease prevails among the civil population in many localities, notably at Bordeaux, Arcachon, Tarbes, and Bayonne. Commanders of organizations in which the disease does not exist are warned against granting leave to any place where the disease is prevalent on account of the danger of such men introducing the disease into their organization on their return.

Evacuation or Transfer of Pneumonias.—Medical officers are warned against exposing pneumonia patients or patients with severe pulmonary disease with fever to the fatigue of transportation unless under urgent necessity for space for battle casualties. Complete rest in pulmonary disease is absolutely indispensable.

SPECIAL WARNING

Influenza is as contagious as measles and as dangerous. It is a dangerous disease by reason of the fatal complicating pneumonia. Isolate all cases of influenza, and if severe, hospitalize immediately. Examine daily all contacts for the earliest signs of the disease (pharyngitis, fever and conjunctivitis), and isolate promptly. Watch for the earliest symptoms of pneumonia. These are slight cyanosis, increased respiration, and a continuation of fever beyond the third or fourth day. The early signs of involvement of the lungs in bronchopneumonia may be slight and shown only by hyperresonance and scattered râles. It is imperative that all bronchopneumonia suspects should be removed from influenza wards and isolated separately. Beware of too early evacuation of influenza patients.

COMMISSIONS OFFERED AND ORDERS TO DUTY ON ACCEPTANCE

Alabama

To Army Medical School, Lieut. J. J. HALL, Oak Hill.

To Camp Joseph E. Johnston, Fla., Capt. O. J. BROOKS, Huntsville; Lieut. W. E. WARREN, Fort Payne.

To Fort Oglethorpe for instruction, Capt. R. A. SMITH, Brewton; Lieuts. E. H. WALKER, Birmingham; N. S. JOHNSON, Clanton; J. H. DODSON, Mobile.

Arkansas

To Fort Oglethorpe for instruction, Capt. O. MILLER, Fayetteville.

To Fort Riley for instruction, Lieuts. R. O. SMITH, Reyno; L. GARDNER, Russellville; E. D. BUTLER, Wilmar.

California

To Camp Cody, N. M., base hospital, for instruction, Capt. J. A. McNAUGHTON, Lieut. M. A. FRANK, Los Angeles.

To Camp Fremont, Calif., base hospital, Capt. W. O. MONTGOMERY, San Francisco; Lieut. J. W. DEWITT, Antioch. Base hospital, for instruction, Capt. E. A. KUSEL, Oroville.

To Camp Kearney, Calif., Capt. F. E. BROWN, Los Angeles; Lieut. E. E. DOTSON, Escondido. Base hospital, for instruction, Capt. J. S. GREEN, Oakland.

To Camp Lewis, Wash., Capts. M. M. ARMSTRONG, W. A. DUNTON, Los Angeles; Lieut. H. J. FORBES, Pasadena.

To Denver, Colo., Capt. J. B. FISH, San Leandro; Lieut. R. J. CARY, Livermore.

To Fort Oglethorpe for instruction, Capt. M. W. KAPP, San Jose; Lieuts. W. W. DUTCHER, L. E. WILSON, Los Angeles; E. C. BLACK, San Diego; E. F. HOLBROOK, San Jose.

To Fort Riley for instruction, Capts. R. N. SMITH, Los Angeles; R. O. SHELTON, San Diego; Lieuts. C. F. CRITTENDEN, Alameda; W. C. PRUETT, Oakland; F. R. MUGLER, San Francisco; R. L. HOGG, Saratoga; H. G. ROSENBERGER, Whittier.

To report to the commanding general, Hawaiian Department, Lieut. J. H. HURST, Santa Barbara; Western Department, Capts. A. A. MILLIKEN, Fort Jones; C. H. WALTER, San Jose.

To Sacramento, Calif., Mather Field, Capt. P. de OBARRIO, San Francisco.

To San Francisco, Calif., Letterman General Hospital, Lieut. L. DOZIER, Stockton.

Colorado

To Camp Lewis, Wash., base hospital, Capt. D. G. MONAGHAN, Denver.

To Fort Oglethorpe for instruction, Lieut. L. M. MAITLAND, Drake.

To Fort Riley for instruction, Capts. S. H. BELL, Montrose; W. LUCAS, Pueblo; Lieuts. R. L. DOWNING, Bayfield; G. F. LEE, Denver; C. H. TIDD, Telluride.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. J. A. MOREHOUSE, Idaho Springs.

Connecticut

To Camp Lewis, Wash., Lieut. W. E. COYLE, Waterbury.

To Camp Wheeler, Ga., base hospital, Lieut. C. K. STILLMAN, Mystic.

To Fort Oglethorpe for instruction, Capt. T. F. BEVANS, Waterbury; Lieuts. E. J. S. SCOFIELD, Danbury; F. E. FOLEY, H. J. GIAMARINO, H. W. GRODZINSKY, New Haven.

To Hoboken, N. J., Lieut. D. D. REIDY, Winsted.

To Plattsburg, N. Y., Lieut. E. T. GIBSON, Middletown.

Florida

To Camp Beauregard, La., Lieut. W. F. McGRIFF, Niceville.

To Camp Joseph E. Johnston, Fla., Lieuts. H. BYRD, Princeton; J. HALTON, Sarasota.

Georgia

To Fort Oglethorpe for instruction, Capt. J. P. PROCTOR, Athens; Lieuts. P. M. HOWARD, College Park; A. J. WHELCHEL, Cordele; D. J. BARTON, Hartwell; J. GERDINE, Jersey; C. S. FLOYD, Loganville; B. BASHINSKI, Macon; E. P. WHITE, Tignall.

Hawaii

To report to the commanding officer, Hawaiian Department, Capt. H. H. BLODGETT, Honolulu; Lieut. R. C. LICHTENFELS, Hana.

Illinois

To Camp Custer, Mich., Lieut. F. PHILLIPS, Arthur. Base hospital, for instruction, Lieut. H. R. KENNY, Chicago.

To Camp Grant, Ill., base hospital, Capt. L. B. PHELPS, Oak Park. *To examine the command* for nervous and mental diseases, Lieut. L. G. WRIGHT, Chicago.

To Camp Greene, S. C., base hospital, for instruction, Lieut. R. A. BUCKNER, Gilman.

To Camp Leach, D. C., Lieut. A. M. FROMM, Ramsey.

To Camp McClellan, Ala., Capt. W. H. GAMBILL, Centralia.

To Camp Pike, Ark., Lieut. I. F. FREEMMEL, Jacksonville.

To Camp Sevier, S. C., base hospital, for instruction, Lieut. E. ANDREWS, Chicago.

To Fort Oglethorpe for instruction, Capts. G. OSBORNE, M. M. PORTIS, Chicago; E. W. POTTHOFF, Oak Park; D. P. WIENS, Peoria; Lieuts. J. R BUCHBINDER, E. C. SKEMBARE, E. W. WHITE, Chicago; J. J. CONDON, Danville; W. R. GARDINER, Herrin.

To Fort Riley, Lieut. T. J. LAMPING, Chicago. For instruction, Capts. G. F. BRACKEN, C. L. CONROY, F. A. DAVIS, R. J. DUNN, H. K. GIBSON, J. H. REEVES, Chicago; C. E. HILL, East St. Louis; F. G. HALL, Galesburg; W. A. BALCKE, Pekin; Lieuts. C. A. JOHNSON, Barry; L. SMITH, Chapin; C. M. BERNTSEN, N. C. BULKLEY, D. D. BURNS, H. T. [illegible] DONOVAN, B. E. ELLIOTT, A. O. ELLISON, [illegible] FERGUSON, G. F. GATES, F. F. HOFFM[illegible] S. B. KOSITCHEK, J. H. KRAMER, S. OCHS, M. PENCHINA, Chicago; F. T. FITCH, Dunlap; G. O. HULICK, East St. Louis; W. T. COLLINS, I. J. GRANT, Freeport; D. S. BOLES, Herrin; H. T. KING, Joliet; T. S. EBAN, Mapleton; S. E. PARR, Ottawa; A. W. SLAUGHTER, Paris; W. M. AVERY, Pawpaw; W. E. FOSTER, Richmond; H. R. ROGERS, Rockford; R. E. VALENTINE, Tallula; R. G. EMPSON, Valmeyer.

To New Haven, Conn., Lieuts. M. D. REINHART, Chicago; W. J. WALLINGSFORD, Maywood. Yale Army Laboratory School, for instruction, Lieut. W. J. SCHOLES, Chicago.

To San Francisco, Calif., Letterman General Hospital, Capt. C. F. LARSON, Chicago.

Indiana

To Camp Shelby, Miss., base hospital, for instruction, Capt. H. G. FLEMING, Anderson.

To Fort Oglethorpe for instruction, Capt. W. B. PAGE, Goshen; Lieuts. F. G. GREEN, Bloomingdale; J. S. LEFFEL, Connersville; J. A. GARRETTSON, Indianapolis; E. J. EMMERT, Lawrenceburg; C. A. PAVY, Terre Haute.

To Fort Riley for instruction, Capts. C. W. YARRINGTON, *Gary;* G. A. PETERSDORF, Indianapolis; M. L. ARTHUR, Patoka; Lieuts. G. W. PIRTLE, Carlisle; B. G. DUPRE, Fort Wayne; A. M. KAN, Gary; E. F. STEINKAMP, Huntingburg; C. S. WISEMAN, Lakeville; H. G. LIND, Nineveh; J. H. GREEN, North Vernon; T. J. COLLINGS, Rockville; C. E. SAVERY, South Bend; W. A. BAGBY, Utica.

To New Haven, Conn., Capt. W. A. McBRIDE, Indianapolis.

Iowa

To Ann Arbor, Mich., State Psychopathic Hospital, Capt. E. E. HARRIS, Grinnell; for intensive training, Lieut. E. P. BENEDICT, Battle Creek.

To Camp Custer, Mich., Lieut. F. M. KEEFE, Clinton.

To Camp Dodge, Iowa, Capt. H. A. LINDSAY, Independence; Lieut. W. M. SHIRLEY, *Carroll.*

To Fort Oglethorpe for instruction, Lieut. L. F. TALLEY, Diagonal.

To Fort Riley for instruction, Capts. F. R. KING, Farmersburg; E. HENELY, Nora Springs; F. P. LEEHEY, *Oelwein;* E. R. *SHANNON,* Waterloo; J. M. SMITTLE, Waucoma; Lieuts. E. L. LAMPE, Bellevue; H. P. BENJAMIN, Council Bluffs; J. DUNN, Davenport; W. F. BRINKMAN, Des Moines; I. J. PASCOE, Harvey; G. MARIS, Hull; E. E. KIMMEL, Iowa City.

Kansas

To Camp Sherman, Ohio, base hospital, and for instruction, Capt. W. F. BOWEN, Topeka.

To Fort Oglethorpe for instruction, Capt. L. F. BARNEY, Kansas City.

To Fort Riley, Lieut. E. R. GHENEY, Gypsum. For instruction, Capt. R. J. HARLIN, Erie; Lieuts. R. B. McKINNEY, Augusta; W. R. SCOTT, Baxter Springs; W. ROBERTSON Caldwell; F. W. WHITE, Emporia; T. J. [illegible] TALBOT, Hoyt; F. D. LOSE, Madison; [illegible] R. E. TEALL, Palso; D. W. MELTON, [illegible], Salina; M. MEHRLE, Walnut; W. R. FISHER, Wichita.

Kentucky

To Camp Zachary Taylor, Ky., Lieut. A. J. DAVIDSON, Louisville. Base hospital, Major D. C. MORTON, *Louisville;* Capts. J. H. THORPE, Owensboro; G. F. DOYLE, Winchester; Lieut. W. L. SHANON, Newport.

To Fort Oglethorpe for instruction, Capts. J. R. MEEK, Covington; S. J. ROLLOW, Edgoten; J. C. LEWIS, Lexington; R. E. GRIFFIN, Owensboro; Lieuts. L. E. NICHOLS, Dawson Springs; W. A. ASHBECK, Gage; E. L. GATES, Herndon; E. E. EDWARDS, Irvine; W. E. DALE, Louisville; J. C. TUCKER, McDaniels.

Louisiana

To Camp Joseph E. Johnston, Fla., Lieut. W. K. EVANS, Lake Providence.

To Fort Oglethorpe for instruction, Lieuts. A. J. BABIN, G. J. HAUER, C. P. HOLDERITH, A. D. MOULEDOUS, New Orleans; S. B. WOLFF, Opelousas.

Maine

To Colonia, N. J., Capt. L. E. WILLARD, Saco.

To Fort Oglethorpe for instruction, Capt. D. A. McNALLY, Biddeford; Lieut. J. O. PIPER, Selon.

Maryland

To Fort Oglethorpe for instruction, Lieuts. R. C. HUME, Adamstown; H. B. AHTEY, C. E. CLARK, W. S. NIBLETT, M. E. SHAMER, Baltimore; W. L. BURNS, Cumberland; W. T. HAMMOND, Easton.

To Newport News, Va., Lieut. H. S. KUHLMAN, Jefferson.

Massachusetts

To Camp Devens, Mass., Lieuts. H. F. CURTIS, East Longmeadow; G. H. HICKS, Fall River. Base hospital, for instruction, Capt. A. P. GEORGE, Haverhill; Lieut. G. E. REYNOLDS, Pittsfield.

To Camp Gordon, Ga., base hospital, Lieut. A. A. CUSHING, Brookline.

To Camp Greene, N. C., to examine the command for nervous and mental diseases, Lieut. F. P. MOORE, East Norfolk.

To Washington, D. C., Surgeon-General's Office, for instruction, from Fort Riley, Capt. T. L. HARRINGTON, Milwaukee.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Passed Asst. Surg. J. H. LINSON, relieved at Boston, Mass., proceed to Washington for duty in the division of venereal diseases.

Asst. Surg. C. J. McDEVITT, report to Surgeon W. C. Billings for duty in suppression of influenza.

Asst. Surg. G. C. LAKE, proceed to Chicago, Ill., and other necessary points for observation in regard to vaccine against influenza and pneumonia.

Asst. Surg. CHARLES ARMSTRONG, proceed to Albany, N. Y., for duty in measures for the control of influenza.

Asst. Surg. R. C. WILLIAMS, relieved from further duty on Bureau of Mines car. *Proceed to Chicago, Ill.*, for duty in the control of influenza.

Prof. E. B. PHELPS, proceed to Chicago, Ill., and other necessary points in the vicinity of the Chicago Drainage Canal to assist in making plans for sewage disposal.

Acting Asst. Surg., ORLANDO DUCKER, proceed to Richmond, Va., for the duty in control of influenza.

Acting Asst. Surg. GEORGE HAYS, relieved at Chester, Pa., proceed to Columbia, S. C., for duty in influenza control.

Acting Asst. Surg., WILLIAM RICE, proceed to St. Louis, Mo., for duty at the Marine Hospital.

Dr. CAROLINE ROSENBERG, proceed to Wilmington, Del., for duty in influenza control.

Acting Asst. Surg. E. W. SCOTT, proceed to Columbus, Ohio, and other necessary places for duty in influenza control.

Acting Asst. Surg., FRANKLIN F. WALTERS, proceed to Newberry, S. C., for duty in influenza control.

Acting Asst. Surg. W. A. WILSON, proceed to necessary places in the State of New Jersey to organize venereal disease relief measures.

Phar. W. G. BEUCLER, proceed to Washington, D. C., for duty in the office of field investigations of industrial sanitation.

Sanitary Engr. A. F. STEVENSON, proceed to Framingham, Mass., for conference in regard to milk pasteurization.

Scientific Asst. GEORGE A. DECELL, proceed to Washington, D. C., for duty in compiling statistics relative to influenza and other communicable diseases.

Scientific Asst. SAMUEL SAUÑDERS, relieved at Brunswick, Ga., proceed to Washington, D. C., for duty in control of influenza.

Regional Field Director G. C. CAREY, proceed to Albany, New York City, Trenton, Wilmington, Baltimore and Washington and other points in the States of New York, New Jersey, Delaware and Maryland for duty in campaign of venereal instruction.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

Inroads of the War on School Medical Inspection Staff.—Soon after the entrance of the United States into the war, Dr. Prentiss Willson and Dr. Albert Ridgely, medical inspectors of schools, entered the Army Medical Service. During the past summer, Dr. John Thomas was commissioned and sent to camp, and during the past few weeks Dr. Joseph A. Murphy, chief medical and sanitary inspector of schools, was ordered to Camp Jackson, S. C., and Dr. H. C. Macatee, to duty at U. S. Naval Dispensary, Washington, D. C.

Curtailment of Medical Society Activities.—The Medical Society of the District of Columbia has long prided itself on maintaining meetings every week from October to May, always with interesting programs and good attendance. The securing of programs has become increasingly difficult owing to the absence of so many active workers now serving in the Army or Navy and to the increasing professional burdens of those physicians who remain. It has been necessary to abandon the meeting altogether during the influenza epidemic because of nonattendance, and it will probably be necessary to hold semimonthly meetings hereafter because of the dearth of scientific material. The society has remitted the dues of all members in active service with the Army and Navy, and in view of this reduction in the society's revenues it will be necessary to reduce the size or frequency of publication of the *Washington Medical Annals.*

Medical Care of Employees of the Navy Department.—A very large part of the increased clerical force of the Navy Department has been secured by the enlistment of both men and women as yeomen. These employees receive the regular Navy pay for their respective ratings and are given subsistence allowance in lieu of quarters and mess privileges. Being enlisted personnel, they are entitled to medical care and thus the Naval Dispensary has become an important adjunct to the Navy Department. The dispensary has recently removed to commodious quarters near Seventeenth Street and New York Avenue N.W., within easy walking distance of the various buildings housing the Navy Department. There are departments for internal medicine, minor surgery, gynecology, ophthalmology and otolaryngology, dentistry, and a very complete pharmacy. Enlisted men requiring hospital care are sent to the Naval Hospital, while enlisted women are sent to the Georgetown University Hospital under a contract arrangement. The dispensary is under the command of Capt. J. B. Dennis, M. C., U. S. Navy.

Influenza Epidemic Abating.—Washington is emerging from the influenza epidemic as from a bad dream. As is the common experience, the last week in September ushered in the disease and the last week in October finds little to do but clear up the wreckage of the storm. The epidemic found the community totally unprepared to cope with it; the depleted medical profession was unable to meet the situation fully and quickly became further depleted by illness of the doctors themselves; four physicians died, Drs. William E. Turton, Thomas Miller, Jr., Thomas B. Kramer, and Thomas S. D. Grasty, all of these having quickly fatal pneumonia. The local hospitals broke down during the first ten days of the epidemic, partly because overcrowded, but mainly because the nursing staffs suffered so severely from the disease. The Medical Society of the District of Columbia last spring realized the situation that an epidemic would create in this city and urged that a temporary hospital for the civilian population be provided; this recommendation being based on the fact that the population of Washington has been suddenly increased by nearly 150,000, mostly war workers, and that the majority of these people are living as lodgers without the most elementary necessaries to cope with an illness. Nothing came of this suggestion, but the present emergency made the need most apparent and the Public Health Service has established a large hospital for the treatment of influenza and this hospital has done a most important work. It is hoped that it may be maintained during the continuance of the war; for its value has already been amply demonstrated. The measures taken to combat the disease were: collaboration between the U. S. Public Health Service, represented by Dr. H. S. Mustard, and the local health department; the declaration of the District of Columbia as a sanitary zone; making influenza a reportable disease and requiring the segregation of persons suffering with it; closing of schools, churches, theaters, and other places of public assemblage; liberal placarding in streets and public buildings and grounds of information and advice regarding the mode of spread of the disease; the establishment of centers under the Public Health Service where immediate medical and nursing assistance could be obtained. In spite of all this the impression is current that the epidemic has simply burnt up all the available susceptible fuel and has passed on to new areas.

GEORGIA

Returns from France.—Major Edward C. Davis, formerly of Atlanta, and organizer of the Emory Unit of the ambulance service, is expected home from France in a short time.

Personal.—Dr. Jarrett W. Palmer, Ailey, was elected president, Dr. Alfred F. White, Flovilla, vice president, and Dr. Charles T. Nolan, Marietta, secretary-treasurer, of the Georgia State Board of Medical Examiners, at its meeting held in Atlanta, October 9.——Dr. Ferdinand N. Ware, Thomson, is reported to be critically ill as a result of a cerebral hemorrhage.

ILLINOIS

Arrest Illegal Practitioner.—Milton A. Chaiken of Joliet was arrested by the Department of Registration and Education of the State of Illinos for writing prescriptions and signing thereto the name of a licensed physician. He was fined $75 and cost on one charge. Six more charges against him are pending.

Chicago

Tuberculosis Institute.—At the meeting of the executive committee of the Chicago Tuberculosis Institute, held October 24, Dr. Herbert W. Gray was unanimously elected attending physician for the Edward Sanatorium, Naperville. Dr. Gray will also examine all applicants for admission to the institution at his office in Chicago.——Dr. Ethan Allen Gray still continues as consultant to the Edward Sanatorium. The Fresh Air Hospital and the Edward Sanatorium have entered into close cooperation, to the great advantage of the patients and institutions.

Fines and Imprisonments.—Judge Edmund Jerecki of the Municipal court, October 23, had arraigned before him four druggists and three physicians for alleged violation of the state medical practice act. "Dr." Jacob Bond is said to have been fined $200 and costs, on the charge of two complaints, and to have been sent to Bridewell on account of inability to pay the fine; "Drs." Julian Portes and Lorenz Girmhuber were said to have been fined each $25 and costs. and four druggists, charged with employing unlicensed men as registered pharmacists, were fined court costs.

INDIANA

Hospital Notes.—Plans are being completed for a hospital in Terre Haute, adjoining the Terre Haute Hospital to accommodate at least 100 patients. It is stated that this building is to be used for the care of invalided soldiers.——The west wing of the old City Hospital, Indianapolis, has been remodeled at a cost of $3,000. This wing will be used for contagious diseases only.——The Methodist Episcopal Hospital, Indianapolis, has placed one of its buildings in use as an influenza hospital.

Personal.—Dr. U. Willard Reed, Topeka, suffered a slight cerebral hemorrhage recently.——Dr. Edwin W. Dyar, Ossain, was operated on in the Lutheran Hospital, Fort Wayne, for appendicitis, October 21, and is reported to be doing well.——Dr. Carl L. Souder, Columbia City, was operated on in the Lutheran Hospital, Fort Wayne, October 19, for sinusitis.——Dr. Joseph N. Jerome has been appointed city health officer of Evansville, to succeed Dr. William E. Barnes, who has entered the military service.——Dr. Edmund C. Hack, Pence, is under treatment at the Lakeview Hospital, Danville.——Dr. Leo W. Roller, North Manchester, has accepted a position as city physician of Cleveland, Ohio.

KANSAS

Personal.—Dr. Alfred F. Yohe, physician at the Federal Penitentiary, Leavenworth, for nearly thirteen years, a member of the federal parole board, has resigned and has been succeeded for the time being by Dr. Jacob L. Everhardy.——Dr. Thomas J. Carter, Wichita, has been elected president of the Friend's Board of Kansas.

MARYLAND

Personal.—Dr. J. Knox Insley of Baltimore, who has been seriously ill with influenza that developed into pneumonia, is reported, the city health commissioner has partially lifted the Mason Knox, Jr., has returned to his home in Guilford, after a year spent in the Children's Bureau of Civilian Relief Work of the American Red Cross.

Volunteers of America Close Hospital.—After successfully conducting an emergency hospital at the headquarters of the Volunteers of America for the treatment of homeless sufferers from influenza and pneumonia, Capt. John Logan has announced that his hospital is closed, after having been in operation eleven days. During that time thirteen patients died, while thirty-five were discharged as cured.

Influenza Ban Lifted.—Owing to the great decrease in the number of deaths from influenza, as well as of new cases reported, the city health commissioner has partially lifted the ban which has been in effect for about two weeks. Unless there is another outbreak of the epidemic, the public schools, private schools, and colleges will be opened by the middle of the week. The ban has been entirely lifted on places of public worship, while it is partially lifted for department stores, theaters and motion picture parlors. The ban on saloons, cafés, retail liquor stores and nonessential assemblages is still existing. According to the official records at the health department, yesterday, there were 115 deaths reported, where influenza and pneumonia were given as the cause. There were also 257 new cases of influenza, as compared with 136 deaths and 304 new cases for a similar period for the day before. The total number of deaths from all causes announced for this period of time was 150 as compared with 171 for the period of twenty-four hours immediately preceding. The conditions throughout the state were reported by Dr. C. Hampson Jones, Baltimore, of the state board of health, as greatly improved and there were signs of an appreciable abatement in the epidemic.

The Baltimore Fund.—The trustees of the Baltimore fund have made a report on the first year's work on this fund, which was founded in April, 1917. During the year it received pledges amounting to $700,054.95, cash total, $323,495.90, and paid out $280,011.32, for free local charity [illegible] Baltimore Chapter of the Red Cross. [illegible] $12,942.47 was paid to the Baltimore [illegible] ross for home service, that is to say, assistance to families of Baltimorians in the Army and Navy. For the work devoted to babies and the Babies' Milk Fund Association, $20,273.16 was appropriated. To the Federated Charities for the relief of family distress, $95,997.12 was expended. The Friendly Inn Association recorded 9,933 "service days" for 710 men, provided 15,401 night lodgings, and 35,133 meals. For restoring a family life to children [illegible] $35,944.16 was appropriated to the Henry Watson Children's Aid Society. The Instructive Visiting Nurse Association expended $10,030.99 of the fund, visited 11,292 new patients, and made a total of 56,939 visits. To the Prisoners' Aid Association $13,991.64 was appropriated. Among other agencies in which the trustees of the Baltimore Fund are interested are the Maryland Tuberculosis Association, the Social Service Corporation, the Boy Scouts of America, Public Athletic League neighborhood work for which $36,138.17 was appropriated. For the problems of mental disorders and of feeblemindedness $3,353.49 was appropriated. For the Mothers' Relief Society, which gives medical care for poor mothers, $2,608.87 was appropriated. The trustees appropriated $2,135.03 to the Travelers' Aid Society. The Alliance of Charitable and Social Agencies, to unify and coordinate efficiency, economy, and cooperation in social work was given $15,692.95.

MINNESOTA

Personal.—Dr. Arthur E. Nichols, St. Paul, medical inspector in the state health department, has been appointed director of school hygiene to succeed Dr. William J. Little.

Southern Minnesota Physicians to Meet.—The annual meeting of the Southern Minnesota Medical Association will be held at Mankato, November 25 and 26, under the presidency of Dr. E. Starr Judd, Rochester.

Memorial to Wesbrook.—The faculty of the Medical School of the University of Minnesota, Minneapolis, has adopted a memorial to its former dean, Frank Fairchild Wesbrook, M.A., C.N., M.D., whose death was noted in The Journal of October 26, page 1428, bearing testimony to his qualities as a scientist in medicine, as a leader and administrative officer, and as a councilor and friend.

NEW YORK

New York City

Personal.—Dr. George H. Chaffee, who practiced medicine for many years in Brooklyn, has removed to Binghamton.——Mr. Robert E. Cusack has brought suit in the supreme court against Dr. Robert T. Morris for $250,000 damages, charging him with having removed surreptitiously a part of his body during an operation and engrafted the same on the body of an unnamed person. Dr. Morris declares that he operated on Cusack skilfully and successfully for a double hernia and that the allegations are without foundation.

Commission to Study Influenza.—Governor Whitman has appointed a commission to study and report on the cause prevention and treatment of influenza. Among those asked to serve are the Surgeon-Generals of the Army, Navy and Public Health Service; Dr. Rufus I. Cole of the Rockefeller Institute; Dr. Walter B. James, president of the New York Academy of Medicine; Dr. Hermann M. Biggs, New York State Commissioner of Health, and Dr. William H. Park, director of the research laboratories of the New York City Department of Health.

Influenza on the Decrease.—Reports from the health department, October 25, show that the epidemic of influenza is on the wane. A smaller number of cases are being reported and the number of discharges from the hospitals is exceeding the number of admissions. Since the health department began recording epidemic figures about 90,000 cases of influenza have been reported, with 5,984 deaths therefrom. The figures tabulated by the New York State Department of Health show the total number of deaths in the state, exclusive of New York City, for the first twenty-two days of October, as a result of the influenza epidemic, were 4,543, of which 3,313 were attributed to influenza and 1,230 to pneumonia. To the above date 96,110 cases of influenza have been reported in the state outside of the city of New York.

PENNSYLVANIA

Hospital News.—The Ellwood City Hospital, August 12, dedicated its new home which cost upward of $35,000.——The physicians of Bethlehem have purchased the Weiss property on East Broad Street for $26,500, and will alter the residence for hospital purposes.

Personal.—Dr. C. M. Richert of Millersville and Harrisburg has been appointed associate chief medical inspector of the state board of health.——Dr. Walter F. Donaldson, Pittsburgh, has been elected treasurer and also director of the Allegheny County Medical Society, to fill the unexpired term of Dr. William C. Bryant, who has entered the service

Influenza in Coal Regions.—Figures from the Anthracite Bureau of Information indicate that there is danger that the 1,000,000 tons gain in the mining of hard coal so far this year over the output of last year may be lost if the epidemic of influenza is not quickly checked. No section of the country has been so hard hit by the epidemic as the southern anthracite district, embracing Schuylkill and Northumberland counties. Reports show that since the epidemic broke out, October 4, there have been 2,200 deaths in these counties, one in every 145 of population. In Schuylkill County there are more than 1,500 orphans and 500 in Northumberland. As a result of the disease in Minersville, with a population of 6,000, there are 200 orphans. A peculiar feature is the fact that the epidemic was particularly virulent in the southern anthracite fields while the northern was not nearly so badly affected. In Wilkes-Barre there have been only fifty deaths. In Hazleton, October 26, there were 1,500 cases in the town; and 2,500 in the surrounding country. In Scranton up to October 25 from the beginning of the epidemic, October 5, there have been 4,250 cases reported, with 239 deaths. A detachment of more than 100 medical officers from Camp Crane, Allentown, have been in the region for ten days but now are gradually being withdrawn. According to reports to the state health department, October 26, the epidemic of influenza was rapidly growing worse in the southern bituminous coal fields and in Somerset County.

Philadelphia

Personal.—Drs. James M. Anders and L. Webster Fox have been elected trustees of the Polyclinic Hospital.——Dr. Charles J. Hatfield, who has served for the last four years as executive secretary of the National Tuberculosis Association, has been made managing director.——Dr. Luther C. Peter was elected secretary of the American Academy of Ophthalmology and Oto-Laryngology at its meeting in Denver, August 5 and 6.

Quarantine Lifted.—Dr. Benjamin F. Royer, Harrisburg, acting commissioner of health, telegraphed Dr. Wilmer Krusen, director of health and charities, that the ban might be entirely lifted, October 30. Although church services are to be permitted, no public funerals will be permitted, in fact the same regulations must govern funerals as are observed in cases where death has resulted from diphtheria or scarlet fever. The deaths from influenza and kindred diseases for the last six weeks have been as follows:

Week ended	Influenza	Pneumonia	Broncho-pneumonia
September 20	8	17	15
September 27	73	44	32
October 4	399	225	78
October 11	1,797	687	251
October 18	2,953	1,199	446
October 25	1,839	776	406
Totals	7,069	2,948	1,228

RHODE ISLAND

Fiske Fund Prize Essay.—At the annual meeting of the Rhode Island Medical Society, June 6, the trustees of the Fiske Fund proposed the following subject for the prize essay for 1919: "Recent Classification and Treatment of Pneumonia." The prize for the best essay is $200. The conditions of the competition are that each competitor must forward to the secretary of the trustees, on or before May 1 of the year of the competition, a copy of his dissertation with a motto, accompanied by a sealed letter with the same motto on the outside and the name of the competitor on the inside; the successful competitor must transfer to the trustees all his right, title and interest in the essay for the use and benefit of the Fiske Fund before he will receive the amount of the premium. The unsuccessful competitors may have their essays returned. The trustees are Drs. Gardner T. Swarts, John M. Peters and Jesse E. Mowry, all of Providence. Dr. Peters is secretary.

VERMONT

Personal.—Dr. Daniel J. Nolan, Burlington, who has been seriously ill with pneumonia, is reported to be convalescent.

Poliomyelitis.—The bulletin of the Vermont State Board of Health for the quarter ending September, 1918, is devoted almost wholly to a complete analysis of poliomyelitis as it occurred in the state in 1916 and 1917. The article is by the late Dr. Charles S. Caverly, Rutland, president of the state board and contains much valuable information in regard to the disease, the manner in which it was handled and the results.

CANADA

New Hospital.—The Salvation Army has purchased a private residence in Windsor, Ont., and is converting it into a general hospital. A campaign is being conducted to raise $32,000.

Personal.—Lieut.-Col. Harold C. Parsons, Toronto, who returned from overseas a short time ago, is now working with the committee inspecting Canadian military hospitals.——The following Toronto physicians have been assigned to duty at Basingstoke Hospital, England: Drs. Oliver R. Maybee, Norman T. MacLaurin, Charles W. Clark, Hanna and Robinson.——Col. John W. S. McCullough, Toronto, chief medical officer of health, Ontario, was requested to take charge of the medical unit to Serbia, but the Ontario government considered his services of more worth to the province in his present capacity.——Capt. Leroy J. Snider, Toronto, who was in Mesopotamia for some time, has been reported wounded.

GENERAL

Malaria Meeting Postponed.—On account of the prevailing epidemic of influenza the meeting of the national malaria committee at Asheville, N. C., November 11, has been indefinitely postponed.

Public Health Officers' Reserve.—Legislation authorizing the establishment of an officers' reserve in the United States Public Health Service, was completed, October 21, by the adoption of the conference report to the Senate. The bill is now in the President's hands.

New Tri-State Officers.—At the forty-fifth annual meeting of the Northern Tri-State Medical Association held in Fremont, Ohio, October 8, the following officers were elected: Dr. George V. Brown, Detroit, president; Dr. Charles C. Terry, South Bend, Ind., vice president; Dr. George W. Spohn, Elkhart, Ind., secretary, and Dr. Joseph A. Weitz, Montpelier, Ohio, treasurer.

Influenza.—From most sections of the country by the end of the month the epidemic was reported to be on the wane. In some communities more or less distant from the large centers of population and off the main lines of travel the disease was only beginning to show itself, or had not yet reached its height. It was present, however, in every state in the Union, as confirmed by reports to the Public Health Service.

Association Meeting Postponed.—A letter from the president, chairman of the council and business manager of the Southern Medical Association, under date of October 15, announces postponement for a year, of the twelfth annual meeting of the Southern Medical Association, which was to have been held at Asheville, N. C., November 11 to 14, on account of the widespread epidemic of influenza. The papers which were to have been read will be published during the coming year in the *Southern Medical Journal.*

Anesthetists Hold Meeting.—At the annual meeting of the Inter-State Association of Anesthetists held in Indianapolis, September 26, the following officers were elected: chairman, Dr. Jacob J. Buettner, Syracuse, N. Y.; vice chairman, Dr. William J. Jones, Columbus, Ohio; secretary-treasurer, Dr. F. Hoeffer McMechan, Cincinnati, and directors, Drs. Isabella C. Herb, Chicago; B. H. Harms, Omaha; Henry F. Becker, Danville, Ill.; George B. Winter, St. Louis; Louis H. Maxson, Seattle, and W. F. Dramburg, Milwaukee.

Railway Surgeons Elect Officers.—At the annual meeting of the American Association of Railway Surgeons, held in Chicago, October 16 to 18, the following officers were elected: president, Dr. John P. Kaster, chief surgeon of the Santa Fe Railway, Topeka, Kan.; vice presidents, Drs. James M. Miller, Villa Grove, Ill.; Charles P. Frantz, Burlington, Iowa, and John P. Lord, Omaha; secretary, Dr. Louis J. Mitchell, Chicago (reelected); treasurer, Dr. Henry B. Jennings, Council Bluffs, Iowa, and executive committee, Dr. Clarence W. Hopkins and Guy G. Dowdall, both of Chicago.

Refilling of Narcotic Prescriptions Temporarily Permitted.—Owing to the epidemic of influenza the provisions of Article 11 of Regulations No. 35 prohibiting the refilling of narcotic prescriptions have been modified as follows: *Prescriptions calling for morphin, codein or heroin, which are written by registered practitioners for patients suffering from Spanish influenza and any pulmonary or bronchial affections, may, until further notice, be refilled, provided that at the time of issuance by physicians instructions are noted in the body of such prescriptions, "Repeat if necessary," and the druggist filling and refilling the same shall note thereon each and every date on which such prescription is refilled.*

New Officers of Southwestern Association.—The thirteenth annual meeting of the Medical Association of the Southwest was held in Dallas, October 14 to 17. Oklahoma City was selected as the next place of meeting and the following officers were elected: president, Dr. Matthew M. Smith, Dallas; vice presidents, Drs. Robert L. von Trebra, Chetopa, Kan.; Oscar B. Hall, Warrensburg, Mo.; Frank W. Jelks, Hot Springs, Ark.; Foster K. Camp, Oklahoma City, and secretary-treasurer, Dr. Fred H. Clark, El Reno, Okla. (reelected). It was decided hereafter to publish the journal of the association in Oklahoma City instead of El Reno, and Dr. Everett S. Lain, Oklahoma City, was selected as the editor-in-chief, pending the return of Dr. Fred H. Clark, who is now in the military service.

FOREIGN

School Inspection.—The minister of public instruction in Spain has obtained from the king a decree establishing medical inspection of schools in Madrid and Barcelona.

Scarcity of Camphor.—A notice in the *Correspondenz-Blatt* warns that the wholesale dealers in Switzerland have long been entirely out of camphor, and that it behooves all to save what supplies are on hand for indispensable uses, as in camphorated oil, and not waste it in liniments, etc. A similar warning has been sent out by the national public health service in Norway, specifying bismuth as well as camphor as requiring the extremest economy in use.

Deaths in the Profession Abroad.—Dr. **Paul Lucas-Championnière** of Paris, director of the *Journal de médecine et de chirurgie pratiques.*——Dr. **M. Holmboe**, for twenty-five years chief of the national public health service of Norway, aged 66. He has published much on scientific and administration topics, and was the leader in the movement which resulted in 1900 in the notification of tuberculosis. Also in the transformation of the civilian medical service, which culminated in the law of 1912.——The *Siglo Medico* mentions the death of Prof. **G. Gaffky** of Berlin, who succeeded Koch as director of the Institute for Infectious Diseases, aged 68.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

For the Prevention of Blindness.—Following the meeting of the Fifth National Medical Congress in Mexico, a National Committee for the Prevention of Blindness has been founded, with Dr. J. Joaguin Izquerdo as secretary.

Influenza in Cuba.—The *Revista de Medicina y Cirugia* of Havana confirms the news item that the Spanish steamer *Alfonso XII* had 800 cases of pneumonic influenza on board, and there had been twenty-six deaths when it arrived at Havana. The epidemic has spread over the entire island, and there have been so many deaths, especially at Camagüey, that the people are much alarmed.

Reciprocity Between Peru and Uruguay.—The *Reforma Medica* of Lima gives the text of the diplomatic agreement between Uruguay and Peru for reciprocity in respect to academic credits in the liberal professions between the two republics. Not only the higher institutions of learning but the preparatory schools are thus enabled to receive students from the corresponding schools of the other country. The students are to matriculate and pay the same and have the same facilities for laboratory and similar work as the native students in each of the two states. The *Reforma* hails the new convention as "another link in the chain uniting the continent in intellectual Americanism." The reciprocity agreement is to remain in force for a year after either one of the contracting parties expresses a desire to withdraw. It is signed by the two plenipotentiaries appointed by the presidents of the two republics for the purpose, and is to be ratified by the respective governments.

CORRECTION

No Infantile Paralysis in Alfred, N. Y.—We are informed by Capt. D. C. Main, M. C., that the item which appeared under "Medical News" in The Journal of October 26, stating that seventy-seven mild cases of infantile paralysis had appeared in Alfred was incorrect. The newspaper item from which this note was taken probably referred to some mild cases of influenza. Alfred is the site of Alfred University, New York State School of Agriculture. This school has been chosen for a corps of the S. A. T. C., and has had a very low infection and death rate in the influenza epidemic. There has been no infantile paralysis in or near the village.

CUBA LETTER

Havana, Oct. 15, 1918.

The Epidemic of Influenza

The Department of Sanitation has been forced to take steps against the epidemic of influenza that has so rapidly spread throughout the republic. We have not, as yet, accurate statistics as to how many cases have occurred in the island, but many thousands have been reported. In Camagüey, where the epidemic seems to be most severe, 1,200 cases are known to exist at present and many have died of pneumonia; physicians and nurses have been sent from Havana to help the physicians of Camagüey and to establish prophylactic measures; all theaters have been closed, all public gatherings forbidden, and confinement of cases has been declared obligatory.

The Society of Clinical Studies

The Sociedad de Estudios Clinicos, September 30, elected new officers for the year 1918-1919. Dr. J. A. Presno was reelected chairman and Dr. L. R. Molina was reelected secretary.

The Medical Press Association

The Asociación de la Prensa Medica de Cuba elected new officers at the September meeting. Drs. J. F. Arteaga and J. B. Pons were elected president and secretary, respectively.

New Medical Journal

Dr. Matias Duque is the editor of the new monthly, *Medicina Cubana,* published in Havana and devoted to general practice.

Personal

Dr. R. P. Vento has been appointed professor of physiology at the University of Havana.

Dr. R. Menocal has been commissioned by the government to represent Cuba in the Congress of American Physicians and Surgeons.

BUENOS AIRES LETTER

Buenos Aires, Sept. 6, 1918.

Typhus in Northern Argentina

The commissions sent by the Public Health Service to northern districts have established the presence of typhus in several parts of the provinces of Salta and Jujuy, in the extreme north of the country, close to the border of Bolivia. It has been ascertained that the disease has been endemic there for some time, but in a milder form than at present. This endemic seems to be restricted to the poorest and most remote mountain regions of those provinces, small villages with scarcely any communication with the cities.

A number of villages were found affected by the endemo-epidemic; at Molinos, for example, with 200 inhabitants, 116 were found sick with typhus and 17 had died. It is believed that the low mortality, which averages from 10 to 20 per cent., is due to a relative immunization from previous attacks, but it is possible that the virulence is attenuated. Research is under way with guinea-pigs, and an antiserum is being prepared. It is almost certain that the disease will remain localized as the means of communication with more populous centers are so restricted. The governor of Jujuy has appealed for aid to the national government, which has promised to send a barracks hospital with personnel and equipment.

South American Conference on Hygiene, Microbiology and Pathology

In October the second conference of this kind is to convene at Rio de Janeiro. Drs. Miguel Couto and Carlos Chagas are to preside. The microbiologists and pathologists of the whole of South America have been invited to take part. The Argentine Departamento Nacional de Higiene is to send a delegation which will include Drs. Vidal, Cazes Itigoyen, Kraus, Carbonell, Roffo, Houssay and Sordelli. At the same time as this conference, is to be held the eight Brazilian Medical Congress to which several Argentine physicians have been invited, among others, Drs. A. Alfaro, Houssay and Mazza.

Sugar Treatment of Tuberculosis

The research in this line by the Italian, Professor Lo Monaco, has attracted much attention on account of the wide publicity given to it by the lay press. Many physicians have been giving a trial to this method of treating tuberculosis with hypertonic solutions of sugar. They have tried it also in whooping cough. The results have not been published as yet, but it may be announced in advance that, in whooping cough, no success has been realized. In respect to tuberculosis, the best result achieved has been a reduction in the amount of expectoration, and this result has been frequently realized.

University Notes

Dr. J. L. Llambias, *profesor suplente* of pathologic anatomy, has been appointed regular professor of this branch of study in the medical department of the University of Buenos Aires. This appointment has aroused some discussion as he is the *intendente municipal* of the city, and although second in the *terna* was yet nominated by the chief executive, as the universities are state institutions.

The vacancies left by the death of Dr. Ayerza and the retirement of Dr. Molina, have to be filled by the chief executive.

The Facultad de Medicina has proposed for the chair of clinical medicine, Dr. M. Castex as the first choice, Dr. J. J. Viton as the second, and Dr. R. Bullrich as the third choice. For the chair of obstetrics, the choice is, first, Dr. A. Enriquez; second, Dr. P. Ramos, and third, Dr. Tronge.

The Academia de Medicina has opened the lists to fill a vacancy in the section of clinical medicine and one in the surgical section.

LONDON LETTER

London, Oct. 3, 1918.

Physicians in Parliament

It is recognized that our social fabric will be profoundly modified after the war, which will leave nothing the same as it was before. As has been explained in previous letters, the medical profession is looking forward to considerable changes, among which is the establishment of a ministry of health. The need of representation of the profession in Parliament is also felt. A crowded meeting has been held in London, with Sir Henry Morris, president of the Royal Society of Medicine, in the chair, to elect an executive committee to select suitable members of the profession willing to stand as candidates for Parliament. Sir Henry Morris pointed out the great attention now given to public health questions in Parliament and the anomaly that such matters as the endowment of pathologic research should be entirely in the hands of lawyers, shipowners, brewers and other politicians with no medical knowledge. Dr. Addison, minister of reconstruction, moved the resolution. It may be pointed out that he is the only member of the medical profession who ever attained the rank of cabinet minister. Before he entered politics he was not a practicing physician but a lecturer on anatomy. He moved that "in the interests of the national health it is essential that the considered views of the medical profession should be voiced by representative medical men in the House of Commons." He said that there was a wealth of opportunity for advice open to men of the right type and training in matters affecting the homes of the people. In these matters there would be a growing need for the assistance of men who had had the advantage of medical knowledge and practice. The war had revealed what great things could be done in the prevention of sickness and injuries. If medical science had not progressed since the days of the South African War we might by now have had a million or more cases of typhoid, instead of a mere handful. But far beyond those things we found, increasingly, that a similar guidance, gathering continually the results of experience and research, was needed with regard to the events of daily life. The prime minister had said the other day that we could not expect to run an A 1 empire on a C 3 population (referring to the extreme classes in the grading of recruits for the army). It would be true to add that we could not expect to get an A 1 population out of C 3 homes, habits, workplaces or conditions. As a first step it was necessary to bring together the assortment of different departmental responsibilities in health matters, and to secure that the thinking out and development of a systematic health policy, commensurate with urgent national needs, should be made the duty and responsibility of a definite body of men. We should and must be the victims of sporadic disjointed, and often conflicting effort until this was done. The Ministry of Health would not itself be a health service. It would be its duty to secure the development and administration throughout the country of adequate health service. It was an essential part of the project that there should be connected with the ministry certain consultative councils, of which one must be medical, whose duty it would be to advise on proposals, to make suggestions, and to afford the best advice that it could give or obtain. In the budget of 1914, Mr. Lloyd George had provided $5,000,000 toward improved health services, but the war interrupted the scheme they then had in their minds. Recent experiences would suggest improvements. Developments of adequate health services would need the good will and help of physicians as well as of those familiar with the problems of local government, insurance and other important services, and if the subject was approached in a proper spirit he was confident that they would be obtained. Those who were concerned with the business of government and administration, whether central or local, would have much to learn and would derive much help from such counsel. Physicians would also learn a good deal. The C 3 class and all that it implied meant that the nation's responsibilities could not end with water supply, drainage, the prevention of the spread of infectious diseases, the adulteration of food, and the like. With the advance of knowledge, science and experience, much could be done to safeguard the personal well-being of our people beyond what we had hitherto attempted, and in devoting its mind to this purpose he believed that the medical profession had a great duty and an unexampled opportunity before it.

The Medical Service of the Air Force

A special medical service is being organized for the air force. Two main divisions of the work will be recognized, namely, (*a*) care of the effective personnel, and (*b*) care of the noneffective personnel. The former may be considered to represent the hygiene and preventive side of the work and to include such special subjects as selection and care of the flying personnel, maintenance and improvement of the physical efficiency of all ranks, sanitation, etc. The latter represents the curative side of the work, and certain subdivisions that air force experience has shown to be necessary will be recognized, namely, neurology, surgery of the eye, throat, nose and ear, and plastic surgery, etc., in addition to general medicine, surgery and pathology. Subject to the exigencies of the service, a medical officer will be selected for and eventually allocated to work in the subdivision for which his ability best suits him. Since, however, the success of any special work in the air force will depend on a sound knowledge of the conditions of life of the effective personnel, medical officers will not be earmarked for one of the special subdivisions of the medical service until selected for the higher or Grade A pay. The system of charge pay as in vogue in the navy and army medical services has been replaced in the air force medical service by a system of special merit pay. An officer once selected for Grade A pay will draw such pay for a probationary period of one year, and if then confirmed, will, except in the case of incompetence or misconduct, continue to draw this pay, however employed, until promoted to the next higher rank, when he will be placed in Grade B until again selected for Grade A.

Marriages

Asst. Surg. Henry DeWitt Hubbard, Lieutenant (Junior Grade), U. S. Navy, San Jose, Calif., on duty at the U. S. Naval Hospital, Mare Island, Calif., to Miss Cecil Wright of Huntington Park, Calif., at Pleasanton, Calif., recently.

Lieut. Edward Buckman, M. C., U. S. Army, Chicago, on duty with the Eighty-Fifth Division, Camp Custer, Mich., and now overseas, to Miss Alfreda Hartenstein of Vicksburg, Miss., at Battle Creek, Mich., recently.

Asst. Surg. George Loughlin Tully, Lieutenant, U. S. N. R. F., Boston, on duty at U. S. Naval Station, Newport, R. I., to Miss Mary Kathleen McCarthy of Newton, Mass., October 12.

Lieut. Malcolm Kinmonth Smith, M. C., U. S. Army, New York City, on duty at Fort Oglethorpe, Ga., to Mrs. Alice Boutell Ladd of Washington, D. C., recently.

Lieut. Richard Roy Turnbull Furlong, M. C., U. S. Army, New York City, to Miss Beral M. Hadley of Nova Scotia, at New York City, October 17.

George G. Reinle to Miss Evelyn A. Kane, both of Oakland, Calif., at Camp Kearney, Calif., September 25.

William D. Snively, Rock Island, Ill., to Miss Emma G. Butler of Washington, D. C., September 12.

Willis Townsend Hinman to Miss Hazel Vance, both of Moline, Ill., September 24.

Edwin Cornne Hoff, Detroit, to Miss Helen Parlette of Carey, Ohio, October 19.

Deaths

Major Alfred Reginald Allen, Infantry, U. S. Army, Philadelphia; University of Pennsylvania, Philadelphia, 1898; aged 42; a Fellow of the American Medical Association; a member and from 1909 to 1917 secretary and treasurer of the American Urological Association; twice president of the American Psycho Pathological Association, and president of the Philadelphia Urological Society; and American Association of Pathology and Bacteriology; secretary of the American delegation to the Sixteenth International Congress to Budapest, Hungary, in 1909, and to the Seventeenth International Congress in London, in 1913; lecturer in urological electrotherapeutics; associate in neurology and in neuropathology in his alma mater; who when the United States declared war against Germany entered the line rather than the medical corps, went to the Infantry School of Arms at Fort Sill, Okla., and was commissioned as major, and assigned to duty with the Three Hundred and Fourteenth Infantry; was killed in action in France during the heavy fighting northwest of Verdun, September 30.

Edwin Bradford Cragin, New York City; College of Physicians and Surgeons in the City of New York, 1886; aged 58; a Fellow of the American Medical Association, American Gynecological Society and New York Academy of Medicine; professor of obstetrics and gynecology in his alma mater; attending obstetrician and gynecologist to the Sloan Hospital for Women; consulting gynecologist to the Presbyterian, Roosevelt and Lincoln hospitals, the New York Infirmary for Women and Children and St. Luke's Hospital, Newburgh, N. Y.; author of "Essentials of Gynecology," and "A Text-Book of Obstetrics," and one of the authors of the "American Text-Book of Gynecology"; an obstetrician and gynecologist of high rank; died at his home, October, 21, from pneumonia.

Leo Smith Petersen, New York City; College of Physicians and Surgeons of the City of New York, 1911; aged 31; a member of the Medical Society of the State of New York; attending anesthetist of the German Hospital, and attending surgeon to the German Dispensary; a member of the staff of the Lenox Hill, and Skin and Cancer hospitals; national president of the Chi Zeta Chi Medical Fraternity; at one time captain in command of the First Field Ambulance, N. Y. N. G., on the Mexican border; died in the Lenox Hill Hospital, New York City, October 22, from pneumonia.

Ernest George Grey, Baltimore; Johns Hopkins University, Baltimore, 1911; aged 34; a Fellow of the American Medical Association; assistant resident surgeon at the Peter Bent Brigham Hospital, Boston, from 1912 to 1916, and at Johns Hopkins Hospital for two years thereafter; also instructor in surgery in Johns Hopkins University; recently appointed under the Rockefeller Foundation director of the surgical clinic of the Peking (China) Medical School and Hospital; died October 12, at Johns Hopkins Hospital, from pneumonia, following influenza.

Lieut. Argo Montague Foster, M. C., U. S. Army, Kaukauna, Wis.; University of Michigan, Ann Arbor, 1910; aged 33; a Fellow of the American Medical Association; local surgeon of the Chicago and Northwestern System and city health officer of Kaukauna; died, September 2, in the North Shore Hospital, Chicago, from streptococcus infection following an operation on the nose.

Act. Asst. Surg. Francis Sherman Echols, U. S. P. H. S., Washington, D. C.; Bowdoin Medical School, Brunswick and Portland, Me., 1915; aged 36; a Fellow of the American Medical Association; who had served during the early part of the war in Middlesex Hospital, London, England; died in the Walter Reed Emergency Hospital in Washington, D. C., October 15, from pneumonia, following influenza.

Lieut. Admont Halsey Clark, M. C., U. S. Army; Johns Hopkins University, Baltimore, 1915; aged 30; assistant professor of pathology in Johns Hopkins University; resident pathologist to Johns Hopkins Hospital; who had done brilliant experimental work in pneumonia and diabetes; one of the most promising of the younger pathologists of America; died in Johns Hopkins Hospital, October 13, from pneumonia, following influenza.

Charles Huff Davis, Knoxville, Tenn.; Lincoln Memorial University, Knoxville, Tenn., 1898; aged 53; a Fellow of the American Medical Association, and American Laryngological Association; vice president of the Tennessee State Medical Association, and once president of the Knox County Medical Society; a specialist on diseases of the eye, ear, nose and throat; died at his home, October 21, from pneumonia, following influenza.

Isaac K. Urich, Annville, Pa.; Jefferson Medical College, 1882; aged 55; a Fellow of the American Medical Association; for two terms representative in the state legislature from Lebanon County; secretary-treasurer of the Calcite Quarry Company, Myerstown, Pa.; for twenty years school director of Annville; died at his home, October 14, from bronchial pneumonia.

Died in the Service
IN FRANCE
MAJOR ALFRED R. ALLEN, U. S. A.
1876-1918

Capt. Fred Scates Towle, M. C., U. S. Army; on duty at Colonia, N. J.; Portsmouth, N. H.; George Washington University, Washington, D. C., 1893; aged 54; a Fellow of the American Medical Association, and president of the New Hampshire Medical Society in 1917-1918; surgeon-general of New Hampshire from 1897 to 1899; city physician of Portsmouth, and chairman of the local board of health; assigned to duty with Base Hospital No. 3, Colonia, N. J.; lost his life in a fire which destroyed the officers quarters at that post, October 9.

Robert Coleman Kemp, New York City; College of Physicians and Surgeons in the City of New York, 1889; aged 53; a Fellow of the American Medical Association; professor of gastro-intestinal diseases in Fordham University, New York City; visiting gastro-enterologist to Fordham University Clinic, and consultant in gastro-intestinal diseases to the Manhattan State Hospital; died at his home, October 23, from pneumonia, following influenza.

Capt. Victor Moreau Rice, M. C., U. S. Army, Batavia, N. Y.; University of Buffalo, N. Y., 1904; aged 38; a Fellow of the American Medical Association, and a specialist on roentgenology; on duty with Company 21, M. O. T. C., Camp Greenleaf, Fort Oglethorpe; died in General Hospital No. 14, Fort Oglethorpe, October 13, from pneumonia, following influenza.

Lieut. Earle Robinson Ackley, M. C., U. S. Army, Bartow, Fla.; Medical College of Ohio, Cincinnati, 1904; aged 44; a Fellow of the American Medical Association, and of the Cincinnati Academy of Medicine; on duty at Camp Greenleaf, Fort Oglethorpe, Ga.; died in the General Hospital, Fort Oglethorpe, October 13, from pneumonia, following influenza.

Lieut. Max Marowitz, M. C., U. S. William H. H. Smith, Council Grove, Kan.; Northwestern Medical College, St. Joseph, Mo., 1892; aged 60; at one time a Fellow of the American Medical Association; died at his home, September 28, from cerebral hemorrhage.

John Richard Perkins, New York City; College of Physicians and Surgeons in the City of New York, 1918; aged 26; an intern in the Presbyterian Hospital, New York City; died in that institution, October 9, from pneumonia.

Thomas Nash Broaddus, Richmond, Va.; Medical College of Virginia, Richmond, 1911; aged 31; a Fellow of the American Medical Association; died at his home, October 5, from bronchopneumonia, following influenza.

Asst. Surg. Harry Ellsworth Davey, Lieut. (j. g.) U. S. N. R. F., Keene, N. H.; Boston University, 1913; aged 34; a Fellow of the American Medical Association; died at his home in Keene, October 15, from influenza.

Wolf Samuel Schrayer, Chicago; University of Warsaw, Russia, 1895; Harvey Medical College, Chicago, 1900; aged 49; a Fellow of the American Medical Association; died at his home, October 14, from pneumonia.

Mathis Daniel Linehan, Dubuque, Iowa; St. Louis College of Physicians and Surgeons, 1906; aged 35; a member of the Iowa State Medical Society; died at his home, October 15, from pneumonia, following influenza.

Clifton Norwood De Vilbiss, Laytonsville, Md.; University of Maryland, Baltimore, 1910; aged 33; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, October 15, from pneumonia.

Walter S. Lincoln, Dodgeville, Wis.; University of Illinois, Chicago, 1897; aged 54; a Fellow of the American Medical Association; health officer of Dodgeville; died at his home, about October 14, from pneumonia.

Harry Mayer Schall, Rochester, N. Y.; Jefferson Medical College, 1887; aged 55; a member of the Medical Society of the State of New York; died in the Rochester General Hospital, October 9, from heart disease.

Laura Bell Stoner, Battle Creek, Mich.; American Medical Missionary College, Chicago, 1904; aged 39; a member of the staff of the Battle Creek Sanitarium; died in Atlanta, Ga., October 23, from pneumonia.

John Aimone, Granville, Ill.; University of Illinois, Chicago, 1907; aged 37; a Fellow of the American Medical Association; died at his home, October 4, from bronchial pneumonia, following influenza.

John Frank Marshall, Ashland, Pa.; University of Pennsylvania, Philadelphia, 1907; aged 36; a Fellow of the American Medical Association; died at his home, October 9, from pneumonia, following influenza.

Albert Harry Herr, Okmulgee, Okla.; Chicago College of Medicine and Surgery, 1912; aged 30; a Fellow of the American Medical Association; died at his home, October 8, from pneumonia, following influenza.

Harvey F. Eichman, Chicago; Chicago College of Medicine and Surgery, 1910; aged 40; a Fellow of the American Medical Association; died at his home, October 14, from pneumonia, following influenza.

William H. Wells, Stronghurst, Ill.; University of Illinois, Chicago, 1897; aged 57; a Fellow of the American Medical Association; died in the Galesburg Hospital, October 5, from pneumonia, following influenza.

Nellie S. Hayes, Los Angeles; University of Southern California, Los Angeles, 1904; aged 42; a Fellow of the American Medical Association; died at her home, October 11, from pneumonia, following influenza.

Sigurd Peter Dahl, Decorah, Iowa; Drake University, Des Moines, Iowa, 1913; aged 33; a Fellow of the American Medical Association; died at his home, October 9, from pneumonia, following influenza.

Henry W. Dew, Lynchburg, Va.; College of Physicians and Surgeons, Baltimore, 1886; aged 56; a Fellow of the American Medical Association; died at his home, October 17, from pneumonia, following influenza.

Isadore Jacques Grossman, Brooklyn; University and Bellevue Hospital Medical College, 1915; aged 26; house physician of the Jewish Hospital, Brooklyn; died at his home, October 13, from pneumonia.

James Elmer Chapman, Bloomingburg, Ohio; Starling Medical College, Columbus, Ohio, 1903; aged 46; a member of the Ohio State Medical Association; died at his home, October 5, from influenza.

Carl Neal Etchison, Gaithersburg, Md.; Maryland Medical College, Baltimore, 1908; aged 32; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, October 17, from influenza.

William Garner White, York, S. C.; University of Maryland, Baltimore, 1883; aged 60; at one time a member of the South Carolina Medical Association; died at his home, October 12, from pneumonia.

Joseph Johnston Stevens, Hattiesburg, Miss.; Tulane University, New Orleans, 1890; aged 51; at one time a Fellow of the American Medical Association; died at his home, October 15, from heart disease.

Ernest William Auzal, New York City; University of Vermont, Burlington, 1884; aged 58; a Fellow of the American Medical Association; a specialist in neuropathology; died at his home, October 11.

Henry M. Fagaines, Chandler, Okla.; University of Wooster, Cleveland, 1880; aged 61; formerly a member of the Oklahoma State Medical Association; died at his home, October 12, from pneumonia.

Elizabeth Aileen Lynch Schuler, Winona, Minn.; Milwaukee Medical College, 1910; aged 34; a member of the Minnesota State Medical Association; died at her home, October 18, from influenza.

J. P. Phillips, Florala, Ala.; Memphis Hospital Medical College, 1898; at one time a member of the Medical Association of the State of Alabama; died at his home, October 11, from influenza.

John G. Hoeckh, Buffalo; University of Buffalo, 1907; aged 33; clinical pathologist to the Ernest Wende Hospital, and assistant physician of Erie County; died at his home, October 5, from pneumonia.

Munroe Dart Youngman, Ardmore, Pa.; Hahnemann Medical College, Philadelphia, 1911; aged 32; a Fellow of the American Medical Association; died at his home, October 11, from pneumonia.

Lou N. Byers, Aurora, Ill.; Chicago College of Medicine and Surgery, 1911; aged 33; a Fellow of the American Medical Association; died at her home in Aurora, October 3, from pneumonia.

Lieut. Clark Denike Fanton, M. C., U. S. Army, Riverside, Calif.; State University of Iowa, Iowa City, 1915; aged 30; is reported to have died, recently, at a military camp in California.

David Robert Hancock, Redondo Beach, Calif.; Starling Medical College, Columbus, Ohio, 1892; aged 48; city health officer since 1894; died in Redondo Beach, October 14, from pneumonia.

Robert M. C. Gavin, Tonganoxie, Kan.; Philadelphia University of Medicine and Surgery, 1878; aged 61; for many years a practitioner of Lebo, Kan.; died at his home, October 5.

Edward J. Murray, Scranton, Pa.; Baltimore Medical College, 1910; aged 33; at one time a Fellow of the American Medical Association; died at his home in Throop, Pa., about October 9.

Fred McVey Towles, Fort Wayne, Ind.; Medical College of Indiana, Indianapolis, 1902; aged 45; assistant surgeon of the Pennsylvania System, at Fort Wayne; died at his home, October 8.

Leo Gernand Maury, Chicago; Northwestern University Medical School, Chicago, 1918; aged 23; an intern in Michael Reese Hospital; died in that institution, October 19, from influenza.

John Henry Bender, Wetzel, Ohio; Ohio State University, Columbus, 1912; aged 31; a member of the Ohio State Medical Association; died at his home, about October 9, from influenza.

William Francis Brown, Roxbury, Boston and Nahant, Mass. (license, Massachusetts, years of practice); aged 61; died at his summer home in Nahant, October 2, from heart disease.

Warren B. Rush, Lake City, Fla.; Jefferson Medical College, 1893; aged 70; a Fellow of the American Medical Association; died at his home, September 11, from cerebral hemorrhage.

Jacob Chasan, New York City; Long Island College Hospital, Brooklyn, 1911; aged 34; assistant physician to the Bronx Hospital; died at his home, October 9, from pneumonia.

Jesse D. Hodges, Little Rock, Ark.; Chicago College of Medicine and Surgery, 1914; aged 35; president of the Arkansas Pharmaceutical Association; died at his home, October 15.

Herbert Sumner Reynolds, Clinton, Conn.; New York University, New York City, 1881; aged 58; died in Grace Hospital, New Haven, Conn., October 9, after a surgical operation.

Ancil Gatliff, Williamsburg, Ky.; Hospital College of Medicine, Louisville, Ky., 1876; aged 70; one of the largest coal operators of eastern Kentucky; died at his home, October 14.

Frank Horan Collins, New York City; University of Pennsylvania, Philadelphia, 1906; assistant surgeon to the Throat, Nose and Lung Hospital; died at his home, about October 14.

Charles H. Hunter, Minneapolis, College of Physicians and Surgeons in the City of New York, 1878; aged 65; died at the Eitel Hospital, Minneapolis, October 15, from nephritis.

Abraham James Gordon, Philadelphia; Jefferson Medical College, 1912; aged 29; intern in the Jewish Hospital, Philadelphia; died in that institution, October 6, from influenza.

Lieut. Carl Stoepler, M. C., U. S. Army, Philadelphia; Medico-Chirurgical College of Philadelphia, 1912; aged 36; died in the Polyclinic Hospital of Philadelphia, October 9.

Capt. William Fielding McIsaac, C. A. M. C., Antigonish, Nova Scotia; on duty with No. 9 Stationary Hospital in France, is reported to have died from wounds, recently.

William Harris Corson, Jr., Collegeville, Pa.; Hahnemann Medical College, Philadelphia, 1909; aged 34; died at his home, October 9, from pneumonia, following influenza.

James F. Folz, Philadelphia; Medico-Chirurgical College, Philadelphia, 1897; aged 45; district city physician; died at the Northeast Hospital, October 10, from pneumonia.

Bernard William Junge, New York City; University of Buffalo, N. Y., 1900; aged 49; a Fellow of the American Medical Association; died at his home, October 12.

Walter Arthur Watts, Pawtucket, R. I.; University of Vermont, Burlington, 1910; aged 38; city physician of Pawtucket; died at his home, October 7, from influenza.

George Lewis Smith, Philadelphia; University of Pennsylvania, Philadelphia, 1897; aged 47; died at his home, October 10, from pneumonia, following influenza.

John Francis Munns, Bremerton, Wash.; University of Minnesota, Minneapolis, 1903; aged 46; died at his home, October 13, from pneumonia, following influenza.

Benjamin J. See, Harris, Ill. (license, years of practice, Illinois, 1878); aged 94; a practitioner for sixty-five years; died at the home of his son in Paris, October 11.

Chauncey Benjamin Lambert, Riverside, N. J.; Hahnemann Medical College, Philadelphia, 1904; died at his home, October 8, from pneumonia, following influenza.

Edward Stack Grace, New Britain, Conn.; University of Vermont, Burlington, 1914; aged 29; died at his home, October 8, from pneumonia, following influenza.

Frank Timothy Mara, Boston; Harvard Medical School, 1887; aged 52; died in St. Elizabeth's Hospital, October 3, from pneumonia, following influenza.

Charles Emera James, Laurel, Del.; Jefferson Medical College, 1911; aged 33; formerly of Charptown, Md.; died at his home, October 13, from influenza.

Capt. J. T. Whitworth Boyd, C. A. M. C., Port Arthur, Ont.; Queens University, Kingston, Ont., 1914; is reported to have died from wounds, recently.

Francis M. Yost, Center Point, Iowa (license, Iowa, years of practice, 1887); aged 87; a practitioner of medicine since 1853; died at his home, October 12.

Grant Mitchell, Pittsburgh; University of Illinois, Chicago, 1896; aged 54; a practitioner of dentistry for thirty-two years; died at his home, October 1.

Work A. Streeter, Harrisburg, Pa.; Hahnemann Medical College, Philadelphia, 1916; aged 28; died in Harrisburg, October 14, from pneumonia.

Edward Joseph Therrien, Marlboro, Mass.; Ecole de Médecine et de Chirurgie, Montreal, 1886; aged 62; died at his home, about October 13.

Capt. M. A. McKechnie, C. A. M. C., Walkerton, Ont.; Queens University, Kingston, Ont., 1917; is reported to have died of wounds, recently.

George Whitefield Holmes, Atlanta, Ga.; Atlanta Medical College, 1898; aged 64; died at a private sanitarium, in Atlanta, October 14.

Samuel C. Blair, Philadelphia, University of Pennsylvania, Philadelphia, 1878; aged 64; died at his home, October 9, from heart disease.

Abram B. Patton, Waynesburg, Pa.; Jefferson Medical College, 1877; aged 67; died at his home, October 9, from cerebral hemorrhage.

Robert J. Cunniff, Philadelphia; Maryland Medical College, Baltimore, 1909; aged 37; died at his home, October 7, from pneumonia.

Earl Clifton West, Laurel, Del.; Maryland Medical College, Baltimore, 1912; aged 33; died at his home, October 13, from influenza.

James Mackay Montgomery, Philadelphia; Jefferson Medical College, 1897; aged 55; died at his home, October 7, from influenza.

Robert A. Baldridge, Farmersburg, Ind.; Eclectic Medical Institute, Cincinnati, 1884; aged 82; died at his home, October 3.

Albion Horace Allen, New London, Conn.; Boston University, 1875; aged 81; died at his home, about September 17.

Stephen John Songy, Wallace, La.; Tulane University, New Orleans, 1913; aged 29; died at his home, recently.

Correspondence

THE TREATMENT OF "SPANISH INFLUENZA"

To the Editor:—In a number of cases of influenza and influenzal pneumonia, seen both in my private practice and at the Alexian Brothers' Hospital, I have used a treatment from which my results have been most satisfactory.

The clinical course of the condition may be divided for convenience into three stages. The first lasts from three to four days, and is characterized by chills, fever, muscular pain, etc. The second is of rather uncertain duration, and is characterized by involvement of the respiratory system varying in degree from a slight catarrhal condition to the involvement of a large area of one or both lungs. The third is characterized by disturbances of the circulatory system, dyspnea and cyanosis.

In the treatment, the patient receives as soon as possible from 10 to 20 c.c. of a saturated solution of quinin hydrochlorid. This is given intravenously and is repeated once or twice in twenty-four hours. It is followed for from two to five days by one or two daily injections of the same solution, the quantity depending on the condition of the patient. In addition, the patient receives 4 grains of quinin bisulphate and 6 grains of sodium salicylate over three hours. This may be given either in capsules or solution, but it is important that the two drugs be given together. I make it a rule to continue the intravenous injection until the temperature remains normal or subnormal for at least thirty-six hours; I continue the quinin and the sodium salicylate until the temperature has continued normal or subnormal for three consecutive days. With this treatment, all patients that came under my observation within three days of the onset of symptoms made a rapid and uninterrupted recovery within from one to three days. In no case did they continue into the second stage, or show any complication. Patients that came under my observation in whom the symptoms lasted more than three days, and those of the second stage with respiratory symptoms, all made rapid and uninterrupted recovery in from one to eight days. We also had a very slight mortality in cases of the third stage.

Under this treatment a marked improvement may be noticed in the leukocyte count. In cases in which the leukocyte count was 2,000 before the injection there was a decided rise to 4,000 or 5,000 immediately following the first injection, and after repeated injections even as high as 21,000.

I cannot too strongly call attention to the importance of keeping the bowels open by mild cathartics. Often a lingering temperature disappeared after a brisk flushing of the bowels, and this method greatly aided in shortening the course of the disease.

Some may regard the dosage of quinin given as heroic, but I find that it represents rather the minimum than the maximum amount with which results may be obtained.

H. A. Klein, M.D., Chicago.

DEPENDABILITY OF DOSAGE IN TABLETS

To the Editor:—In your article—"Dependability of Dosage in Tablets" (The Journal A. M. A., *July 27, 1918*), we feel that an unintentional injustice has been done us. In citing the work done by the Connecticut Agricultural Experiment Station, and stating that "Allowing a tolerance in composition of 10 per cent., one or more products of the following manufacturers were found deficient," our name has been included in this list. In your brief abstract of the matter it was not possible to state that of the twelve samples of tablets of our manufacture (The G. F. Harvey Company and the Harvey Company are one and the same) examined in 1916 and 1917, that while one sample was found deficient in strength, this sample was of such a nature that it could not by eminent authorities be expected to test up to labeled strength.

The sample here referred to is Digestive Aromatic Tablets. Leading authorities on combinations of Pepsin and Pancreatin, including the very chemists who made the examinations in question, including also the authorities quoted in your article in the A. M. A., Aug. 20, 1910, on Aromatic Digestive Tablets, concede that there is an interaction when in combination, in tablets made by the generally approved methods.

The general method in making compressed tablets is that after mixing carefully the several ingredients, the mixture is moistened sufficiently to permit of a granulation being made and such granulation is then dried carefully with regulated artificial heat. While it would be possible in this particular tablet to make separate granulations of the incompatible substances and mix such granulations only after each is thoroughly dry, yet the tablets would not be more valuable because the destructive process would ensue after the tablets came in contact with the secretions of the alimentary tract.

In view of these facts, we think we should be exonerated from any adverse criticism on this twelfth sample of ours examined and we thank you most heartily for your spirit of fairness in now calling this matter to the attention of the readers of The Journal.

The Harvey Co., Saratoga Springs, N. Y.

[Comment.—The Harvey Company seems to hold the opinion that it does not matter whether or not Aromatic Digestive Tablets contain the amount of ferments claimed on the label, since, in any case, these ferments would mutually destroy each other, as soon as such tablets came in contact with the digestive secretions. No excuse can be, or is, offered for those physicians who prescribe such absurdities as Aromatic Digestive Tablets (The Journal, Aug. 20, 1910, p. 710), but neither is there any justification for a firm selling a product which it knows will not measure up to the claims made for it. In this connection, it is worth repeating what The Journal said on this subject as long ago as *Dec. 19, 1914*:

> "Manufacturers are warned by the Department of Agriculture through the Bureau of Chemistry, that combinations claiming to contain digestive enzymes must be active when sold. If preparations tend to deteriorate in a short time, each lot should be dated and not sold after the period when they become inactive. While every manufacturer must be considered innocent until proved guilty and ignorant until proved knowing, it is a matter of knowledge that many manufacturers have marketed their various digestive mixtures with full appreciation of their worthlessness.—Ed.]

POINT OF VIEW OF JOHN AMES MITCHELL, PUBLISHER OF LIFE

To the Editor:—I have been greatly interested in a biographic sketch of John Ames Mitchell, proprietor of *Life*, published in the *Harvard Graduates' Magazine*, September, 1918. The biography was written by E. S. Martin of the class of '77 of Harvard University. We all have enjoyed Mr. Mitchell's attacks on the medical profession, which rarely failed to be found in every number of *Life*. The part of the biography which interests the readers of The Journal is as follows:

> He was by no means completely educated. But no one ever is. He was cultivated, his taste was trained, and whether it dealt with art, letters or deportment, it was good taste. But imperfect knowledge of facts, or unwillingness or inability to weigh them, often led him to queer conclusions which he stuck to with the utmost tenacity. About medicine, for example, he was not only a heretic, but a fighting opponent of pretty much the whole scheme of modern medicine. Not only he hated and fought vivisection, against which there is plenty to be said, but all the use of serums was abhorrent to him. He would deny that vaccination had abated smallpox, and say that sanitation had done it. If he could, he would have forbidden inoculation for typhoid.
>
> Modern medicine is not perfect, and assaults on it are not without value. When bleeding was the accepted practice, Molière was scandalous when he ridiculed it. It is quite conceivable that modern medical practice will give way as knowledge advances to something better, but while it lasts it is held to be almost treasonable to doubt it, and whoever attacks it has need of courage.
>
> Mitchell had the courage. He always had the courage to attack anything he thought was wrong, and whether or not it grieved the readers of *Life* or advertisers it never gave him much concern.

All that is good in medicine has never suffered from the wit and sarcasm which Mitchell was constantly hurling at the profession. His biographer has clearly indicated that there was no malice in these missiles. We are all aware of the shortcomings of medicine. The profession will never suffer from attacks, even to a certain extent baseless, which are made either in a spirit of amusement or from a genuine desire to criticize. I, for one, shall miss Mitchell's arrows, and *Life* will be less interesting by reason of his death. I once had in mind to write to Mr. Mitchell that inasmuch as he was continually attacking the medical profession, whose purpose it is to save life, he ought to change the title of his paper to *Death*. He perhaps would not have acted favorably on my suggestion.

H. W. Wiley, M.D., Washington, D. C.

"THE PROPAGANDA OF THE V. M. S. C."

To the Editor:—An editorial comment in The Journal (Oct. 5, 1918, p. 1141) contains a reference to a proposed resolution in the *Bulletin* of the Buchanan County Medical Society bearing on the membership therein as related to the Volunteer Medical Service Corps. The *Bulletin* was in error in stating that the resolution was introduced at the request of the Council of National Defense, Medical Section. It was introduced at the request of the Missouri State Committee of the Council of National Defense, Medical Section.

Daniel Morton, M.D., St. Joseph, Mo.
President, Buchanan County Medical Society.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DELAY IN RECEIPT OF ORDERS

To the Editor:—Please advise me as to the correctness of the information in The Journal, October 12, concerning Dr. M. W. R. of Missouri. The item stated that Lieut. M. W. R., Missouri, had orders, or was to proceed to Fort Riley, Kan., for a course of instruction. Did I read it right? So far I have not received any orders to report, and am anxious to get them.

M. W. R., M.D., Missouri.

Answer.—This question is continually coming in. The orders as published in The Journal are taken from the carbon copies of the orders sent by the Surgeon-General's Office to the Adjutant-General's Office. Frequently considerable delay occurs in the Adjutant-General's Office. If the order appears in The Journal but is not received by the officer within a reasonable time, he should write to the Surgeon-General's Office, stating the facts.

DIPHTHERIA ANTITOXIN TREATMENT OF INFLUENZA

To the Editor:—Please advise me as to the value of diphtheria antitoxin in the treatment of the present epidemic of influenza.

Alward H. White, M.D., Shafter, Texas.

Answer.—There is no scientific reason to believe that diphtheria antitoxin can have any more value in influenza than an equal quantity of horse serum.

BEST WAY TO KEEP STATIC MACHINES DRY

To the Editor:—In The Journal, Aug. 31, 1918, M. H. F. makes inquiry as to the best and cheapest method of keeping the air within a static machine dry. If the doctor will keep a dish containing about 1 pound of sulphuric acid (92.5 per cent.) in one end of the machine, he will find that moisture will give him no trouble. The acid must be changed about once in three or four months, as it absorbs so much water in that length of time that it becomes ineffective.

M. G. Sloan, M.D., Des Moines, Iowa.

Epinephrin in Treatment of Eczema.—The *Riforma Medica* quotes the *Annali di Medicina Navale* of July 22, 1918, to the effect that P. Trapani found that many forms of eczema subsided under subcutaneous injection of epinephrin. He injected it in the buttocks or in the vicinity of the focus, commencing with ⅛ mg. in physiologic solution and increasing to ¼ mg. He never had to make more than fifteen or twenty injections at most, giving them daily or on alternate days. Even chronic eczema of long standing subsided the same as the acute and partial.

Virginia June Examination

Dr. J. W. Preston, secretary of the Virginia State Board of Medical Examiners, reports the written examination held at Richmond, June 18-21, 1918. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of 42 candidates examined, 37, including 1 osteopath, passed, and 5 failed. Thirteen candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Howard University	(1917)	86
Bennett Medical College	(1909)	82

Book Notices

Practical Guide to Diseases of the Throat, Nose, and Ear. For Senior Students and Junior Practitioners. By William Lamb, M.D., C.M., M.R.C.P. Fourth Edition. Cloth. Price, $3.00. New York: William Wood & Co., 1918.

This little volume, intended primarily for the student and general practitioner, is fairly comprehensive, though devoid of much important detail. The subject matter is considered mainly from the standpoint of symptomatology and treatment. The various affections of the throat, nose and ear are not treated as entities but grouped under a few headings. For instance, all symptoms arising from nasal affections are discussed in one or two chapters, and the diagnosis of the different diseases responsible for them indicated according to the predominance of one or more symptoms or group of such findings, following which the treatment is taken up as directed toward this, that or the other combination. The author is conservative in his surgical treatment of tonsillar affections, giving more prominence to tonsillotomy and reserving complete enucleation only for certain well defined cases. This is rather contrary to the generally accepted American view on this subject. Criticism of this attitude, however, should be cautious, as the last word on the tonsil question has yet to be spoken; we are not in the position to say whether the author's views are antiquated or a step ahead of us. Especially meritorious are the chapters on the danger symptoms in suppurative ear diseases and the indications for surgical intervention. These are of high importance to the general practitioner and seldom have been so clearly set forth as in this book. Sufficient of the complex anatomy of the throat, nose and ear is given to make the text more intelligible and to refresh the memory of the general practitioner, to whom these structures have always been more or less of a muddle.

Neurological Clinics: Exercises in the Diagnosis of Diseases of the Nervous System. Given at the Neurological Institute, New York, by the Staff of the First Division. Edited by Joseph Collins, M.D. Cloth. Price, $3. Pp. 271. New York: Paul B. Hoeber, 1918.

The subtitle, "Exercises in the Diagnosis of Diseases of the Nervous System," indicates the function of this volume; it consists of a collection of forty-one reports made by the staff of the first division of the New York Neurological Institute. With few exceptions each of the reports is of a single case, and in length they vary from two to twenty-eight pages. Most of the cases are organic, but there is an excellent report (by Naccarati) on obsessions and fixed ideas; one on a case of paramyoclonus multiplex, and three on dementia praecox. The organic cases present a wide diversity, and every one is interesting and instructive. Vascular lesions, syphilis and tumors receive considerable attention, while of the more unusual things may be instanced progressive hemiplegia, astereognosis without hemiplegia, partial blindness from disease of the accessory nasal sinuses, symptomatic tic douloureux, disseminated lesions of the spinal cord due to malaria, and sudden paraplegia after injections of autolysin (Beebe's serum). Neither neurologist nor general practitioner can read this book without edification and benefit; it is a good place to look for help on a puzzling case.

Clinical Diagnosis: A Manual of Laboratory Methods. By James Campbell Todd, Ph.B., M.D., Professor of Clinical Pathology, University of Colorado. Fourth edition. Cloth. Price, $3 net. Pp. 687, with 244 illustrations. Philadelphia: W. B. Saunders Company, 1918.

The author has had as his aim in the preparation of this manual a practical work for the student and the practitioner rather than the laboratory worker. Clearness and simplicity are requisites for such a book; clearness in description of tests and processes, simplicity in apparatus and equipment—not too many methods, but judicious selection of those to be emphasized and recommended. This has been attained satisfactorily. The considerable amount of space devoted to the technic of the microscope is worth while, the illustrations, both colored plates and photomicrographs, are good, and the information given is up to date, while the interpretation of findings is of great practical value. In this edition many subjects are elaborated, others added, some omitted, and the whole work thoroughly revised.

Medicolegal

Insufficient Evidence of Malpractice—Results and Requirements

(O'Grady v. Cadwallader (Iowa), 166 N. W. R. 755)

The Supreme Court of Iowa, in affirming a judgment in favor of the defendant, who was charged with negligence in reducing and treating a fracture of the radius of the plaintiff's left arm, says that this was purely a fact case, with the burden of proof resting on the plaintiff. The allegation of negligence on which recovery was sought was, first, that the defendant was negligent in not reducing the fracture properly, and second, that he was negligent in using only pasteboard splints at first, and afterward inadequate and improper splints, and in not applying proper bandages and appliances to keep the broken ends in alinement or proper apposition. But there was no direct evidence that the fracture was not properly reduced; no direct evidence that the splints and bandages were not the splints and bandages that are usually and ordinarily used by physicians in the treatment of such injuries; no direct evidence that they were not properly placed on the arm by the defendant at the time.

There was only the following showing as a basic fact on which to conclude, deductively, that the fracture was not properly reduced, and that the proper appliances were not made to hold it in position after reduction: Some of the physicians called by the plaintiff testified that from an examination of roentgenograms made a little more than three months and a half after the fracture, when the plaintiff went to another physician, the bone did not there appear to have been placed in proper apposition, that the alinement was not perfect, and that this condition might be due to the manner in which the fracture was reduced in the first place, or to the manner in which it was treated after it was reduced. But it also appeared from the other physician to whom the plaintiff went that these pictures did not show the true condition of the bone, its position and alinement, as it was actually found by him when he made an incision baring the bone, and did not show the true relationship of the radius to the ulna and the true condition of the fracture. His testimony led the mind to the conclusion that the only defect or deformity found was due to excessive callus adhering to the ulna; that this, chiseled away, left the arm with all its functions perfectly normal. Nor was there anything in the record to show that when the plaintiff ceased his treatments at the hands of the defendant the period had passed when the physician, in good judgment, should have resorted to the open method for relief.

On the facts shown in this record, the court feels that any verdict rendered by a jury would rest on the merest speculation, and could find no support in any tangible fact shown by the plaintiff. A verdict for the plaintiff could not stand on this record, and the trial court was justified in directing a verdict for the defendant.

There is no implied guaranty of results, and all the law demands is that the practitioner bring to the service of his patient and apply to the case that degree of skill and care, knowledge and attention ordinarily possessed and exercised by practitioners of the medical profession under like circumstances and in like localities, and it is the general holding of the courts that the bare fact that full recovery does not result, or that a surgical operation is not entirely successful, is not, in and of itself, evidence of negligence; and, in the absence of any showing from those learned in the profession that there was a failure to do that which ought to have been done in the treatment of the injury, or that there was that done which ought not to have been done in the treatment, there can be no recovery of damages. The fact on which negligence is predicated must be shown either affirmatively, by direct evidence, or deductively, by conditions shown to exist after the treatment. But conditions, even though they show bad results, are not in and of themselves sufficient, but such results may form a basis on which an expert, learned in the profession, may be permitted to base an opinion that the operator failed in the full discharge of his duty in the treatment of the case, or the results would not appear as they are.

10. **Hemangioma of Liver, Skull and Suprarenals.**—A brief summary of the pathologic findings in this case showed: 1. A huge hemangioma of the liver weighing nearly one half (4.9) of the entire weight of the patient. This hemangioma was a growing tumor, an example of a true hemangioblastoma. 2. Two hemangiomas of the skull, located in the temporal bones. 3. Multiple cysts of both suprarenals, apparently the result of congenital disturbances of growth in which connective tissue lymphatics and blood vessels have all played a rôle. Degenerative changes were very marked.

11. **Tumor Involving Gasserian Ganglion.**—In Frazier's patient the operation was performed within three months of the first symptom. The patient was seen fifteen months after the operation and, apart from certain paresthesias, which might well have been due to avulsion of the sensory root, there were no signs of recurrence. The tumor was an endothelioma.

14. **Multiple Neurofibromatosis.**—A description is given by Preiser and Davenport of the occurrence of von Recklinghausen's disease in a father and son, with the necropsy findings in the case of the father, in whom the disease lasted thirteen years. In the case of the son the disease associated with definite mental inferiority and delayed sexual development. A review and analysis of the literature of 243 cases of multiple neurofibromatosis is made, as well as an analysis of thirty cases of the familial type, with charts of families in which there were two or more affected persons in one family. This establishes its hereditary tendency, showing the hereditary factor to be dominant, there being something in the germ plasm that positively facilitates the production, under appropriate stimulation, of tumors of the nerve sheaths. The relation of neurofibromatosis to malignancy is discussed.

16. **Cervical Sympathetic Ganglia and Exophthalmic Goiter.**—Experiments made by Wilson to determine the effect directly on the cervical sympathetic ganglia and indirectly on the thyroid of various forms of stimulation applied to the ganglia of goats showed that irritation from the presence of certain bacteria within the cervical sympathetic ganglia may produce histologic pictures within the ganglia and in the thyroid which parallel those found in the various stages of progressive and regressive exophthalmic goiter. In Wilson's opinion this evidence supports the suggestion that in exophthalmic goiter the thyroid receives its stimulus to overfunction through its nerve supply and as a result usually of a local infection in the cervical sympathetic ganglia.

17. **Ectopic Contractions and Ventricular Preponderance.**—The electrocardiograms of 375 patients who presented some cardiac disturbance (a few were taken on patients in whom no cardiac lesion was suspected), were reviewed by Strauss. Thirty-six per cent. showed evidence of left ventricular preponderance and 10 per cent. showed evidence of right ventricular preponderance, while 2 per cent. showed an apparent change in preponderance at different times and under varying conditions. Premature contractions of all types occurred seventy-six times. In the sixty-three individual cases showing premature beats, eleven showed at least two different types while two cases showed origin in three different foci. Left ventricular premature beats were most frequent, right ventricular, auricular and junctional contractions occurring next in order in diminishing frequency. The greatest percentage of right ventricular preponderance showed right ventricular premature contractions, while the largest percentage of left ventricular preponderance showed ectopic beats arising in the left ventricle. From these facts Strauss deduces a possible etiologic theory to account for the relationship of preponderance and the origin of ectopic beats.

19. **Streptococcus Hemolyticus Reinfection.** — Clendening gives the incidence of *Streptococcus hemolyticus* reinfection in lobar pneumonia, measles and scarlet fever as it occurred at the base hospital, Fort Sam Houston: From Dec. 1, 1917, to March 1, 1918, there were admitted 319 cases of primary lobar pneumonia; forty-four became reinfected with *Streptococcus hemolyticus.* There were ninety-seven cases of empyema with thirty-two deaths. Eighteen of the deaths were due to the streptococcus. There were six cases of delayed resolution with four deaths; one case of lung abscess with profuse expectoration of evil smelling mucilaginous sputum which contained both pneumococci, streptococci and hemolytic streptococci. The patient recovered. Four patients had localized areas of persistent pulmonary infection but finally recovered. During this same period there were admitted to the hospital 716 cases of measles. Many of the cases of otitis media cultured had streptococci present. So also did certain of the tonsillitides, etc. In all there were about 150 cases of otitis; eighty-nine cases of bronchopneumonia (forty-two deaths); twelve cases of articular rheumatism, nonsuppurative, one case of suppurative arthritis, with general sepsis, and two cases of meningitis with general sepsis. All of these may be ascribed to *Streptococcus hemolyticus.* The complications known to be due to *Streptococcus hemolyticus* in measles were ninety-seven. In 134 cases of scarlet fever there were seven cases of streptococcus reinfection. Three of these were pneumonias, with one death.

The procedure now instituted at this hospital is to segregate every case of pneumonia, every case of measles and every case of scarlet fever for a twenty-four hour period. During this time a swab culture is made of the throat. When it has been determined by the laboratory whether or not the patient is a streptococcus carrier he is delivered to a proper ward. Prior to the determination of the presence of the streptococcus in the patient's throat he should have individual isolation—if possible in a room or a tent by himself; if not, then in a room with as few other patients as possible, separated from them so far as possible, and with the most rigid prevention of contact, by use of screens or sheets between beds. With an adequate number of single rooms in a receiving ward this could be accomplished there, it being the duty of the receiving officer to see that all cases are properly cultured and reported to the proper ward. In addition to this it may be necessary to culture the nonstreptococcus wards at various intervals, probably once or twice a week, as there will be some streptococcus carriers not detected on a single throat swab. Separation of beds by sheets is of course still necessary. The incidence of bronchopneumonia in measles by this method is considerably cut down. The result of separating streptococcus carriers with lobar pneumonia has entirely done away with streptococcus reinfections.

58. **Experimental Parotitis.**—A new series of inoculat into cats of the *filtered sterile salivary secretions* der from cases of parotitis was made by Wollstein. They firm the observations made in 1915-1916 and confirm evidence of the filterable nature of the causative age mumps has been obtained. It has been determined tha saliva of man and of inoculated cats, and the inoc glands of the latter animals, contain the filterable, inf agent. The "virus" of parotitis was detected most r in the saliva during the first three days of the diseas easily on the sixth day, and not at all on the ninth d was detected also in the blood of patients showing constitutional symptoms, and in the saliva of a case of rent mumps at the periods of enlargement of the glands, but not two weeks after the swelling had s It was not detected in the cerebrospinal fluid.

60. **Nonpathogenic Tetragenous Ameba.**—In the s the amebas of dysentery Shimura discovered in the healthy persons a new type of tetragenous ameba like the dysentery ameba, forms a cyst contain daughter nuclei, but which differs from it in biol morphologic properties. Experiments made on ani clinical findings have demonstrated the nonpathog the new organism.

This ameba was observed by the author in six c is, in five persons with a normal condition of tl and in one having a chronic catarrh of the lar not dysenteric in character. In every instance t form of the ameba was found in the saline (diarrheal stools and the cyst *in the form* person failed to show any symptoms of a even after long purging; on discontinui evacuated normal dejecta and showed n illness.

61. **Rat and Poliomyelitis.**—The ce and other viscera of six rats, collecte bauer in a district in Greater New Y of epidemic poliomyelitis occurred, able of inciting, on inoculation, exp *Macacus rhesus* monkeys. The vi into the brain of white rats doe as four days in a form or in infection when inoculated intrac lure of the virus injec

)es not appear probable, therefore, that the rat acts in re as the reservoir of the virus of poliomyelitis.

. **Antimeningitis Vaccination.**—Following an outbreak of emic meningitis at Camp Funston, Kansas, in October and ember, 1917, a meningococcus vaccine suspended in salt ion was given subcutaneously as a prophylactic to about volunteers in three injections of 2,000 million, 4,000 on, and 4,000 or 8,000 million cocci at weekly intervals. e doses rarely caused more than the mildest local and ral reactions. Exceptionally a more severe reaction asized the presence of an unusual individual suscepti- to the vaccine. In such instances the symptoms were rt those of meningeal irritation and sometimes simulated onset of meningitis. Specific meningococcus agglutinins demonstrated in the blood serum of vaccinated men as pared with normal controls. Moreover, agglutinins were onstrated in the blood serum of chronic carriers of the ngococcus. Evidence is thus brought forward that the ive immunity of chronic carriers to epidemic meningitis be due to the presence of specific antibodies in the d stream.

Origin of Tumors in Mice.—The results of these inves- ions confirm the previous conclusion reached by Lathrop Loeb that in the majority of the crosses observed, the er rate is either intermediate between those of father nother strain, or that it follows the tumor rate of the t with the higher rate and only in a relatively small ıer of instances the cancer rate follows that of the at strain with the lower tumor rate. On the whole, the dity of cancer rate and cancer age follows the blending of hereditary transmission.

. **Opsonic Activity of Fresh Normal Serum.**—The phago- activity of antimeningitis serum was found most ked while the serum was fresh and active; after heating er the addition of 0.2 per cent. tricresol to a serum by standing at room temperature for four days or he phagocytic activity was diminished to a considerable due, presumably, to the loss of labile opsonin or Fresh normal human and guinea-pig serums defined amounts of opsonin for virulent menin- dilutions as high as 1:16 or 1:32; as a gen- serum has a higher opsonin content than The serums of different persons and found to vary to a slight extent in opsonic ition of fresh normal *human* or guinea-pig antimeningitis serums as prepared and stration, was found to definitely and opsonic activity for various strains of cerebrospinal fluid in meningococcus free of complement or contains but spinal fluid is always free of this ewise, of opsonin for meningococci the opsonic activity of antimenin- an index of its curative power, it conclude that fresh *normal* human lone may possess curative properties relation with meningococci and that the addition of either these normal serums and particularly fresh human serum to antimeningitis serum, as secured in the market, increases opsonic activity. It would appear worthy of clinical test to add 1 c.c. of fresh sterile human or guinea-pig serum to each 9 c.c. of antimeningitis serum, before intraspinal injection and particularly in the treatment of severe and serum resistant cases of meningococcus meningitis, for the purpose of increasing the phagocytosis of the micro-organisms.

68. **Bactericidal and Protective Value of Fresh Normal Serum.**—The bactericidal activity in vitro of different antimeningitis serums was found to be quite low. Fresh or active antimeningitis serums were somewhat more bactericidal than the same serums after inactivation by heating at 60 C. for thirty minutes. Active normal human and guinea-pig serums are generally slightly bactericidal for meningococci. The bactericidal activity of horse antimeningitis and normal human and guinea-pig serum, is largely independent of complemental bacteriolysis. The addition of active normal human and guinea-pig serum to antimeningitis serum sometimes increased the bactericidal activity of the latter. Whole human and guinea-pig blood found slightly more bactericidal than the serums alone. Normal human and guinea-pig serums frequently agglutinate meningococci in final dilutions up to 1:4, but not in higher dilutions.

Antimeningitis serums containing the largest amounts of agglutinin were found to possess most opsonin and apt to prove most bactericidal in vitro. Normal active *human and* guinea-pig serums were practically without demonstrable protective value in mice infected with virulent meningococci, although the addition of these normal serums to antimeningitis serum appeared in some experiments to slightly increase the protective power of the latter. Since it would appear that a large part of the curative properties of antimeningitis serum is to be ascribed to the presence of opsonin, it is suggested as worthy of clinical trial to *complement the antimeningitis* serum by the addition of active human or guinea-pig serum prior to intraspinal injection and particularly in the treatment of severe and serum resistant infections.

69. **Meningococcidal Activity of Blood.**—Bactericidal tests with a strain of virulent normal meningococci and the blood *of adult* white mice, adult rabbits and young and older guinea-pigs, have shown that the blood of rabbits possesses most bactericidal activity; the blood of old guinea-pigs was found somewhat more bactericidal *than the* blood of young guinea-pigs and white mice. The blood of young guinea-pigs was generally slightly more bactericidal than the blood of adult white mice. In the virulence tests consisting in the intraperitoneal injection of the same culture in graded doses and according to body weight, rabbits were found most resistant; young guinea-pigs were about as susceptible as adult *mice* while older guinea-pigs were somewhat more resistant than either.

The results of these experiments indicate therefore, that there is a general parallelism between *the* meningococcidal activity of the blood and resistance to meningococci and that at least one factor *in* natural immunity to the meningococcus is the presence of *bactericidal* substances in the blood. The results of these studies indicate that the meningococcidal activity of blood of *children is* somewhat less than that of adults; the bactericidal activity *of the latter is* comparable to the meningococcidal *activity of the blood* of mice and young guinea-pigs. It is probable that *certain* persons possess sufficient natural immunity to the meningococcus to afford protection *against meningitis* and it is highly desirable to discover a simple and accurate clinical test or measure of this resistance comparable to the Schick test for antitoxic immunity in diphtheria, as a *means for* encouraging active immunization with meningococcus vaccines; the bactericidal test as described while being simple and fairly *rapid* does not meet these requirements by reason of the possibilities of error and variation. though it possesses definite value as a strictly laboratory procedure *in special* investigations.

70. **Production of Antipoliomyelitic Serum.**—Rabbits could not be immunized with poliomyelitis virus to produce serum which could *restrain* or neutralize the effect of the virus

72. **Cells and Blood Plasma Resistant to Toxins.**—Suzuki has been able to show definitely that the natural immunity of rats for diphtheria toxin and chickens for tetanus is due to two factors—a special resistance of at least certain of the cells of these animals and further to the existence of neutralizing substances in their plasma. The plasma of these animals protects not only the cells of these animals against lethal doses of toxin but it also protects the cells of susceptible animals. So far heart muscle and ovary or in other words connective tissue cells have alone been studied. A sufficient number of experiments have not been made to give quantitative results.

101 History of Base Hospital, Camp Sherman, Chillicothe, Ohio C. A. Wood.—p. 445. Concluded.

97. **Medical Work with Expeditionary Forces.**—Osgood states that the three professional divisions therefore which are represented by their specialists in the combat divisions are genito-urinary, psychiatry and orthopedic surgery. If the cases reach the evacuation hospitals within ten or twelve hours of receipt of their wounds, it is possible to perform primary, delayed primary and secondary suture on nearly 90 per cent. The quick return of the wounded to the evacuation hospital, where the most skilled surgical service can be rendered, thus diminishes the surgery done in the field hospitals and limits it practically to emergencies only. The wounded men with fractures are coming back in splendid shape to the evacuation hospitals. Thus far the splinting has been excellent. In times of push of course the necessity of moving back cases very quickly prevents such a high percentage of early closures from being attained as is possible in times of comparative quiet.

When the cases can safely be removed from the evacuation hospitals, they go back either to the base hospitals of the advanced zone, the special hospitals of the advanced zone, or sometimes directly to the base hospitals of the intermediate and base zones. The special cases of bone and joint injury are segregated so far as possible and sent to special bone and joint hospitals. One is already established in the advanced zone and several others in the intermediate and base zones. In the advanced zone there are also special psychiatric and genito-urinary hospitals. From the base hospitals in the advanced zone, cases of amputation are sent to a special center and segregated. There the early treatment for weight bearing is begun. There are gradually being established, in orthopedic centers, curative workshops. A certain amount of very simple mechanotherapeutic apparatus is installed in these centers.

Every one who comes in contact with the severely wounded soldier, who has been through hardships and suffered and has emerged in a more or less crippled condition, recognizes the importance of beginning, as soon as possible, to combat the idea of crippledom and to awaken and foster a spirit of future usefulness. If at this stage the soldier can be given something to do with his hands and to occupy his mind as well, and he can come in contact with a simulating personality who is not a soldier and who will not talk battles with him, he gains comparatively quickly the conception of a possible wage-earning capacity and a return to a useful place in the body politic. He recognizes that his duty to the nation does not end with the end of his fighting and that his disability is a disability to be overcome.

99. *Empyema at Camp Lewis.*—Pneumococcus empyema was treated successfully at Camp Lewis by rib resection and simple drainage. From the progress of the yet incomplete cases (final results will be reported later), Rockey feels that the most efficient method of treating streptococcus empyema has been by thoracotomy, with constant negative pressure. This is shown by: (*a*) absence of mortality; (*b*) smooth postoperative convalescence, except in cases of too early removal of drainage tubes; (*c*) absence of pneumothorax, as proved by roentgen ray; (*d*) economy of materials and labor.

120. **Sodium Citrate in Pneumonia.**—Weaver says that it is highly probable that some who have tried this treatment and have been disappointed in its results have not given the citrate in large enough doses. In an adult, 40 to 60 grains every two and a half to three hours, must be continued day and night until the lung has entirely cleared. If the citrate is discontinued before complete resolution there will be an immediate relapse. This relapse will again clear away under the influence of the citrate. This will be absolute proof that the citrate is responsible for the recovery by lysis. Thirty-six cases have thus far been treated and a rapid recovery has resulted in each instance.

124. **Anti-Influenza Vaccine as Prophylactic.**—Park says that as the investigations have proceeded in Boston, New York, and elsewhere, it has become more and more probable that the primary cause of the disease is the influenza bacillus and that the complicating infections, due to the streptococci and pneumococci, are superimposed. It is fair to assume that the strain of the influenza bacillus responsible for this epidemic is an especially virulent one differing somewhat from the strains previously in Park's midst. The streptococci and pneumococci may be communicated from the sick with the influenza bacillus or they may have been present for some time before the attack. The influenza bacilli have been found in almost every case of clear cut infectious influenza. In the complicating pneumonias, they have been found associated with either the streptococci or pneumococci. In one case the bronchopneumonia was due entirely to the influenza bacillus. The results of the Department of Health of the City of New York, in fact, have closely agreed with those reported from the United States Naval Hospital at Chelsea, Mass., by Dr. J. J. Keegan, in THE JOURNAL, Sept. 28, 1918.

2. **Rickettsia Bodies in Lice and Trench Fever.**—The constant presence, after a suitable lapse of time, of rickettsia bodies in lice which have been fed on a trench fever patient has been confirmed by Arkwright and Duncan. The absence of rickettsia bodies from lice bred in captivity and fed only on healthy men has been shown by them. A very close correlation has been shown to exist between the presence of rickettsia bodies in lice or the excreta of lice and the virulence of these materials when inoculated into men.

3. **Employing Expectant Mothers in Munition Factory.**—Since the outbreak of the present war the numbers of married women of child-bearing age who have entered into industrial employment have steadily increased. Apart from the necessity for engaging in well paid work experienced by these women, various industries have discovered that these married women are valuable servants, who are reliable workers in different processes and who cannot always be replaced by satisfactory substitutes if they leave work. Up to a recent date there has been no fixed routine of procedure in dealing with women factory employees who have become pregnant. In some instances the condition has been ignored and the woman has been allowed to work at any process as long as she has wished to do so without any regard to the suitability of the work on which she is engaged. In other cases the custom has been to dismiss an expectant mother directly her condition becomes apparent regardless of the question of her ability to work to a later date.

The prematernity scheme in Leeds was opened for the transfer of women in April, 1918. The women themselves apply at each factory to their welfare supervisor to be enrolled for employment under the scheme. They fill in a form of application, and sign an agreement to accept the wages offered for this class of work. This form is forwarded to the lady superintendent in charge of the scheme, who notifies the factory medical officer of the applications. The factory medical officer examines all applicants as soon as possible, and sends in a report on them as to date and number of pregnancy, date of expected labor, complications if any, and the grade or work for which they are then suitable, and the desirable dates for transfer to lighter work. From this tabulated list of applicants the lady superintendent of the scheme is able to transfer women to their special work as they become eligible provided there is a vacanacy by the delivery of women further advanced in pregnancy working under the scheme. Women on becoming pregnant are very adversely affected by night work apart from any degree of heaviness. For this reason the aim of the scheme is to place expectant mothers on day work only as a routine at the end of the fourth month of pregnancy, and sooner than this date if there is a complaint of great discomfort due to night work. As soon as these women notify their pregnancy, even though they have not reached the end of the fourth month, they are removed from any work involving heavy lifting or sudden strain.

On reaching the end of the fourth month of gestation, or earlier if there is any medical reason, these women are transferred to light sedentary work at a factory engaged in the gaging and assembling of fuse parts. They work from 7:30 a. m. till 5:30 p. m., with the usual factory breaks for meals. They are given the less skilled operations in this factory, as it is not worth while devoting much time to teaching them any work at which they will be employed only a few months. They are paid at the ordinary standard rate for their work. At the end of the seventh month, or earlier if there is any medical reason, these women are transferred from the fuse factory to a department which for convenience is described as the general clothing store and sewing dépôt. Here they work from 9 a. m. till 5 p. m., with breaks for meals as in the factory. They are engaged on the making and mending of the overalls, caps, trouser suits, gloves, etc., supplied by the factory management for the use of their workers. The last hour of the day is given up to the making of clothes for the baby under the help and guidance of the sewing dépôt forewoman. They are encouraged to lie down in the rest room during part of their dinner hour, and at any time if they are temporarily indisposed. The women make their own arrangements for attendance during confinement. They may remain at work until labor begins, if they wish to do so.

6. **Boot Heels Cause of Flatfoot, Soldier's Heart, etc.**—In a normal barefooted man the balance of the body is so perfect that practically no effort is required to keep erect. The weight rests on the heels and outer sides of the feet, not on the arch or inner sides of the feet. Fairweather says that if the heels are raised from the ground by boot heels even a quarter of an inch thicker than the soles the outer side of the foot is removed from the ground and the weight falls on the arch. The center of gravity is also thrown forward, and in a man of 5 feet 7 inches the head is thrown 9 inches off the vertical by a heel three-quarters inch high. To remedy this, and to prevent falling forward, the back muscles and the extensors of thigh and foot come into action. The peroneus longus and brevis, while extending the foot, also evert it, and the tibialis anticus, which supports the arch and inverts the foot, gets elongated and ceases to act. A soldier, 5 feet 7 inches, weighing 154 pounds, and wearing a heel three-quarters inch thicker than the sole, has to exert strength enough to be constantly lifting 56 pounds, from the ground in trying to retain his balance. In a man loaded with 60 pound equipment this means that he has to support to 116 pounds, nearly doubling the weight he is supposed to carry.

Fairweather is convinced that this is doubtless one factor in the etiology of soldier's heart, as every heart, even if healthy, is not equal to this strain. To preserve the lumbar curve without overtaxing the back muscles women are obliged to use corsets. The use of waist belts by men is similarly explained. The waste of neuromuscular energy in retaining an erect posture when wearing heels is vary great, and must play a large part in producing hysteria, neurasthenia, and possibly refraction troubles. Heels are also partly responsible for hammer toes, the long flexors of the toes being supplied by the same nerve as the calf muscles, and getting spastic with them. Fairweather thinks sprained ankles, the stoop of old age, asthma, varicose veins, weak back, and spinal curvature may also be partly due to the effect of heels.

A rational boot should have the soles and heels of the same thickness. Under the arch of the foot the sole should be curved with a convexity upward, but not so convex as to cause pressure on the sole. The leather could be reinforced by spring steel from the heel to the ball of the foot. The inner edge of the boot should be straight, so as to allow the big toe to be in line with the inner side of the arch, as in American boots. In hopeless cases of flatfoot a boot with no heel will at least be more comfortable than the present day boot. The spastic calf muscles will not relax immediately the boot heels are discarded, and consequently at first some awkwardness will be felt in walking. Very soon, however, the tibialis anticus develops, the ankles get stronger, the legs straighter at the knees, the foot gets shorter as the arch recovers, and any tendency to eversion disappears. The figure gets more erect, the chest capacity increases, and walking becomes a pleasure, and as the neuromuscular energy (wasted in neutralizing the forward tilt caused by boot heels) becomes conserved, the health, strength and stamina improve.

17 *Typhus. Weil-Felix Serologic Test. C. M. Craig and N. H. Fairley.—p. 385.
18 *Intestinal Protozoal Infections. D. L. Mackinnon.—p. 386.

14. **Lice-Borne Diseases and Disinfection.**—Hunter describes in detail the use and construction of two new types of Van disinfectors, following this up with the results obtained in Serbia and in Saloniki as he has already done for the Egyptian campaign.

15. **Embarkation and Boat - Distribution Scheme.**—The object of Hemsted's scheme is to segregate patients on embarkation according to diseases, nationalities, ports of debarkation, etc., and to furnish each man immediately with a ticket for his life boat. The Graphic System is adopted and works admirably.

17. **Typhus: Weil-Felix Serologic Test.**—Craig and Fairley claim that this agglutination test is an invaluable aid in the diagnosis of typhus. Frequently the reaction appears only in the disease, and, as a rule, rapidly increases in titer. A rapid agglutination in a dilution of 1/10 on Garrow's agglutinometer, while not absolutely reliable, is sufficiently suspicious to justify the isolation of the case. This is especially true of persons uninoculated with T. A. B. or cholera. The serum of fifty uninoculated natives failed to give a reaction even in a dilution of 1/10. If the test be repeated at intervals of two days confirmatory evidence will, in the great majority of cases, be obtained. This test is particularly valuable in the case of natives in whom it may be difficult to distinguish clinically between severe relapsing fever and typhus.

18. **Intestinal Protozoal Infections.**—From May, 1917, to March, 1918, 1,680 cases (914 dysenterics and 766 nondysenterics) were examined by Mackinnon for intestinal protozoa. Only 131 had less than six examinations. Thirty-four patients had never been out of England. The rest, with very few exceptions, came from France. But it was found that 447 had at some time been in tropical and subtropical countries. Eight hundred and sixty-four, or 51.4 per cent., were infected with protozoa. *E. histolytica* was found in 209 cases, *E. coli* in 440, *E. nana* in 303, *Giardia intestinalis* in 226, *Chilomastix mesnili* in 85 and *Trichomonas hominis* in 13. The 914 dysenterics yielded 123 carriers of *E. histolytica;* the 766 nondysenterics yielded 86. Among 447 persons (dysenteric and nondysenteric) who had been in the East, 72 were infected with *E. histolytica;* of 1,233 persons from England, France and northern Italy, 136 were infected. Two hundred and eighty dysenterics who had been in the East had among them as many as 56 carriers, whereas 634 French and English dysenterics yielded only 67. Of 131 carriers who were treated for twelve days with emetin bismuth iodid, 69 relapsed after a first treatment. Of 16 who went on to further treatment, 8 were eventually cleared. At least 58 per cent. of the relapses took place in the first week. Observations on 5 cases of *lamblia* dysentery treated in France with methylene blue and declared free of the organism do not suggest that this is an effective treatment.

26 *Cancer of Upper Esophagus. E. Cottin and C. Saloz.—p. 689.
27 Colon Reactions. F. Moutier.—p. 697.

24. **Intestinal Bilharziasis.**—Carnot gave daily enemas of thymol in an oil emulsion and gave thymol also by the mouth, with good results in the two cases reported.

25. **Test for Strength of Gastric Digestion.**—Meunier has the patient swallow a pearl of ether, enclosed in a little rubber bag, the neck of the bag tied with a cord of some substance which is digested by gastric juice. When this cord yields to the digestive juices, and the sac thus spreads open, the ether escapes and the patient belches. The length of the interval that elapses between the swallowing of the pearl and the characteristic eructation is an index of the strength of the digestive forces. He used catgut at first to tie the sac, but found *filandre* cord better for the purpose. This *filandre* is made like ordinary catgut from the small intestine of sheep, but whereas catgut is made from the third layer, next the mucosa, the *filandre* is made from the second, the purely muscular tissue layer. This permits more even digestion. The ether pearl is tied in the center of a disk of thin rubber tissue, about 3 cm. in diameter. This is drawn up and held by a fine elastic drain, the ends of which are tied together with the strip of *filandre*. As this yields to digestion by the gastric juice, the ether pearl falls out; as it bursts, the patient feels a peculiar sensation and belches the ether. Taken with an Ewald test meal, the ether eructation occurs in normal conditions in fifty or sixty minutes. Meunier is convinced that the findings with this test are more exact and reliable than with chemical tests, as the latter require the stomach tube, and the information derived from it applies only to that special moment. A series of intubations would be instructive, but this would certainly modify the motor functioning of the stomach and thus secondarily modify gastric secretion. The ether pearl, on the other hand, swallowed with the meal, undergoes digestion along with the food, and gives the warning signal only when the digestion has reached a certain stage. It is thus a true physiologic index.

26. **Cancer of Upper Esophagus.**—Cottin and Saloz remark that the laryngeal form of cancer of the esophagus is the one hardest to diagnose. The dyspnea, the attacks of suffocation, point to the air passages. The intense pain from pressure on the brachial plexus and sympathetic nerve may suggest angina pectoris, while the partial or total aphonia or dysphonia suggest primary laryngeal disease. The diagnosis generally has to be made by exclusion. In a case described, spasms of coughing and of increasing dyspnea were the only symptoms at first. In four months the voice was bitonal, and eating brought on paroxysms of coughing. There was paralysis of the left recurrent nerve, and the disturbances were attributed to this at first, but, by exclusion, the attention was finally focussed on the upper esophagus, and necropsy confirmed the assumption of malignant disease at this point.

Aug. 13, 1918, **80**, No. 32

28 *Influenza. F. Bezançon.—p. 158.
29 *Scarlatinal Endocarditis. P. Nobécourt.—p. 162.
30 Polymicrobian Antigonococcus Vaccine. G. Baril.—p. 164.

28. **Influenza.**—Bezançon states that the pneumococcus is decidedly the predominant microbe in the prevailing epidemic of influenza at Paris. The frequency and the severity of the bronchopulmonary complications are striking, and also the number of cases of zona that have followed it. In one hospital there were over twelve cases of influenzal herpes zoster in one month.

29. **Scarlatinal Endocarditis.**—Nobécourt ascribes to secondary infections the ulcerative and vegetative forms of endocarditis in scarlet fever. The scarlatinal virus alone induces a simple nonulcerative endocarditis, and this is the more common. Among the soldiers he encountered it in 2.5 per cent. of 278 cases of scarlet fever. The heart was affected, as revealed by auscultation, in 38.5 per cent. of the cases of scarlatinal rheumatism in soldiers. As a rule, scarlatinal endocarditis tends to recovery, the auscultation findings becoming normal once more. It passed into a chronic phase only in two of seven cases in soldiers. The myocardium seems to be left with a tendency to ready dilatation later. Tardy tachycardia is not infrequent. The endocarditis of scarlet fever is thus closely analogous to that of acute rheumatism. With both there are liable to be acute polyarthritis, pericarditis, etc., and, in children, chorea.

Bulletins de la Société Médicale des Hôpitaux, Paris

June 28, 1918, **42**, No. 23

31 *Tuberculosis of the Heart. Braillon.—p. 668 and p. 669.
32 *Serodiagnosis of Spirochete Jaundice. Martin and Pettit.—p. 672.
33 *Aortic Insufficiency. F. Trémolières and L. Caussade.—p. 675.
34 *Oliguric Heart Disease. O. Josué and M. Parturier.—p. 682.

38 *Epilepsy. Mirallié.—p. 697.
39 Paratyphoid A. De V. de Lavergne and C. Gautier.—p. 700.

31. **Tuberculous Heart Disease.**—Braillon comments on the clinical picture of subacute tuberculosis of the endocardium, the valvular disturbance, mitral rhythm and progressive asystole, in young subjects, with a febrile temperature during the months before death, the fever of the tuberculosis type. The clinical picture differs essentially from that of streptococcus protracted endocarditis, and animals inoculated with blood developed tuberculosis in the two cases analyzed (both previously published).

He discusses further the simple endocarditic phlegmasia, with tubercle bacilli, which is the form of cardiac tuberculosis that develops in the resistant or with mild infection. Under other conditions, the bacilli are arrested in the capillaries and the miliary form of tuberculosis develops from the specific embolisms. In short, he concludes, tuberculosis must be regarded as a cause of chronic heart disease, possibly of as much importance as acute rheumatism and syphilis.

32. **Agglutination Test for Spirochete Jaundice.**—Martin and Pettit report that the Widal test applied to human icterohemorrhagic spirochetosis during the last six months has given conclusive findings from the clinical standpoint. Normal and syphilitic serums have never to date agglutinated these spirochetes, while the course of the case, the spirocheturia and inoculation of guinea-pigs confirmed the positive findings. The earliest date in which the agglutination test proved positive was the tenth day, but the agglutinins long persist in the blood, up to twenty-two months to date in one case, still agglutinating at 1:1,000. The immunisins do not appear till the fifteenth day.

33. **The Murmur of Aortic Insufficiency.**—In 50 per cent. of 82 men with aortic insufficiency examined, the murmur was heard in the left second and third interspaces, and only in 11 in the right second interspace; in 20 at the sternum; in 9 at the xiphoid appendix and once toward the apex. The cases in which it was heard at the left were all recent ones. With an old aortic lesion, the diastolic murmur is heard on the right side, and radioscopy shows hypertrophy of the left ventricle with dilatation of the right cavities and deviation of the axis of the aorta upward and toward the right. The mechanism of this is explained with diagrams. In the recent cases, with left murmur, the left ventricle is simply hypertrophied, the aorta still vertical. In a little more advanced stage, the murmur is heard at the sternum, and the aorta has begun to slant toward the right.

34. **Oliguria of Cardiac Origin.**—Josué and Parturier report a typical case which confirms that myocarditis is able, alone, to induce oliguria with such retention of fluids in consequence that there is pronounced dropsy. The latter resembles that of renal origin, but the kidneys are sound. The trouble is

merely that the heart cannot pump the fluid to the kidneys in sufficient amounts. A drop in the output of urine is the capital symptom which should suggest a failing myocardium. Even if the kidneys are diseased, the heart may be mainly responsible for the oliguria. The proof for these assertions is provided by the rapid subsidence of the dropsy under digitalis alone.

35. **Latent Microbism.**—In one of the two cases described, latent infection in a war fracture flared up two years after it had healed. The staphylococcus and an anaerobic streptococcus were responsible for it. In the second case the interval was twenty-three months, and the staphylococcus and streptococcus found were facultative anaerobes.

36. **Lethargic Encephalitis.**—The aviator of 26 was taken suddenly with headache and torpor. The somnolency was almost continuous, and strabismus and ptosis varied from day to day. For a few days there was hemiplegia and one day clonic movements, but no fever at any time. Lumbar puncture showed limpid fluid, apparently normal except for slight lymphocytosis. The symptoms gradually subsided and complete recovery now impends; the tendency to somnolency persisted for eighteen days, with intermittent headache.

38. **Epilepsy.**—Mirallié insists that salt should be discarded absolutely as also tea, coffee and alcohol. Then the doses of bromids can be materially reduced, and such improvement may then be realized that it amounts to an actual cure. He gives a moderate dose of the bromid every day, without interruption. When his patients go thus two or three years without a seizure, he reduces the dose of the bromid, but emphasizes that absolute abstention from salt is the main thing. In his first series of 181 cases, only 83 followed his instructions. At that time he ordered merely restriction of salt. In 12 cases the results were negative; in 18 there was improvement and 53 had no further seizures. Since 1912, 52 of a later series of 133 cases followed instructions, and 31 have had no further seizures and 18 have been much improved; more or less benefit has been realized in all but 3 cases. Of 10 men in one institution, all were improved and 5 apparently cured, as also 9 of the 12 women, all showing marked improvement. The youngest of the clinically cured was 7, the oldest 63 years of age. The seizures in one case had been frequent from the age of 7 to 37, but there have been none since this treatment was instituted. The best results were realized in families in which the mother did the cooking, and she was able thus to keep all salt out of the bread, the butter, etc. When this was left to servants, the salt was not banished so rigorously. Full success was realized only in the cases with absolute abstention from salt, tea, coffee and alcohol. Sugar, pepper, vinegar and lemon juice were allowed freely. The benefit was prompter and more pronounced in persons who had previously used much salt. The other symptoms of epilepsy were not modified so early as the actual seizures. The diet, except for the salt and stimulants, can be varied and liberal, but must be served entirely without salt. The failures were always in the wealthy homes.

Journal de Radiologie et d'Electrologie, Paris

March-April, 1918, 3, No. 2. Pub'd August

40 *Mute Tuberculous Cavities in Lung. J. Aimard.—p. 49.
41 *Roentgen Examination of Spondylitis. Péhu and Daguet.—p. 53.
42 *Localization of Deep Projectile. L. Patte.—p. 57.
43 *Bulletin of Radiologic Service.—p. 65.

40. **Mute Tuberculous Cavities.**—Aimard gives the roentgen findings in a number of cases in which there was nothing to suggest a cavity in the lung otherwise. A silent cavity in the left lung is usually at the apex; in the right lung it may be found at the apex, base or middle of the lung. When the outline is distinct, in clear lung tissue, the cavity is of a fibrous type. An active cavity may show a hazy outline in the midst of infiltration. The outline of an arrested cavity usually grows more and more indistinct until the outline quite disappears. With sclerosis and consequent deformity of the superior interlobe, a shadow may be cast suggesting the floor of a cavity, ribs aiding to form an outline resembling that of a tuberculous cavity at the right apex.

41. **Deforming Spondylitis.**—Roentgen study of six cases seems to show that chronic spondylitis with tendency to ankylosis, and rhizomelic spondylosis seem to be different forms of chronic rheumatism. The two dorsal and first two lumbar vertebrae are usually first and predominantly affected.

42. **Localization of Deep Projectile.**—The method described is based on the use of a small diaphragm and measured rotation of the tube.

43. **Army Roentgen Bulletin.**—This section contains reports of a number of cases interesting from the roentgen standpoint, and a number of modifications in roentgen technic worked out by radiologists in the service. They include twin tubes for locating projectiles, a pedal control for rotating the tube, a simplified table for roentgen work, supplementary diaphragms, etc.

Paris Médical

Aug. 3, 1918, 8, No. 31

44 *Lethargic Encephalitis. A. Netter.—p. 81.
45 *Meningococcemia. P. Sainton.—p. 86.
46 Partial Tetanus. G. Étienne.—p. 91.
47 *Malaria and Malariosis. Aynaud.—p. 95.

49 General Vaccination against Typhoid. H. Alliot.—p. 100.
50 Poliomyelitis in the United States. G. and J. Blechmann.—p. 105.

44. **Epidemic Lethargic Encephalitis.**—Netter gives a detailed history of this disease which he has encountered in ten adults and four children in his private practice and in six children in his service in a children's hospital. In the 105 cases in England, sixty-four were in adults, over 20, and only fifteen were in children under 10. He insists that the clinical picture is not that of a food intoxication nor of a special form of influenza nor of poliomyelitis. He reiterates that it is a *maladie autonome*, the specific agent of which is endowed with an affinity for the nerve centers. The epidemic began simultaneously in France and in England late last January. The normal findings in the cerebrospinal fluid are important for the diagnosis. All the features of the present epidemic are found in the accounts of an epidemic at Vienna in the winter of 1916-1917. An apparently similar epidemic was reported in the *Medical Journal of Australia*, March, 1918. In comparison with poliomyelitis, the mortality is greater, but integral recovery is more common than with poliomyelitis; the cerebrospinal fluid is more nearly normal. In poliomyelitis, he says, the symptoms are almost exclusively bulbar and protuberantial, and the nerve cells are found more pathologic, although the microscopic changes are not essentially different in the two diseases. In treatment he relies on hexamethylenamin, giving 1 or 2 gm. in the twenty-four hours. He has had no opportunity yet to give intraspinal injections of convalescent serum such as have proved effectual in poliomyelitis.

45. **Meningococcemia.**—Sainton describes seven different forms which meningococcus infection of the blood may assume: the fulminating or subacute form, the typhoidal, pseudomalarial, eruptive, articular and metastatic form, and the abortive forms. Herpes is frequent in meningococcus infection. In dubious cases the turbid spinal fluid may give the clue even in the absence of meningeal manifestations. In one case described, the meningococcemia dated from May 6, but meningitis did not develop till July 14. The danger of contagion of others in such a case is obvious. In the pseudomalarial form, the man may come and go freely during the free period between attacks, and thus sow the germs broadcast. Intravenous injection of antimeningococcus serum seems the logical treatment, but there is sometimes a dramatic reaction that might prove fatal. Artificial respiration, venesection and injection of ether were all that saved one of Sainton's patients in such a case. Similar experiences have been reported by Netter and by Marie, so that the intraspinal or subcutaneous route seems preferable.

47. **Malariosis.**—Aynaud warns that the suggestion exerted by actual injury from an accident or actual malarial disease, plus the talking it over with one's mates, may generate a state of mind in which the accident or the malaria—any accident, any malaria—is regarded as synonymous with indemnity. Soldiers who have had malaria and who get this

"malariosis" are all convinced that they have the absolute right to be exempted from further service to the end of the war, and to be supported after the war. When they are dismissed from the hospital they are told to keep on taking quinin. This means, they think, that they are not cured. If not cured of a disease contracted in the service, then they have a right to be taken care of. At present all they demand is exemption from further service, but the day that peace comes they will claim a pension for disability contracted in the service, and they will present a bunch of hospital cards, etc., with mention of malaria, anemia, etc., often written merely at the man's own dictation, without special examination. Army medical officers must beware of breeding this "malariosis" with its train of pensions and life-long loafing. Men with malaria should be under the care of experts in malaria, and when dismissed they should not be told to continue taking quinin. Every time a man with malariosis comes into the hands of a physician who is not a malaria specialist, the man returns to the hospital for a course of treatment, and always he seeks a different hospital. Malariosis is becoming seriously prevalent, and both medical and military measures are necessary to stamp it out.

Presse Médicale, Paris

Aug. 29, 1918, **26**, No. 48

51 *Access to Heart. P. Duval and H. and P. Barasty.—p. 437.
52 *Clinical Tests of Labyrinth. H. Piéron.—p. 439.
53 *General Anesthesia by Intubation. Guisez.—p. 441.
54 Histochemical Constitution of Pus. A. Demolon.—p. 443.
55 Mercury-Lead Plaster. L. A. Longin.—p. 445.

51. **Median Pericardotomy.**—Duval and Barasty show with illustrations the various methods of access to the heart and the large vessels at the base of the heart. They expatiate on the advantages of a median technic with which the upper end of the sternum is cut across and the body slit lengthwise. The incision is thus in the shape of a T, but the access thus afforded to the mediastinum and upper abdomen is surprisingly extensive as the halves of the sternum are turned back. This bone is of such a spongy nature that it grows together at once without suture, so that this median thoraco-abdominal pericardotomy seems to be the best means of access to this region.

52. **Clinical Tests of Labyrinth Functioning.**—Piéron cites the general laws which govern labyrinth functioning, and describes the mechanism and interpretation of the findings in different pathologic conditions.

53. **General Anesthesia by an Intratracheal Tube.**—Guisez remarks that the advantages of administering the anesthetic through a rubber tube are so great that it has proved possible to materially modify the technic of operations on the face and neck. He has applied it in 330 cases, and there has never been the slightest by-effect from the intubation. An olive tipped sound, No. 26 to No. 30, is introduced by one skilled in direct laryngotracheoscopy, the patient under the influence of a few whiffs of the anesthetic. A spinal spring is wound around the sound where it passes between the teeth, and the sound is pushed in about half way down the trachea. A string fastened to it and tied around the neck holds it in place, and a sponge is packed around it in the nasopharynx. As there is no possibility of blood and secretions getting into the air passages, there is no need to hold the head far back. One unexpected advantage of this technic is the absence of postoperative nausea and vomiting. Only six of the 330 patients had any tendency to vomiting, and in these it was slight; the preoperative first whiffs of the anesthetic were probably responsible for it. These experiences demonstrate that postoperative vomiting cannot be ascribed to a toxic action on the liver. It seems more rational to ascribe it to swallowing of chloroform fumes and of saliva saturated with them. When this is prevented, there is no vomiting. Under the influence of any toxic gas, constant swallowing movements are kept up, asleep or awake, and the swallowed air and fumes amply explain the distension of the stomach walls and irritation of its mucosa. In the gassed, he has found evidences all along in the esophagus of toxic action from the swallowed gas. All of which confirms his assumption that by this intubation technic, preventing all swallowing, we can ward off postoperative nausea and vomiting in the majority of cases, outside of damaged liver and kidneys.

58 Secondary Arterial Hemorrhage. S. Tarantino.—p. 797.
59 Sending Blood for Examination. Domenici.—p. 800.

56. **Adhesive Plaster as Dressing for Wounds.**—Mancini relates that three years' experience has convinced him of the advantages of applying narrow strips of adhesive plaster directly to wounds. They heal under this dressing much faster and better than under gauze dressings, even when the gauze can be kept constantly moist. The strips of plaster are cut long enough to extend for some distance on each side of the wound, and they are drawn tight and pressed down on the wound. Under this combination of pressure, constriction and protection, without any antiseptic, the granulations are held in proper proportions, and the wound heals over fast. The only contraindication is progressing ulceration; under all other conditions, this method has superior advantages, he reiterates. The secretions escape between the strips of plaster. He has seen extensive bed sores heal under this treatment. It acts better when the strips are left unmolested for six or eight or more days. The gauze above can be changed as desired. This plaster treatment has the same protecting action as a paraffin film, but the latter lacks the constriction and pressure possible with the plaster. He uses ordinary adhesive plaster about 2.5 cm. wide. The simplest way to sterilize it, he says, is to leave it in alcohol for a day or two and then burn out the alcohol.

Riforma Medica, Naples

65 Factitious Phlegmons. G. Garin.—p. 361. Conc'n.
66 Instrument to Facilitate Pectoral Fremitus. Fabbretti.—p. 364.
67 *Toxic Gases in Warfare. C. Capezzuoli.—p. 367. Conc'n.

67. **Gases in Warfare.**—Capezzuoli reviews what has been published on this subject, especially the long array of Italian contributions. In conclusion he mentions that Professor Lo Monaco's experiments have apparently demonstrated that chlorin compound gases can be utilized to preserve meat, fish, etc., and may be destined to aid materially in food conservation in normal times. The gases he has been testing are not toxic, and do not modify the taste when used for this purpose. Specimens of tissue from a lung mummified by the war gas took the stains and responded to other histologic tests like normal tissue.

Amazonas Medico, Manaos

March, 1918, **1**, No. 1

68 Finger Prints of Brazilian Indians. G. Ramos.—p. 4.
69 *Nodular Leishmaniasis. A. Da Matta.—p. 13.

70 Fatal Syncope under Chloroform. J. De Moraes.—p. 16.
71 Retrograde Catheterization. T. Beltrão.—p. 23.
72 Ulcerating Granulomas. A. Da Matta.—p. 25.

69. **Nodular Leishmaniasis.**—In Da Matta's case the feet and lower legs were covered with nodules, some of them ulcerating. Some were confluent, and had the "mossy foot" aspect. The pseudoverrucous affection was of several years' standing and had proved rebellious to all other measures but prompt benefit and final healing of all the lesions followed intravenous injections of 1 per cent. tartar emetic, with local application of a 0.5 per cent. solution, and potassium permanganate. Sodium cacodylate was also given between the courses of injections during two months. The cure of the leishmaniasis was then complete; but there is still hypertrophy of the legs, probably from the chronic erysipelas which had developed as a complication.

Annaes Paulistas de Medicina e Cirurgia, S. Paulo

April, 1918, **9**, No. 4

73 *Urinary Stones in Children. R. Puech and Souza.—p. 73. Conc'n.
74 Syphilitic Facial Diplegia. L. Torres.—p. 89.

73. **Urinary Stones in Children.**—Puech and Souza have compiled thirty-five cases in the state of S. Paulo in the course of ten years, nearly all in the families of immigrant colonists. Only 3 per cent. were in girls; none of the children were less than a year old, and the majority were between 3 and 5. Phimosis was apparent in 70 per cent. of the cases. Suprapubic incision is the best treatment, suturing the bladder at once, but not including the mucosa in the suture. There has been no recurrence in any instance after this operation; the only death in the series was due to other causes.

77 *Croupous Inspiration. A. Hinojar.—p. 385.
78 *Enlarged Glands in Child's Groin. V. Juaristi.—p. 400.
79 *Aids to Memory in Infant Feeding. R. Eyzaguirre.—p. 404.

77. **Croupy Respiration.**—Hinojar describes some typical cases to show the importance of search for the often unsuspected cause for the *tirage* or croupy wheezing in a child, instead of assuming diphtheria as a matter of course. A physician called him up one night for intubation of a child with membranous croup, but he found that the suffocation was from the tonsils, and he at once cut out both tonsils, with complete recovery. The removal of inflamed tonsils, he adds, is not such a serious matter as some suppose. The clue in this and similar cases was that the child's crying voice and cough were clear, not hoarse. Another child was being treated for diphtheria but intubation proved impossible, and the child was brought to him. The absence of hoarseness in the infant's crying voice led to discovery of a retropharyngeal abscess and of the absence of false membranes. Another child was brought for tracheotomy on account of extreme dyspnea and *tirage*, but the voice was clear and the *tirage* seemed to be at the base of the thorax. Necropsy confirmed his assumption of tracheobronchial adenitis. A hoarse cough, with crying and speaking voice clear, locates the stenosis below the glottis. A clear cough, with hoarse voice, locates it in the glottis. When the cough and voice are both clear, the stenosis causing the *tirage* is above the glottis, in the pharynx. Stenosis inducing croupy inspiration is almost always in the larynx, and in children is acute.

When there are false membranes, these protect the mucosa of the larynx during intubation. Hinojar insists that under other conditions tracheotomy is more prudent, more certain and less dangerous than intubation, which should be restricted to laryngeal diphtheria. Puncture of the cricothyroid membrane is a procedure borrowed from the veterinarians, using the same trocars and elliptical section, the longer diameter transverse. He reiterates that this takes no more time than intubation, while it is free from its dangers and requires no special technic nor experience. It relieves the patient until the definite tracheotomy can be done. Zorraquin's valve tracheotomy permits free ingress of air but closes against expiration, so that the expired air has to escape through the natural passages. This prevents atrophy, etc., from disuse, while expiration can proceed more forcibly than is possible through the tracheotomy cannula, the vocal cords, etc., yielding more to pressure from below than from above. For these and other reasons stated, this valve tracheotomy seems from the theoretical and experimental standpoint to have numerous advantages, including the partial reestablishing of normal respiration with a positive tension during expiration. This safeguards the heart and lungs. An illustration is given of the valve device, a metal drum with mica disk adapted to the Broca tracheotomy cannula. Hinojar has had no clinical experience with it.

78. **Adenitis in Child's Groin.**—Juaristi says that among his 20 cases of this kind, in 4 the child had been referred to him with the diagnosis of appendicular phlegmon; in 3 others, under the diagnosis of coxalgia, and in 8 others everything had been thought of except the actual affection. The child's gait may deceptively simulate that with coxalgia. In one typical case the 8 months infant seemed to be suffering pain, with fever, but its appetite and digestion were good. Palpation of the contracted abdomen was negative, and no cause for the child's restlessness and crying was discovered until the ninth day, when the left leg was found swollen throughout. This was traced to a phlegmon in the groin, with a chain of five swollen glands.

79. **Calculations for Infant Feeding.**—Eyzaguirre gives the formulas advocated by different pediatrists, based on the age, weight, etc., of the infant. Comby's method seems to be the simplest, namely, to give the child 150 gm. for each kg. of weight, that is, 15 per cent. of its weight. The dilution of the milk is determined by a fraction of which the numerator is the child's age in months, and the denominator is the succeeding month. This for a 1 month child would give one-half milk; 2 months, two-thirds milk; 3 months, three-quarters milk. If this dilution is not enough, the fraction might be modified to a numerator representing the month before and the denominator the actual month of the child's age. A 3 months infant would thus be given two-thirds milk. Under 1 month, one-third milk seems preferable.

85 *Ocular Complications of Typhus. J. de J. Gonzalez.—p. 70.

83. **Comparative Neurology.**—Ochoterena's finely illustrated article describes the microscopic findings in the retina of the horned frog, and discusses the evolution of the eye.

85. **Ocular Complications of Typhus.**—Gonzalez states that he had ample opportunity to study the ocular complications during the great epidemic of typhus in Mexico during 1916 and part of 1917. It spread to the remotest hamlet of the central tableland. In his town, Leon, there were more than 8,000 cases of typhus. All ages were affected, including infants a year old, who previously had been deemed immune. He encountered cases of complications from vasodilatation, from local infection, from toxic action, and paralysis or contracture of the oculomotor muscles secondary to toxic action on the nerve centers or meninges. In other cases, syphilitic lesions developed in eyes damaged by the typhus. Still another complication was necrobiosis of the cornea from disturbance in its nutrition in the course of extremely severe typhus. The cases in this last group all terminated fatally, and nothing proved effectual in warding off this necrobiosis of the cornea. On the other hand, the complications from local infection could be warded off with care, tending the

catarrhal conjunctivitis which inevitably preceded the corneal ulcer. The ulceration was always central, the patients lying in their stupor with lids partly open so that the cornea got dried, the epithelium cracked and infection was thus invited. The eyes should be washed out daily with isotonic saline to ward off conjunctivitis; when it developed, a weak solution of a silver salt always proved effectual in his hands.

Gaceta Medica de Caracas, Venezuela

87 *Spirochete in Rats at Caracas. J. Iturbe and Gonzalez.—p. 158.
88 Relations Between Brazilian Trypanosomiasis and Endemic Goiter. A. Ayala.—p. 160.

86. **Balantidium Dysentery in Venezuela.**—Tagliaferro describes three cases and some negative attempts to transmit the disease to cats. One of Tagliaferro's patients kept pigs, and various data on record testify to the identity of the *Balantidium coli* found in man, in pigs and in monkeys. Rincones remarks that in the rural districts domestic animals often share the family hearth. He says, "The olfactory orchestra of the foods and exfoods disintegrated by the digestive organs of the various domestic animals, fowls, rats and mice under the family roof, runs the whole scale of odors, and like a dirge rises above the promiscuity of these heedless beings all crowded into one room." He adds that 153 cases of balantidiasis are on record in accessible literature, with a death rate of 23 per cent. In conclusion Rincones describes the method of treating coloproctitis caused by ciliated infusoria, as suggested by F. Smithies of Chicago, and he urges a trial of it in balantidium dysentery.

87. **Spirochete of Hemorrhagic Jaundice Found in Rats at Caracas.**—Iturbe and Gonzalez inoculated guinea-pigs with an emulsion of the kidneys of ten rats and of seven rats. One guinea-pig developed typical hemorrhagic febrile jaundice, and spirochetes were recovered resembling in every respect the spirochetes described by the Japanese and the Belgian writers.

July, 1918, **9**, No. 10

92 *Scleroderma or Leprosy? J. Aparicio.—p. 510; I. Rodriguez.—p. 522.
93 *Unclassified Tropical Lesions. P. Martinez and Lopez.—p. 525.
94 *Cocain Local Anesthesia. A. E. Marulanda.—p. 534.
95 Metabolism in Diabetes. E. Gomez.—p. 537.

92. **Scleroderma or Leprosy.**—A case is described over which there has been much discussion, as the patches of scleroderma are accompanied by nervous disturbances remote from these patches. The ulnar neuritis, in particular, does not fit into the scleroderma frame. Aparicio's decision therefore is that the case is an incomplete form of nervous leprosy, and that isolation is not required. Rodriguez reports that five applications of electricity in this case improved the skin patches until the scleroderma had nearly disappeared.

93. **Tropical Pathology.**—Martinez and Lopez give illustrations of two cases in which a large tumor had developed just above the ankle, with a smaller tumor on the other side of the leg. They have encountered a number of cases of these juxta-articular nodules near the ankle, knee or hip joint. They seem to be a torpid fibroma growth, close to a large joint, peculiar to the tropics. An illustration is also given of a type of ulceration on the dorsum of the foot with which there is so much retraction of the cicatricial tissue that the foot is drawn up till severe deformity results. These "retractile ulcers" develop after a trauma, as a rule. The resulting deformity may suggest ainhum, or the deformity from retraction in these cases may be equal to that from an extensive burn of the third or fourth degree. Amputation was required in the two cases illustrated. In a third group of cases the ulcerative process begins between the toes and runs a highly destructive course, the toes dropping off and the destructive process invading the dorsum of the foot. The discharge from it is profuse and fetid, but the tendency to a spontaneous cure excludes malignant disease.

94. **Cocain Local Anesthesia in Abdominal Surgery.**—Marulanda addresses his remarks to physicians in regions without hospitals. He expatiates on the advantages of local anesthesia in these conditions, and especially on the use of cocain for the purpose. In Colombia, the lack of corsets, the numerous pregnancies and the hard manual work of the women favor production of umbilical hernia, and he describes four cases in which he operated for this, under cocain anesthesia, with ease and complete success. Umbilical hernia in women inclined to obesity develops with such alarming symptoms that the physician cannot believe that the hernia alone is responsible for the intense colic pains. They may coincide with digestion, and if the woman has a tendency to neurasthenia, she may experience pains and symptoms which lead the physician widely astray. He warns further that the presence of ascarides is practically certain in the rural districts of his country, and it is almost indispensable to administer a vermifuge the day before the contemplated operation. Otherwise there is liable to be paralysis of the intestine. The inexperienced may feel called on to open up the sutured herniotomy wound, but under 0.2 gm. of santonin all subsides at once. He uses a 1 per cent. solution of cocain, thus anesthetizing a broad zone of the skin.

101 Stenosis of Duodenum. Urrutia.—p. 65.

96. **Secret of Rapid Repair of Gap in Nerve.**—Ramon y Cajal called attention in 1892 to the ameboidism of newly formed nerve fibers seeking the proper direction for bridging a gap in a nerve. Later he became convinced that some substance in the nerve stump attracted the young fibrils, and thus guided them in the right path. He reviews what others have published on this subject, and reports new experimental research. Everything seems to indicate that the substance which attracts the sprouting fibrils is in the cells of the sheath of Schwann. These cells may act effectually whether they are in the nerve graft or in the peripheral stump. But in order to exert this attraction these cells must be alive and actively functioning. The attraction is the more intense the younger the animal and the greater the vitality of the tissues. It seems to be immaterial whether the Schwann cells are in the stump or in the interposed graft, provided their vitality has not been impaired.

An interposed nerve graft obtained and implanted with the minimum of injury of the tissue cells, materially hastens repair over a gap in the nerve, the sprouting fibrils rapidly running down through the graft and penetrating the peripheral stump. There is more in this phenomenon than merely growth along the lines of least resistance. Dead Schwann cells have none of this neurotropic action. Twelve illustrations show the different behavior of the sprouting fibers under different conditions. For example, if half of the sciatic nerve of a kitten is severed, the other half left intact, the new sprouting fibrils are attracted only by the Schwann cells in the peripheral stump, and very few diverge from the axial direction. But if, when the half of the nerve is severed, the other half is slightly cut with the scissors, then the sprouting fibers crowd sideways into the second half, and very few work down toward the peripheral stump. One illustration shows the rapid repair in the sciatic nerve of a kitten thirteen days after the nerve had been resected and the resected segment slit and replaced at once, before it had had a chance to get chilled. The sprouting fibrils after passing through the slit graft were attracted by the Schwann cells in the other half of the graft, and turned back into it. Other fibers wandering around in response to the attraction of the Schwann cells were unable to reach them before making a circuit around the graft. Other illustrations show the good results, although less perfect, obtained with a nerve graft from another species, or with a graft taken from another nerve in the same animal.

100. **Cholecystostomy versus Cholecystectomy.**—Cardenal admits that cholecystectomy is indicated when the gallbladder is inflamed from the presence of stones and the common bile duct is free from obstruction. When the common or hepatic duct is obstructed and this cannot be corrected at once, he advises against cholecystectomy. When the obstruction seems to be permanent, as with cicatricial stenosis, he advises at once an anastomosis between the gallbladder and the stomach or the duodenum. Otherwise he advocates deep cholecystostomy, suturing the gallbladder not to the skin but to the peritoneum. In several cases he has made an opening between the gallbladder and the stomach, and the functional results have been perfect. There was never any disturbance from this emptying of the bile into the stomach. In one case of cancer of the pancreas the patient improved remarkably after this operation, and there were no further disturbances from the biliary apparatus.

109 Toxic Principle of Baccharis. V. Arreguine, Jr.—p. 389.

102. **Heterogenous Hemolysins.**—Sordelli and Fischer review the literature on the subject of the natural hemolysins and especially the hemolytic properties of certain organs in certain animals for sheep and goat blood. They then report extensive personal research for comparison of the characteristics of isogenous and heterogenous hemolysins from this source. The conclusions are given in detail in English, French and German as well as Spanish.

103. **The Ticks of Argentina.**—Over four pages of bibliography and three plates accompany this comprehensive article. Four genera of ticks found in Argentina are described, with or without a shell, including eleven species. Twelve genera of ticks are known in all.

106. **Action of Snake Venom on Proteic Substances.**—Houssay and Negrete tested the action of the venom of different species of poisonous snakes on the various elements of the blood and tissues, on casein and on gelatin. Each venom has its characteristic properties, but all seem to alter the physical-chemical state of albuminous substances, and then digest them later. The proteolytic properties are distinct from the coagulating, agglutinating, toxic and hemolytic properties of the venom. They are much stronger in the venom from certain species than in others.

108. **Modification of Gram Technic.**—Senez relates that precipitation can be avoided by the technic he describes, while the specimens retain their color much better. The diphtheria bacillus, in particular, takes the stain distinctly and uniformly.

The stain is made by triturating 2 gm. of crystal violet, adding 100 c.c. of distilled water and, when entirely dissolved, adding 1.6 gm. of sodium chlorid. When thoroughly mixed, a pellicle forms on the surface and a precipitate is thrown down. This precipitate is collected on a filter paper and dried in the incubator. The powder thus obtained keeps well in small vials, well plugged. To 0.5 gm. of this powder are added 50 c.c. of alcohol at 95 degrees, and the Erlenmeyer jar is agitated until the powder is entirely dissolved, after which 130 c.c. of distilled water are added. There is not the slightest precipitation. After fixation of the specimen with heat, it is then stained with a few drops of this fluid for half a minute. It is then drained off, and the specimen is immersed in the Gram solution until the violet stain veers toward black. Then the specimen is treated with 90 per cent. ethyl alcohol, letting it fall a drop at a time on the slide, held slanting, until it does not wash away any more of the stain. The specimen is then rinsed freely in water, and it is ready for the counter stain or for mounting. The fuchsin counter stain is made in the same way, substituting fuchsin rubina B for the crystal violet. The stains thus made are bright in tint; there is no precipitation with them during the staining procedure, and they keep indefinitely. They can be used to advantage in place of Ziehl's solution for simple staining in general, and for restaining specimens treated by Gram's method. Gram positive bacteria stain a dark violet, contrasting well with fuchsin stained elements.

118 *Malaria in Sumatra. H. N. van der Heyden and Schüffner.—p. 1.

118. **Malaria in Sumatra.**—This entire number is devoted to a study of practical means to combat malaria in a seashore district. The report is profusely illustrated, with photographs and maps showing the exact points where various measures are needed. It is emphasized that the general level of ground water must be kept as low as possible; existing trenches must be deepened, and branching channels provided. The terminals in the sea must have valves preventing inflow of the tides. In all drainage works in the Indies, the engineer must be guided by the biology of the mosquito. For example, the floor of the channels must be so arranged that if they should happen to run dry, there should be no crevices or cavities in the bottom that could retain a little water. No one must be allowed to dig trenches or ditches on his own initiative. The profession in malarial regions should be trained in prophylaxis, and the engineering authorities should consult constantly the local physicians.

MILITARY ASPECT OF STATUS LYMPHATICUS

JAMES EWING, M.D.
Contract Surgeon, U. S. Army
WASHINGTON, D. C.

During the past thirty years it has been the conclusion of many pathologists who have carefully observed the general configuration of the cadaver at necropsy that the fate of the human body is not a matter of chance but in general is controlled by certain intrinsic physical tendencies that are of congenital origin.

This conclusion is merely in line with the doctrine of a constitutional predisposition to disease, the importance of which has been submerged by the advent of the germ theory. Clinical observers, especially in recent times, have not been so much impressed with the importance of constitutional factors doubtless because the most definite evidences of such tendencies are revealed chiefly at necropsy, and possibly also because the modern clinician is greatly occupied by a multitude of laboratory tests and aids to diagnosis and prognosis, which apply without regard to any constitutional basis of disease.

Recently, the experience of the Medical Department of the Army has revealed in a highly impressive way the fact that, under the stress of military life, certain physical factors which escape ordinary physical examination soon declare themselves most emphatically, with the result that numbers of apparently healthy men die, or break down and are incapacitated, and become a burden instead of an asset in the military force. Any one who has the slightest conception of the general factors leading to disease cannot fail to recognize that anatomic defects are chiefly responsible for the recent discoveries of "irritable heart," "irritable thyroid," nervous instability, functional shell shock, etc. It also seems highly probable, and I have some concrete pieces of evidence to show, that in a great variety of conditions the stress of military life is bringing into action the inevitable force of constitutional tendencies in the unexpectedly fatal outcome of many common diseases and traumas.

Since constitutional defects cannot be remedied, it is of practical importance chiefly to inquire whether there is any way in which they can be recognized, and whether there are any means of avoiding their hazards.

In one form of constitutional dyscrasia, status lymphaticus, it is possible to recognize the pronounced forms during life, and to a considerable degree to avoid its special dangers. I believe that it is of considerable importance that the attention of military medical men, beginning with medical exemption boards, be sharply drawn to the stigmata of status lymphaticus, both for the purpose of establishing rules of procedure in the disposition of such cases, and in order to gather new information regarding the significance of status lymphaticus from the military standpoint, and also in order that the military physician may enjoy the intellectual satisfaction of understanding certain events occurring in the course of disease and injury that are generally quite obscure.

ANATOMIC CHARACTERS

Status lymphaticus is characterized by a feminine type of bodily conformation in the male, absence of axillary and deficiency of pubic hair, general delicacy of integument, a tendency toward abundant deposits of subcutaneous fat, evidence of rickets, small size of the heart and thinness of aorta and other arteries, persistence of thymus, and hyperplasia of lymphatic tissues in tonsillar ring, ileum and spleen.

Two phases of these physical characters are recognized, in children and in adults, the latter being a recessive stage of the former. In infants and before puberty, lymphatic hyperplasia, large thymus, and signs of rickets are prominent, while in adults the lymphatic hyperplasia is gradually succeeded by atrophy and by a form of sclerosis which Bartels[1] says is peculiar. In adults the unfolding of the growth tendencies of the body brings out the feminine characters of the male physique, and often the persistence of the thymus, while necropsy discloses hypoplasia of the heart and the arterial system.

The scope of the anatomic changes included by many observers in status lymphaticus is considerable. The body is gracefully formed, the limbs rounded, the thorax long, the pelvis heterosexual. Pribram[2] includes genu valgum, persistence of epiphyseal lines, flatfoot, and hyperextensibility of the elbow joints. He found that the outstretched arms exceed the body length in 95 per cent. of the cases, but this relation often occurs without status lymphaticus.

The genitals are hypoplastic (46 per cent.), and cryptorchidism may occur (from 2 to 3 per cent.). Kyrle[3] observed that the testes were usually normal in the gross, but presented well marked interstitial orchitis, without much disturbance of spermatogenesis or alteration of interstitial cells. In certain cases the testes are atrophic. In fifty-five cases Herrmann[4] found the ovaries usually enlarged and much elongated from interstitial fibrosis. Axillary and thoracic hair is scanty or absent, and the pubic hair in the male ends in a horizontal line, as in the female (96 per cent.). The beard is scanty (57 per cent.), and sternal hair absent (90 per cent.). The hair of the limbs is scanty or absent (65 per cent.).

The skin is delicate. There is a tendency toward abundance of subcutaneous fat, and some subjects are distinctly obese. In certain cases with distinctly atrophic genitals, status lymphaticus is associated with eunuchoidism. In the obese eunuchoids described by Tandler and Gross,[5] persistence of the thymus was believed to exist because of roentgen shadow, but the exact relations of eunuchoidism to status lymphaticus remain to be determined. Very pronounced feminine characteristics belong chiefly to the former condition.

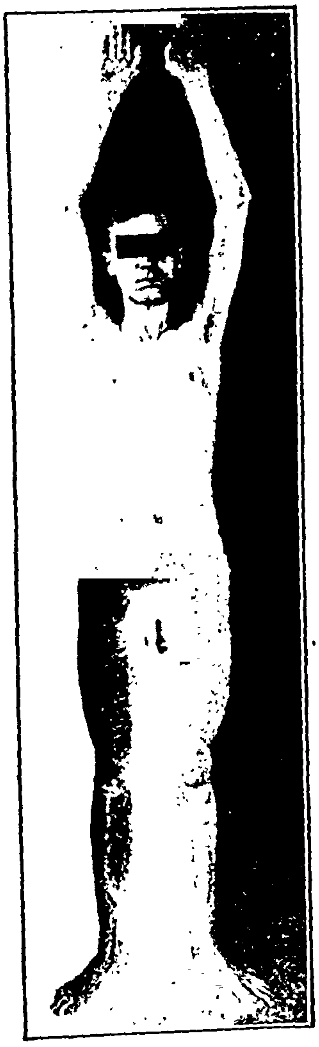

Fig. 1.—Partially developed status lymphaticus in man, aged 21. Patient has shaved only twice. Pubic hair of feminine type. Long, slender thorax.

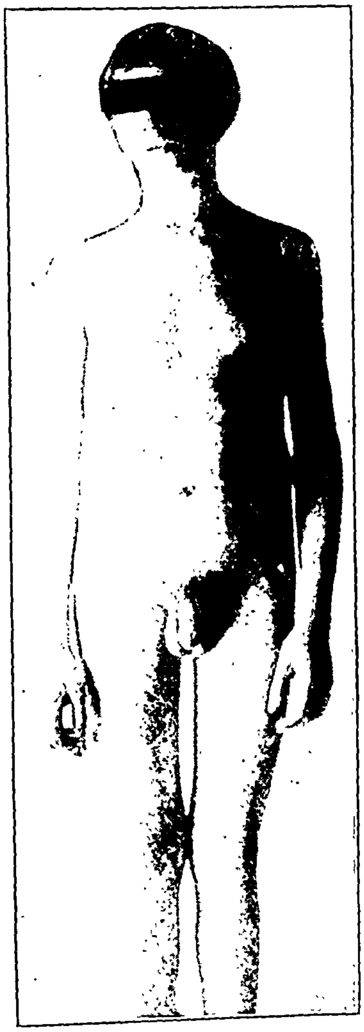

Fig. 2.—Status lymphaticus of feminine type; genitals apparently normal. Photograph lent by Dr. Charles Norris.

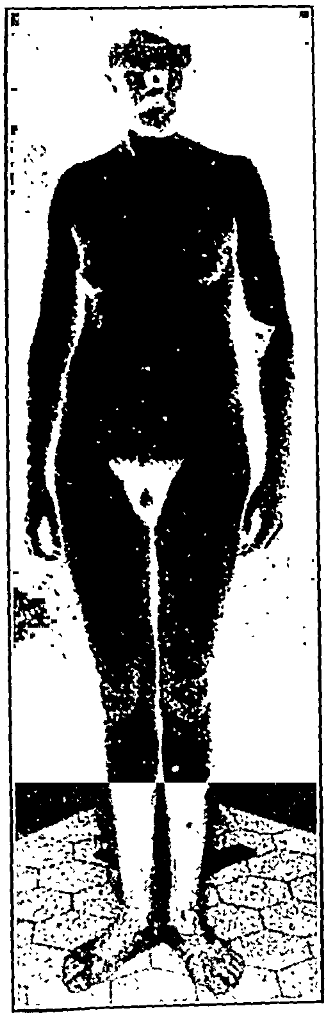

Fig. 3.—Eunuchoidism, a condition probably involving status lymphaticus, in man, aged 22; feminine body; hypoplasia of genitals. (After Saenger.)

In the female the external signs of status lymphaticus may be limited to thinness and delicacy of skin, narrow waist, arched thighs, and scanty hair. Menstruation is usually delayed, the uterus may be infantile, and the breasts poorly developed.

In children the thymus enlargement may be the most prominent feature, and thymic pressure has probably been one of the chief factors leading to the death of infant subjects of status lymphaticus. This organ persists in many young and some older adults, as one of the most significant signs of status lymphaticus. It shows simple lymphoid hyperplasia, and the process may affect aberrant lobes in the neck or in the thyroid gland. Through its relation to the thyroid it is believed to figure prominently in the cases of status lymphaticus with thyroid manifestations. In most adult subjects the thymus is small or atrophic.

The lymphatic hyperplasia occurs in infants and children up to and sometimes beyond puberty, and is often a most distinctive feature, differing from any other known form of lymphatic overgrowth. The pharyngeal ring of lymph follicles is enlarged (80 per cent.), the lingual follicles being affected more than the faucial tonsils. Rarely the cervical nodes are slightly swollen. Very striking overgrowth of Peyer's patches, especially the lowest, is frequently observed. The splenic follicles are enlarged and plainly visible to the naked eye. Swelling of mesenteric nodes is occasionally seen. The structural changes consist in overgrowth of lymph follicles and lymphocytes. Symmers[6] emphasizes the presence in many cases of degenerative and even necrotic changes in the centers of follicles, and of sclerosis which follows these changes.

Hypoplasia of the heart and aorta is the most prominent of the conditions found at necropsy. There are no systematic data regarding the weight of the heart in status lymphaticus, but the organ is usually distinctly undersized. The aorta is thin and delicate, often to a striking degree. Delicacy of the entire arterial system may exist and form the basis of apoplexy in young adults, and of various functional disorders. Some observers have attributed to the overstraining of a small heart certain forms of interstitial myocarditis occurring with status lymphaticus. With the hypoplasia of heart and aorta Virchow associated chlorosis, which may occur in subjects of status lymphaticus.

Many other abnormalities in the construction of organs are occasionally seen, as lobulated kidneys, hypospadias, polymastia, abnormal fissures, and congenital angiomas, but they are not sufficiently frequent to be regarded as essential. They seem to support the view that some fundamental defect of development exists in these subjects.

OCCURRENCE

Since there are all grades of status lymphaticus, its frequency will depend somewhat on the attitude of the observer. Two statistical studies are available.

Emerson[7] analyzed his own and Norris' observations at Bellevue Hospital. Among 3,600 necropsies, 288 (8 per cent.) showed status lymphaticus, 70.2 per cent.

active and 29.8 per cent. recessive; 9 per cent. failed to show any other cause of death, and 242 died of infectious diseases. Recently Symmers has collected the Bellevue Hospital material, finding 457 cases of status lymphaticus among 5,652 necropsies. Of these, 249 were analyzed, showing that 118 were active, 89 recessive and 42 partial or intermediate. It was most frequent between 20 and 40 years. Pribram observed several of the clinical signs of status lymphaticus in 150 among 2,500 patients at von Jaksch's clinic (6 per cent.).

Municipal hospitals, gathering a large number of sudden deaths, show a relatively high proportion. It is obvious that the condition must appear highly important to medicolegal observers, while for the same reasons the general practitioner commonly ignores it, or more often has never had it brought to his attention.

Woodward seems to have suspected that small hearts were connected with sudden deaths. He referred to sudden deaths of convalescents from dysentery, often while the patients were walking about, and in ten of these the heart was noted as small, in four cases weighing 5½ ounces or less. No cause of death was discovered. Among the general cases of undetermined causes of death, twenty showed small hearts, in eight of which the weight fell below 6½ ounces, once to 4 ounces.[8] I am unable to find any other reference to this condition in reports from the Civil War.

CLINICAL MANIFESTATIONS

Only a brief enumeration of the clinical conditions in which status lymphaticus figures can be attempted within the scope of the present report.

In infants, many cases of unexpected death, occurring instantly, or after rapidly increasing dyspnea or heart failure, have revealed only an enlarged thymus which has mechanically obstructed breathing and heart action. This so-called thymic death is one of the most numerous and best known groups of cases.

Death under anesthesia occurs, in a large proportion of cases, in subjects of well-marked status lymphaticus. Here respiratory failure precedes stoppage of the heart.

Cardiac and arterial hypoplasia dominates the clinical picture in most adult cases. The small heart, even under the most critical estimate, must reasonably be assumed to carry with it defective muscular energy and low metabolism. The subjects tire easily and suffer from palpitation, pain, cardiac dyspnea and low blood pressure, and in many cases of sudden death it has been assumed that the heart stopped beating from exhaustion or from some form of reflex inhibition. Here may be classed the numerous cases of sudden death while bathing, or after trivial mechanical trauma. Many have warned against the careless injection of alien proteins, antiserums, vaccines and arsphenamin in subjects of status lymphaticus. While in this field of functional disturbance of the hypoplastic heart the evidence is vague and inconclusive, it may at least be said that these cases are wholly without other explanation, and invite investigation by modern methods. Ortner[9] was quite sure that the small heart is particularly subject to functional disorders and subsequent myocardial changes.

Precocious apoplexy in young adults is a highly characteristic termination of status lymphaticus, is comparatively frequent, and may be expected especially in military service. Norris encountered many such cases at Bellevue Hospital. I have examined several of them collected by my colleague, Schultze, in which the cerebral vessels were extremely delicate and usually free from sclerosis. They are clearly distinguished from nephritic cases in young adults, but nephritis may be added.

In relation to infectious diseases, status lymphaticus appears to have much significance. It has long been known that these subjects do badly under infection. Elser and Huntoon[10] found that in all their fulminant cases of meningitis the patients were subjects of status lymphaticus, and this observation has been supported by others. McNeil[11] reports fulminant pneumonia with status lymphaticus. Symmers reports fifty-five necropsies on meningitis, 60 per cent. in subjects of status lymphaticus. In thirty of these cases of known duration the disease was fatal in an average period of 3.4 days, and nine patients died within forty-eight hours. In thirteen subjects of status lymphaticus dying from typhoid fever, the average duration was fourteen days. In his series, about 10 per cent. of all subjects of status lymphaticus presented acute infective lesions of the heart valves. Daut[12] found that more than 25 per cent. of patients dying of diphtheria were subjects of status lymphaticus.

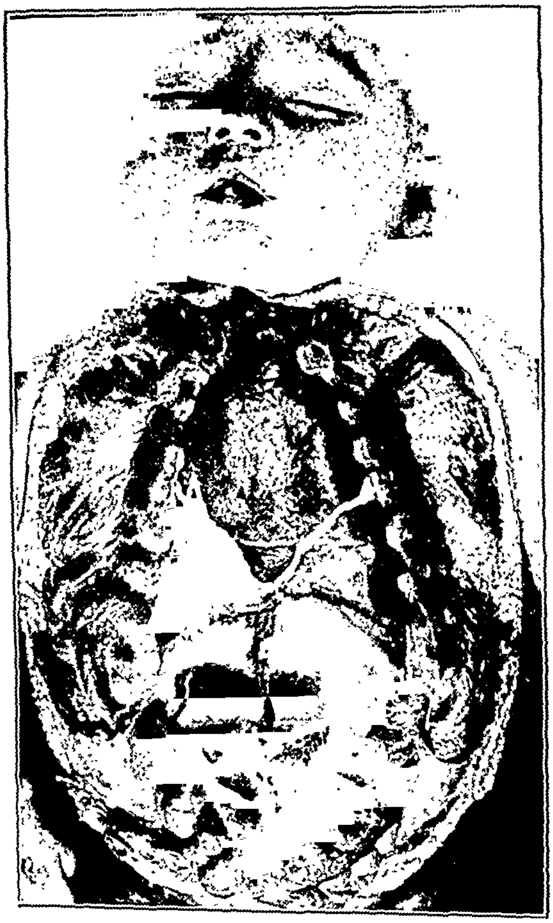

Fig. 4.—Hypertrophic thymus in a new-born infant; case of Dr. Symmers'.

The relation to tuberculosis shows several phases. The combination of rickets, lymphatism and scrofula in children is emphasized by Bartels. Subjects of status lymphaticus in general show a high resistance to tuberculosis, which takes the form of caseous lymphatic lesions, solitary brain tubercle, atypical bone lesions, etc. Addison's disease nearly always occurs in subjects of status lymphaticus (Bartels).

In exophthalmic goiter, thymic enlargement is very common, and practically all fatal cases show pronounced hyperplasia of the thymus and often other signs of status lymphaticus. The high mortality of operations on the thyroid may thus receive a partial explanation. Simple goiter is relatively common in status lymphaticus.

The condition in status lymphaticus appears to be identical with none of the specific disorders of the endocrine system, but there are definite indications that these glands are involved in various ways. The bodily configuration has some of the features of adiposogenital dystrophy. Many of the cases of hypophysial dystrophy of Froelich's type are associated with other and pronounced signs of status lymphaticus.[13] Hypoplasia of the genitals is a common feature in both sexes. The hyperplasia of the thymus can hardly be without some bearing on the question of its supposed internal secretion. Hypoplasia of the suprarenals is repeatedly observed. In this territory may possibly be found the key to the complete solution of the complex situation in status lymphaticus.

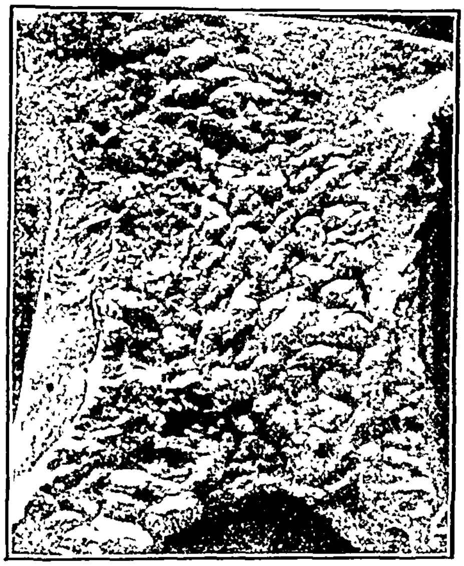

Fig. 5.—Hyperplasia of lowest Peyer's patch in status lymphaticus. From the author's case of chloroform death (1897).

The nervous system is essentially concerned in status lymphaticus, but little is known of the nature of its relation. Rokitansky spoke of overdevelopment of the brain in early life in these subjects, and Bartels has noted multiple foci of gliosis with a tendency to glioma. No definite anatomic changes in the brain have been established in status lymphaticus, but the clinical data are in some respects quite impressive. Ohlmacher[14] found that the great majority of fatal cases of epilepsy are subjects of status lymphaticus. The condition is relatively common in the mentally deficient. Not a few cases escape all other hazards, only to end in suicide. Bartels, from a study of 122 cases, concluded that status lymphaticus is practically constant and often pronounced in subjects of suicide. Miloslavic[15] studied 110 cases of suicide in military service, finding 80 per cent. with signs of status lymphaticus, as follows: thymolymphatic, 47 per cent.; lymphatic, 21 per cent.; thymic, 8.5 per cent.; partial, 3.5 per cent.

Symmers found pronounced hypoplasia of heart and aorta in all of five cases of caisson disease. This observation falls in line with others which indicate that the entire cerebral vascular system in these subjects is defective. It may be of importance in aviation.

PATHOGENESIS

The central factors in the origin of status lymphaticus must be found in the congenital hypoplasia of the cardiovascular system, and in hyperplasia of the thymus. Nothing is known of any hereditary element. The small heart and the blood vessels do not grow up with the body, but remain delicate and inadequate. Yet the skeleton, muscular system and organs are often highly developed in these subjects. In some respects this maladjustment may be brought into relation with a persistent and overactive thymus. Gudernatsch has shown that thymus feeding of tadpoles causes overgrowth of the body without corresponding maturation, which may be accelerated by addition of thyroid substance to the diet. Genital hypoplasia, although present in some cases, is not constant or as a rule prominent, but may be connected with a persistent thymus. Henderson[16] and Hatai have shown that the thymus tends to persist in castrated animals.

In subjects of this anatomic constitution there is evidence that external factors play a part in developing the lymphoid hyperplasia. Cameron,[17] who finds that more than 40 per cent. of the children coming to necropsy at Guy's Hospital are subjects of status lymphaticus, attributes the lymphatic hyperplasia to chronic inflammation of the various mucous membranes. He designates early status lymphaticus as status catarrhalis, or the exudative diathesis, finds the cause in poor hygiene and excessive carbohydrate feeding which favors wateriness of the tissues and rickets, and urges the remedy of correct feeding. His views deserve careful attention, but do not remove the necessity of a congenital basis of the condition. Blumer,[18] and especially Symmers, impressed by the presence of irritative hyperplasia of the lymph follicles with degeneration and necrosis, develop the idea of autointoxication, and Symmers thinks the intoxication of anaphylactic type, the system becoming sensitized by repeated discharges of lymphocytic proteins. The adjustment of this line of speculation with established principles of immunology is not entirely clear.

The question whether the enlarged thymus mechanically compresses the trachea in infants seems still undecided. That there is a reflex mechanism which stops the heart under conditions of mild nervous shock seems highly probable. Many clinical observations show that the vasomotor system of these subjects is quite unstable and very sensitive. Laryngismus is common in the children, and many fatalities are preceded by convulsions.

CLINICAL DIAGNOSIS

Well-marked cases of status lymphaticus are easily recognized by inspection of the whole body. An enlarged thymus in children or young adults may be recognized by the roentgen ray, but it is improbable that the lesser size of the simple persistent thymus can be determined by any method. The pharyngeal ring of lymph nodes is too often swollen in other conditions to serve as more than a suspicious sign. The lymphocytosis commonly present is too indefinite to be of any positive diagnostic value. I know of no observations by the roentgen ray on the appearance of the hypoplastic heart and aorta, nor of studies on the blood pressure.

The lesser grades and partial forms of status lymphaticus must probably be marked as unsafe territory, especially for the military physician. Nevertheless, when several of these less definite signs can be demonstrated in subjects of slightly developed bodily characteristics, a probable diagnosis of status lymphaticus may often be established with reasonable certainty. None of these limitations apply to the recognition of status lymphaticus at the necropsy, by the systematic examination of all the organs, followed by microscopic control.

On the other hand, the suspicion of status lymphaticus should be entertained by the military clinician, not only in the obvious cases, but in dealing with any of the manifestations mentioned above, such as irritable heart, thyroidism, nervous breakdown, epilepsy, shell shock and fulminant infectious diseases, and this suspicion should be followed to the necropsy table.

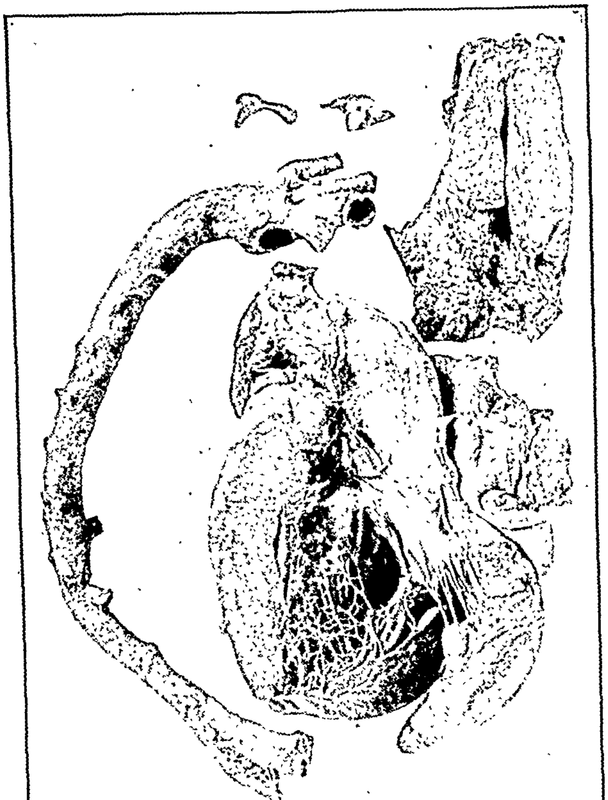

Fig. 6.—Hypoplasia of aorta and suprarenals, and hyperplasia of thymus in a girl, aged 20 years, dying of cerebral hemorrhage. Weight of heart, 307 gm.; thymus, 41 gm.; suprarenals, 10 gm. Aorta, widest external circumference, 5 cm. A case of Dr. Otto Schultze's.

With these well-attested evidences that status lymphaticus carries with it a defective vitality that results in sudden and unexpected death in many conditions of trauma and disease, it is obvious that this dyscrasia must be of considerable importance in military medicine. It would seem desirable that intelligent efforts should be made to detect the condition whenever present, that definite procedures should be adopted when it is found, and that systematic study of the material collected by the Army medical forces should be undertaken in order to elucidate many problems that still remain unsolved regarding its origin, nature and significance:

1. In the physical examination of drafted men a pronounced grade of status lymphaticus ought to be recognized at a glance, and it would seem reasonable that the subject should be rejected as unfit for active military service. Whether it is practically or economically wise to accept such subjects for any form of military service can be determined only by systematic clinical observation of those already in the service. Such a study would occupy years, and ought to be undertaken under the favorable circumstances that exist in the Army and cannot be duplicated elsewhere.

2. In the subsequent examination of men already in the service, the presence of status lymphaticus should be noted, and these men should be assigned to the less hazardous occupations.

3. In the present state of knowledge, the most substantial evidence regarding status lymphaticus and the chief source of material for study that may elucidate its problems must still be obtained from postmortem examinations. The presence of status lymphaticus should be looked for in every postmortem examination, and affirmed or negated in every protocol. The anatomic evidence of the condition should regularly be preserved for further study, and the effort be made to discover any further extensions of the anatomic changes that may possibly occur in the condition.

At present the indications point to the glands of internal secretion as most likely to throw new light on the nature of the condition. In this field histologic studies are required on the thymus, thyroid, hypophysis, pineal gland, carotid gland, pancreas, suprarenal, testis and sympathetic system. Any undertaking of this sort to be adequate can hardly omit attention to any organ in the body. The bones should be examined for old rickets, and the bone marrow for evidences of hematopoietic disorder. Since the circulatory system long retains the impress of status lymphaticus and is a specially important factor in the adult, observations on the heart, its musculature and nervous apparatus, and on the aorta and arteries are called for.

4. The clinician has an interesting task and a complex function to perform in connection with the study of status lymphaticus and in the employment of the doctrines that have accumulated about it.

The final test of the existence and importance of a bodily constitution of defective general vitality must be clinical. Since the majority of patients survive to middle life, most of them come repeatedly under clinical observation. Since there must be all grades of status lymphaticus, the condition often merges with that known as the idiosyncrasy of the patient, recognition of and respect for which constitute a substantial part of the art of medicine. In general, the clinician must determine how these subjects react to injury and disease.

Very numerous situations previously stated, showing that many patients react with sudden death, quite sufficiently impress the general clinical importance of status lymphaticus. Of the manifestations of the lesser grades of the condition little is known, and here the need of keen observation and sound clinical judgment is apparent. It would seem easy either to exaggerate or to undervalue the clinical importance of status lymphaticus. It seems not improbable that some of the best of the world's work has been done by subjects of status lymphaticus, but in the military field that work must have been fortunately adapted to the physical defects of the worker. Therefore, it seems not necessary for the clinician to condemn every subject showing status lymphaticus, but rather to find the subject's proper place in the military organization.

Speculation which seems legitimate suggests several topics of research that may be profitable from the clinical side.

No surgeon can afford to ignore the importance of status lymphaticus in the choice and administration of anesthetics.

The employment of injections of alien proteins and of arsphenamin should be undertaken with caution in subjects of status lymphaticus.

Further observations on the course of infectious diseases in subjects of status lymphaticus are called for. The idea that a fulminant course of meningitis or pneumonia is largely determined by status lymphaticus challenges the present conceptions of most clinicians and bacteriologists, but cannot be contested except by carefully accumulated clinical data.

The resistance to tuberculosis claimed by Bartels for subjects of status lymphaticus may be determined by the clinician and the pathologist. Not many clinicians will be prepared to accept the statement that Addison's disease occurs almost exclusively in subjects of status lymphaticus, but this question can be determined by the material collected in the Army.

Those who are interested in the doctrines of internal secretions may find profit in pursuing the relations of status lymphaticus to the ductless glands.

The neurologist meets phases of status lymphaticus notably in suicide, epilepsy and possibly in certain forms of mental disturbance. It would be interesting to know if any considerable proportion of patients with shell shock or other forms of nervous breakdown, with or without anatomic lesions, belong in the category of status lymphaticus. Given an overdelicate cerebral vascular system, one has an obvious predisposing condition to miliary or microscopic hemorrhages, such as occur in concussion and carbon monoxid poisoning. Almost the entire anatomic picture of status lymphaticus lends itself readily to the explanation of physical and mental breakdown on the battle field.

The irritable heart presents itself as a possible phase of the defective circulatory apparatus of status lymphaticus and one in which clinical observations on a large scale could be carried on.

All of these suggestions, however, must be offered with the greatest caution. Otherwise status lymphaticus may be lost in a maze of minor and ill defined clinical disorders of very doubtful relation to the very substantial anatomic alterations that appear in the bodies of pronounced cases. Such a fate seems to have overtaken neurofibromatosis at the hands of several continental writers, who have attempted to attach to this extremely specific anatomic condition all manner of disorders of the skin and nervous system.

The present conditions in the military service in America, when numerous races and classes are brought under the draft, seem to offer quite unique opportunity of determining the economic and military importance of definite status lymphaticus, and it is to this aspect of the subject, rather than to its possible ramifications, that the present note is directed.

Army Medical Museum.

SUPPURATIVE GINGIVITIS WITH ALVEOLAR INVOLVEMENT

A NEW SURGICAL PROCEDURE *

ARTHUR ZENTLER, D.D.S.
Associate in Oral Surgery, New York Post-Graduate Medical School and Hospital; Surgeon, Department of Oral Surgery, New York Throat, Nose and Lung Hospital (Columbia University, Advanced Courses for Practitioners)
NEW YORK

It is my intention to deal with that phase of the disease commonly known under the confusing name of pyorrhea alveolaris, which as indicated by its histopathology is a purely surgical disease and must, therefore, be treated surgically, this alone promising an expedient and a permanent cure.

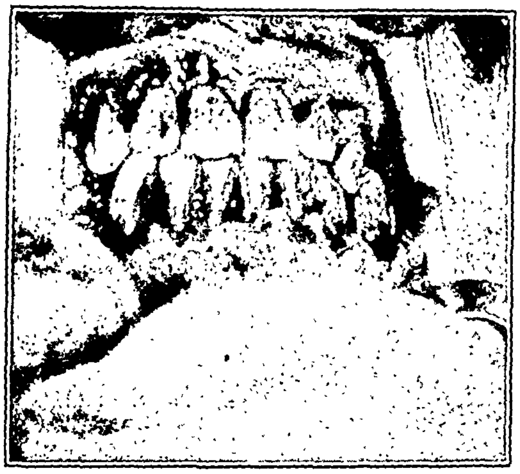

Fig. 1.—Appearance before operation.

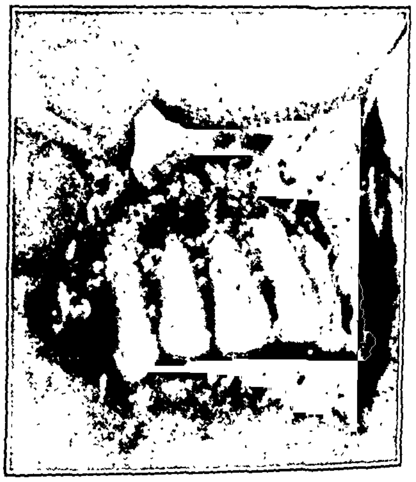

Fig. 2.—Flap lifted and retracted.

For the purpose of clear presentation, I shall briefly state that I prefer to call the diseases involving the gingivae and their soft and hard underlying and adjacent tissues by the generic name given them by Talbot, of gingivitis. Further, that for purposes of practical study, I classify gingivitis into superficial, hemorrhagic and suppurative.

The first class of the disease and the less advanced forms of the second and third classes are ordinarily amenable to proper dental treatment (scaling, polishing, etc.) in conjunction with correction of such local and constitutional disturbances as may be present.

The more advanced hemorrhagic cases, and especially the advanced suppurative cases, accompanied by degenerative processes of the alveolar bone and the soft tissues immediately covering it, are usually either traumatic, being due to long neglected accumulations of salivary calculi or other irritants (ill fitting fillings, inlays, crowns, bridges, etc.), or they are a manifestation of a disturbed metabolism due to such diseases as diabetes, syphilis, tuberculosis or chronic or acute

---

* Read before the Section on Stomatology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

metallic toxemias, when serumal calculi may or may not be found on the roots of the teeth, and, if present, will act as an additional irritant. Whether of traumatic origin or of metabolic or of both origins, these forms of gingivitis are oral foci of infection, to which other systemic disturbances are attributed; but this phase of the subject is not to be considered here, except for the purpose of stating that it is a sine qua non that the treatment of the oral condition must go hand in hand with the treatment of the general physical condition; neither can be brought to a successful issue without a rational treatment of both.

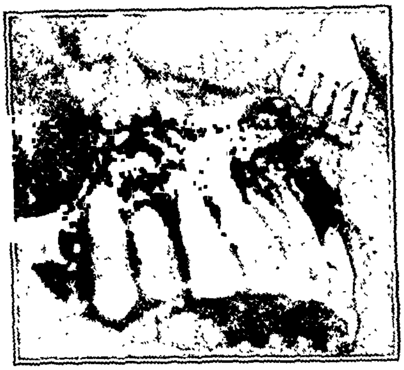

Fig. 3.—Appearance after removing all soft and hard diseased tissue.

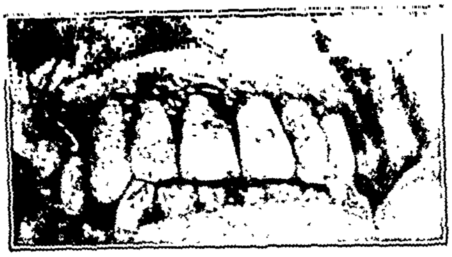

Fig. 4.—Flap replaced and sutured.

A typical report[1] of microscopic examination of specimens of tissues obtained from areas operated on reads as follows:

> The exposed connective tissue is of sluggish granulation type, heavily infiltrated by some polynuclear and many round and plasma cells. These last cells are so dense that the stroma is obscured throughout its length inward from the epithelium. The epithelium is not remarkable except at points where it is necrotic and desquamating. There are many congested capillaries and considerable extravasation by red blood cells throughout, and several spicules of alveolar bone are seen.

This shows that the condition present is of such character as clearly to indicate that nothing short of radical removal of all the involved soft and hard structures, going well into healthy surroundings, will render the part receptive of regenerative processes and insure an ultimate permanent cure. It is clear that an essential factor in operating on any part is that its approach be unobstructed, so that before terminating the operation, the surgeon may be certain of having actually removed all that is diseased; it is seldom, if ever, when this is not accomplished, that recurrence does not take place. This probably explains the reasons why, in advanced cases of so-called pyorrhea, very few permanent cures are effected with the treatments as generally practiced at present.

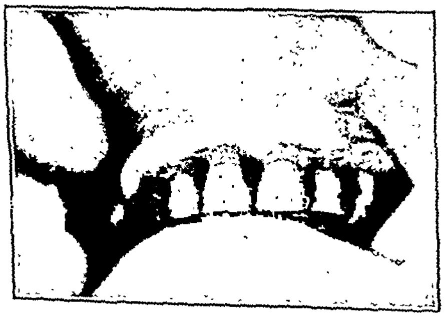

Fig. 5.—Typical appearance of upper anterior region before operation in an extensive case of suppurative gingivitis, in a patient aged 55.

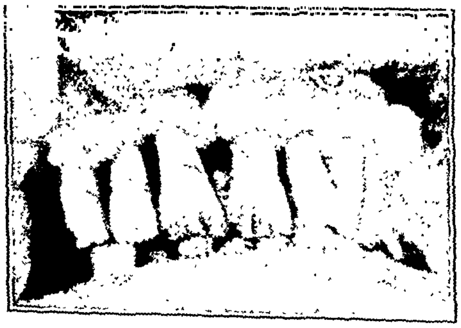

Fig. 6.—Same patient as is shown in Figure 5, six months after operation.

G. V. Black[2] speaks of the surgical treatment of pockets, describing a method of eradicating the pocket by "cutting away as far, or a little beyond, the point to which the disease has reached, which generally means some cutting away of the margin of the alveolar process as well as the soft tissue." He speaks of there being "considerable variation in results following this treatment. The rule is, however, that something will be gained in reducing the depth of the pocket each time the overlying tissue is cut away."

From this it is seen that while the need of radically dealing by surgical methods with these cases was recognized by Black, the result was not always a success and recurrence took place; hence the need of repeated ("each time") cutting away of the pocket.

Riggs, and others since his time, operated somewhat in the way described by Black. Robitzeck of Vienna, as long ago as 1862, devised an operation for cases involving an area over several teeth, sometimes all the anterior region or the posterior region or even both regions, consisting in excising with a straight incision through the soft tissues down to the alveolar process, all the abnormally appearing gum tissue. A scraping of the exposed alveolar bone followed the excision of the soft tissue, and the patient was dismissed. In cases in which cures were effected with this treatment, the result of the straight incision was such as to leave a very unsightly aspect of the parts.

After practicing Robitzeck's operation for a number of years, I have found that it was very useful in cases of advanced hemorrhagic gingivitis and often in cases of not very advanced suppurative gingivitis. I found, however, that in somewhat modifying his technic I could obtain a more pleasing ultimate appearance and a local condition more easily kept clean.

My modification consisted in excising the diseased gum tissue, instead of by a straight incision, by following the original festoons of the gums, going well into the healthy tissue, thus leaving behind a scalloped edge, which I packed tight with a strip of folded iodoform gauze one-eighth inch wide. The ulterior healing would result in an appearance of the gum very much as if it had never been diseased, and with no signs of an operation noticeable; the gingival papillae would be practically restored.

This operation, however, was purposeless in advanced suppurative cases in which the involvement of the soft and alveolar tissue was extensive, and recognizing the cause of the failure to be the lack of proper approach to all the involved area, I devised the following operation:

TECHNIC OF OPERATION

The patient is prepared as for all oral surgical operations, performed under procain-epinephrin conductive anesthesia.

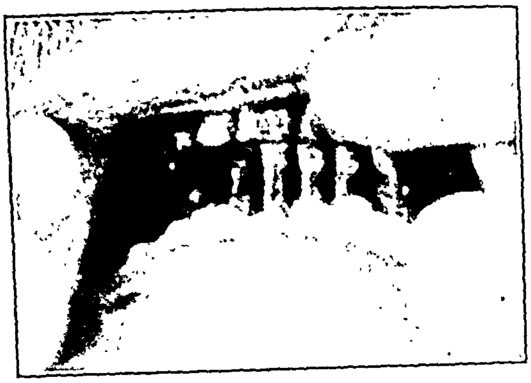

Fig. 7.—Typical appearance of lower anterior region before operation in an extensive case of suppurative gingivitis in a patient aged 55.

The part to be operated on (Fig. 1) is swabbed with tincture of iodin, and a flap is lifted by making two parallel incisions, starting at the cervical free border of the gum, and carrying them apically to the apical region each side of the area over the tooth or teeth involved. The incisions are made so as to penetrate the mucosa and submucosa, and to include the periosteum. This, with the gum tissue overlying it, is lifted with the raspatory, retracted, and held in position by the assistant (Fig. 2). Thus the diseased part is well exposed, and with suitable curets and knives, all the inflamed, infected, granulomatous tissue found, between and surrounding the roots of the teeth, is removed.

Next, with delicate chisels and mallet, the alveolar plate is chiseled away from around the denuded portions of the roots, so as to insure the removal of any and all infected bone covering the roots, which are then well curetted. The rough edges of the remaining alveolar bone covering the roots are well smoothed so as to form an even surface with them (Fig. 3).

The flap is then released, and its inner aspect is inspected for possible adhering inflammatory and granulomatous

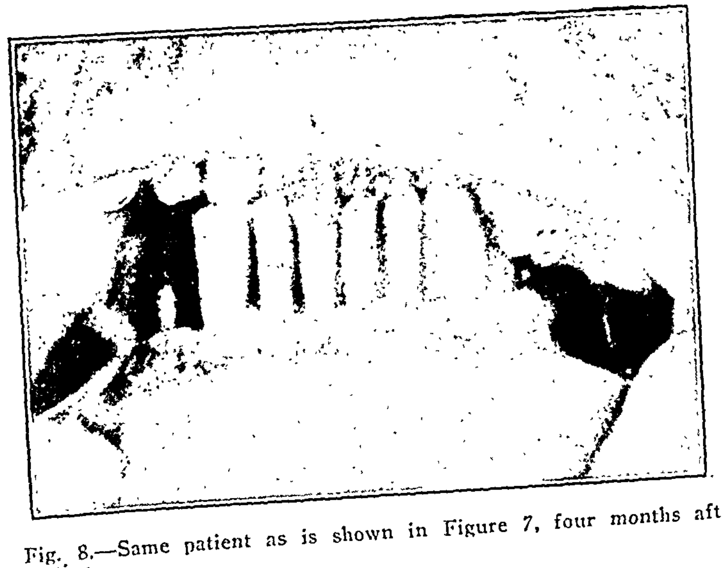

Fig. 8.—Same patient as is shown in Figure 7, four months after operation.

tissue, which is thoroughly curetted away, disturbance of the remaining healthy periosteum being carefully avoided. The parts are washed with physiologic sodium chlorid solution, swabbed with a 50 per cent. solution of the official tincture of iodin, the wound surfaces are freshened up, and the flap is replaced in position and sutured (Fig. 4).

The sutures are taken at each end of the incision, one near the cervical end and the other near the apical end. When the operation is performed over an area covering more than four teeth, it is well to take one or two additional sutures between the teeth, securing the approximation, for instance, of a labial flap to the palatal gingiva. The parts of the free edge of the sutured flap that appear to be necrotic from lack of nutrition, because of the long existing interposed infection, are cut away with sharp scissors, leaving a clean cut which, when healed, presents a well adhering surface, surrounding the root of the tooth. Before the patient is dismissed, the parts are again swabbed with tincture of iodin and covered with a strip of iodoform gauze, which is changed once or twice at intervals of twenty-four hours. The sutures are removed on the fourth or fifth day, and unless the operation was attempted in an extensively necrotic case, in which removal of the tooth or teeth should have been practiced, there will in time be new bone formation around the roots, complete reattachment of the soft tissues, and quite loose teeth will become firm and stay firm (Figs. 5, 6, 7 and 8).

COMMENT

It is needless for me to say that it is advisable that the mouth be placed in as hygienic a condition as possible before the operation, all exgingival irritants, such as salivary calculi or ill fitting fillings, inlays, crowns, etc., being removed from the area to be operated on, and preferably from the entire mouth. In cases in which, for some reason or other, this was not done prior to operation, the patient must be warned

Fig. 9.—Amount of alveolar resorption over upper anterior region in patient on whom operation was performed, shown in Figure 5.

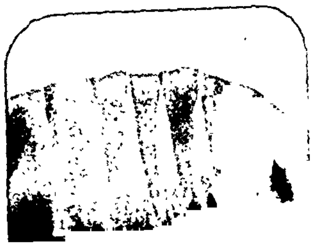

Fig. 10.—Amount of alveolar resorption over lower anterior region in patient on whom operation was performed, shown in Figure 7.

that it ought to be done as soon as the parts have sufficiently recuperated to permit handling them, and the rest of the mouth, for such purposes. This is usually from ten to twelve days after the operation. The patient may then resume the rational care of teeth and gums with tooth-brush and tooth-powder, etc., on the operated area. In the rest of the mouth this need not be interrupted at all, except in rare cases, for one day after operation.

There is usually no discomfort following the operation. At times there is some swelling and pain, after the effect of the procain wears off. The application of an icebag fifteen minutes to the hour, for two or three hours, usually brings prompt relief from pain and reduces the swelling.

All areas of the mouth, without exception, can be operated on as described above. I have extended the operation over as many as six adjoining teeth; but it is advisable when there is a great deal of suppuration in the entire region not to operate at one time over more than three or four teeth, in order to avoid opening up too large an area for septic absorption.

Whenever there are devitalized teeth in the area to be operated on, these must first be thoroughly treated; root canals must be thoroughly, aseptically filled. Apicoectomies may be performed at the same time as the operation for the suppurative peridental condition. In multirooted teeth this is not always practicable and, therefore, such nonvital teeth, with periapical and peridental pathologic conditions, would better be removed.

As in all other oral surgical operations, the roentgenogram (Figs. 9 and 10) is an indispensable adjunct in diagnosis. It is my experience that when the roentgenogram shows that one side of the root is still supported by investment tissue, the case is a good operative risk. Even in cases in which apparently, from the roentgenogram, the investment tissue is lost almost to around the apical region, the tooth, however, responding to the ethyl chlorid thermal test, the operation was successfully performed in a small number of cases attempted for purposes of experimentation.

ADVANTAGES OF THE METHOD

Full exposure of the entire affected area is obtained, and hence facility for a thorough operation. Once the operation has been correctly performed and the patient dismissed after a few days of observation, the parts formerly harboring infection are totally obliterated, and the patient is able with only reasonable care for cleanliness of the mouth to enjoy health in the parts formerly diseased. Some cases that would be pronounced incurable by the ordinary methods now in vogue for treating so-called pyorrhea alveolaris might be successfully treated by this surgical method.

8 West Fortieth Street.

ABSTRACT OF DISCUSSION

Dr. Arthur D. Black, Chicago: I approve of almost all Dr. Zentler presented, yet I cannot see the advantage of bringing back a flap and making a complicated operation instead of simply cutting away the overlying tissue. Scraping the surface of the root and bringing the soft tissue over it is just what we should not do. If the cementum is dead no soft tissue should be left overlying it. It is very easy to remove all of the detached tissue if the pockets are on the labial, buccal or lingual surfaces of roots, but when the pockets are between the teeth, it is necessary to cut away not only the tissue which is detached from the root, but also some of the soft tissue and the bone on the buccal and lingual sides of the interproximal space, in order to promote cleanliness. In most cases it is necessary to cut away a little of the edge of the bone, because the detachment from the root surface is usually deeper than the crest of the bone over the particular area. No matter what form of treatment has been employed, many operators have been deceived by the fact that the tooth, which may have been quite loose, has become much less so, and they have thought there has been a reattachment of the peridental membrane. The amount of destruction of the peridental membrane and the looseness of the tooth are not necessarily definitely related one to the other. Inflammations involving the peridental tissues cause the fibers to lose tone so they do not hold the tooth tightly in its socket. Following almost any treatment by which the inflammation is reduced, the teeth have less motion within a few days. This does not mean regeneration of tissue, but only that the fibers have regained their tone.

Dr. Moorehead might tell you of the experiments on dogs in which he and Dr. Noyes attempted to cut the peridental membrane away from the cementum. In each case they found, on microscopic examination, that the cementum had not been stripped; that a considerable amount of the soft tissue remained attached to the cementum. When cut in this way the peridental membrane will heal quite as readily as any other soft tissue.

Dr. George Edward Fell, Chicago: I have looked on this as a case of infection which must be overcome and in which the mouth has to be placed in such condition that reinfection cannot take place. It is evident that most of our cases of gingivitis can be cured if proper methods are employed and carried out radically.

Dr. Thomas L. Gilmer, Chicago: Dr. Zentler has indicated that bone is built up on the sides of the roots of these teeth. I would like to have him state rather definitely, if he will, what is the nature of the union between root and tooth. Is it vital, or if nonvital, is it a union similar to that found in implanted teeth; that is, an absorption of the cementum and a building in of the alveolar process?

Dr. Truman W. Brophy, Chicago: When a part is in an abnormal state, put it to rest. So that the very best thing to do in the treatment of a tooth that is inflamed, as described in this case, would be to put the parts to rest. Band the teeth and fix them so they will not be moving about after the operation is done. In the second place, the tooth root that has been deprived of its pericementum by this suppurative process should be opened and the diseased tissue, together with the end of the root, removed. A few days ago a dentist came with his patient, for whom he removed a first lower molar some weeks before. The patient was still in a great deal of pain and distress. He had removed the tooth, the roots of which had two great abscesses. The tooth came away, but the abscesses remained. After curetting the alveoli and removing the diseased tissue the man was very comfortable in a few days.

Precisely the same condition is present in these cases where it becomes necessary to penetrate the alveolar process and remove diseased tissue together with the end of the root. The surgeon would not be regarded as a very wise man or a very conservative practitioner if he would amputate a leg because his patient had an osteomyelitis. The position is exactly the same regarding the teeth. What the doctor showed us here in the excision of diseased teeth and removal of diseased teeth is correct, and by and by there will be sufficient enlightenment on this question so that so many teeth will not be extracted unwisely.

In regard to the entrance of germs after cutting off the root of the tooth and subsequent treatment, you do not try to sew up the socket or gum tissue after you extract teeth. You allow granulation tissue to fill the alveoli, and after a while you have a well-developed alveolar process. The same is true after excising diseased tissue and the end of the root. The cavity should be left precisely as a tooth socket is left following extraction of a tooth. We all know how these sockets have filled in, leaving a good, round, smooth surface. To amputate the apex of a tooth root is right, but to make a flap and close the cavity by stitches, leaving a place where another abscess may form, should not be done. I would make a funnel-shaped opening, remove the diseased root and diseased tissue, getting it free and clean, and then keep it open until granulations fill the cavity and until the healing is complete. In that way you will not have recurrence of the disease.

Dr. Frederick B. Moorehead, Chicago: The fundamental underlying question in the type of infection suggested by Dr. Zentler is with the hard tissue and not with the soft tissue. The seat of pathology in these cases is in the hard tissue. The most important question in this whole matter is that of a normal circulation. Where you find a proliferating endarteritis associated with a chronic heart or kidney no amount of local treatment will avail. These infections will not clean up in the absence of a healthy circulation, which, of course, cannot be had unless the blood vessels are normal. Any method, therefore, that has for its object the saving of teeth under these special conditions must be contingent on the general condition of the patient. One may undertake to save teeth when the general conditions are good, while he would remove similar teeth where general conditions were poor. The condition of the circulation and the general reparative power of the patient are paramount factors in guiding us between our efforts to save teeth and their immediate removal. The tooth has no analogue and one cannot, therefore, make a comparison between a tooth and other bony structures of the body. One half of a tooth root may be vital because of its investment in peridental membrane, while the other half may be a foreign body. The portion of the tooth root which has been deprived of its peridental membrane through infection will act as a foreign body and not be sequestrated. This is not true of any other bone infection in the body. For example, one half of a long bone may be devitalized through infection and be thrown off as a sequestrum. There can be no organic union between a tooth root which has lost its peridental membrane and the surrounding bone or soft tissue. It would seem, therefore, that these elemental fundamental facts must be our guide in undertaking the management of infected teeth.

Dr. E. S. Fuller, Dayton, Ohio: Some years ago, in order to obtain better access for cleaning the root surface of a lower incisor, I made an incision along the axial line of the tooth, cleaned the surface and sutured the gum flaps together. The sutures pulled out and the root surface became exposed. This I thought unfortunate at the time, but now I think it was the best thing which could have happened. During the past three years I have been treating these "pyorrhea pockets" by removing the overlying gum tissue in all cases, excepting those where the pockets were shallow enough to become obliterated by the reduction of the gingival inflammation following the removal of deposits and the cleaning of the root surface. Many cases are seen showing a deep "pyorrhea pocket" on both the mesial and distal proximal surfaces of a tooth—say a bicuspid, for example—the adjoining teeth not being affected. In these cases I frequently extract the diseased tooth rather than resect away the gum tissue from the interproximal space, as a horizontal resection would destroy the attachment of the tooth not involved.

Dr. Arthur Zentler, New York: To understand the character of the union obtained we would have to secure a section embracing all the tissues concerned and submit the whole for histologic examination. It is not easy to obtain human subjects for this. Animal experimentation may be used for the purpose. I believe, however, that we do not have the same conditions in animal as in human mouths. Practical examination shows a union, in operated cases, difficult to penetrate with fine probes. Only by exposing the entire involved area can one eradicate the disease. Simply cutting away the pocket has not proved permanent.

Where I operate at the same time for peridental and periapical infection, I make the incisions as described in my operation. A month after removing the sutures there is no sign left of these incisions, while with the semicircular incisions for apicoectomies cicatrices are present for a long time. One need not fear to suture the flap in either of these operations, provided the operation is done as aseptically as it should be done. I never had an ulterior infection due to suturing. I thought it understood that only healthy tissue is allowed to remain, and in speaking of reattachment I did not mean a reattachment of pericementum, but a reattachment of soft tissues that had been lifted and then replaced carefully, saving the healthy periosteum. Twice I operated in cases previously splinted. The operations were failures. It was due, I believe, to the lack of normal motion. It interferes with circulation and deprives the part of proper nutrition.

It is true that the fundamental pathology is with the hard tissues and not with the soft, and that is precisely why I felt the necessity of lifting a flap and of getting to the hard tissues underneath. That is why I chisel away a strip of the involved alveolar plate as well as curetting the soft involved tissue which lies over it and surrounds the roots. That is why I pronounced it a poor operative risk to operate when all investing tissue is gone, and advise in such cases removal of teeth.

As to the general condition of the patient, I think it is understood that if it cannot be controlled one need not attempt local treatment expecting success. Both must go hand in hand. The local circulation will be improved by the operation if we remove the infected parts. The general circulation must be taken care of by the patient's physician.

Dr. Brophy: Is there not some vitality left in the cementum?

Dr. Zentler: Wherever there is cementum left on a portion of the root that had prior to operating a detachment of the investing tissue, it is an open question in my mind whether this cementum is not able to throw off further cells into newly created healthy surroundings to form some sort of attachment. Where suppuration has intervened I do not believe there will be any live cementum. We get a reattachment of healthy tissue to healthy tissue in approximating them. You need not fear at all to remove some of the healthy tissue if you must do it in order to eradicate all the diseased tissue. The lost healthy tissue will be replaced the same as in any other surgical procedure.

POSSIBILITIES OF FRACTIONAL GASTRIC ANALYSIS *

MARTIN E. REHFUSS, M.D.
PHILADELPHIA

Fractional gastric analysis has for its purpose the determination of the evolution of gastric digestion. The necessity for such extended technic is justified by the fact that gastric digestion is marked by a series of constantly changing phases, so that it may now be definitely stated that an examination of any single phase of the digestive curve gives no information as to what has preceded or what will follow that phase. The most marked changes may occur in comparatively short intervals, so that findings at one period may be doubled or tripled at another period. The main point, however, is the essential fact that gastric digestion is the response of the organ to a definite stimulus, which, in health, evolves in a perfectly methodical and coordinated manner, and in disease evolves with every possible variation. In order, therefore, to interpret gastric disease, we must study the elements governing the response of the organ in health.

NORMAL DIGESTION

From a study of normal digestion with every form of foodstuff, which the entire staff of the chemical department of the Jefferson Medical College was engaged, we arrived at the following conclusions:

Human gastric digestion is divided into a series of recurring cycles which, for the want of better names, we have called the digestive and interdigestive cycles. These succeed each other in health with regularity and represent most perfectly the normal gastric mechanism. The digestive cycle is that portion in response to the ingestion of food of any kind and evolves in a perfectly coordinated manner. There is practically no latent period and there are well marked psychic and chemical phases to secretion. The psychic secretion is very considerable, as we have been able to show, and in health it probably averages 250 c.c., lasting from sixty to eighty minutes and being marked, according to our recent studies, by changes in environment, fatigue, etc. The total acidity averages 97.2 in our series and it is markedly reduced, but does not disappear with atropin administration. The chemical secretion probably commences early but reaches its height later and completes digestion. During this active period, we notice (1) the relaxation of the perisystole and the inauguration of peristalsis, and (2) a change from the resting secretion to a pronounced secretion of much higher acidity. Furthermore, we can detect certain regulating mechanisms such as tryptic or duodenal regurgitation regulating acidity. This cycle is constantly changing as each factor comes into play. It is followed by the interdigestive phase characteristic of normal digestion.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918

The stomach is never empty, and there is always physiologically active secretion, but the resting secretion or the residuum seen in the interdigestive phase is very different from the digestive secretion. The quantity averages 50 c.c., the total average acidity being only 30 and the free acid 18, while the presence of bile is much more constant (55 per cent); and tryptic regurgitation is almost constant. Instead of peristalsis, we have perisystole, tonal, and hunger contractions and a relaxed pylorus. It is the study of these phases so characteristic in health and altered by disease that yields us accurate information regarding gastric disease. All the motility changes only translate themselves by a diminution or increase in the interdigestive period.

We are now prepared to say that there is no one form of curve seen in health, but that the curve of the digestive period may be one of three kinds, depending on the type of individual, hypersecretory or hyposecretory. Further study of healthy persons only emphasizes the necessity for retaining these types. In a résumé of 842 complete curves on various foodstuffs with more than 20,000 titrations, we found that 383, or 45 per cent., exceeded 100 total acidity, and on that study embracing three years' work, we are prepared to state that no acid figures occurred in disease which could not be duplicated in health. In other words, we found that 45 per cent. of all responses in health showed so-called hyperacidity, while 42 per cent. of my ulcer series showed the same thing. In other words, there is no greater incidence of high acid figures in ulcer or in any other gastric disease than in health, a fact that raises the extremely important question as to whether an actual demonstrable hyperacidity ever does occur. We must face these facts squarely before we can make progress in this line. They are facts which may be verified and our ideas must be altered to meet them. Furthermore, we are prepared to state that hypersecretion in some form occurs in about 40 per cent of normal persons.

PATHOLOGIC VARIATIONS

In disease, every variation occurs from a total suppression of the gastric secretion to an exaggeration of all the phases. We might classify the elements into (1) those which are a modification of normal total acidity and free acid of the secretion, showing the presence of duodenal regurgitation, and (2) those which are frankly abnormal, such as blood, pus, mucus, certain organic acids, and pathogenic organisms constantly present. The study of normal digestion emphasizes one important point, namely, that at certain phases certain acidities and quantities of secretion are normal and at other phases these same figures are abnormal. For instance, instead of a coordinated curve after an Ewald meal with its height at the one hour and one and one-quarter hour point, we may have a total displacement of the curve, either a markedly exaggerated phase during the first hour or a slow initial phase, followed by pronounced findings at the end of the second hour. Study of pathologic curves shows that every variation of secretion may occur, instead of perfect evolution of digestion. There may be (1) a delay in digestion, (2) an acceleration in digestion, (3) a disturbance in secretory velocity resulting in hyposecretion or hypersecretion, and (4) alteration of digestion by the addition of frankly pathologic products, such as blood, pus and mucus.

We recognize that alterations may come through the systemic circulation (soluble toxins, bacteria) blood dyscrasias, resulting in altered mucosal conditions and altered secretory digestion, or through disturbances in the portal circulation (cirrhosis). These systemic conditions may stimulate or depress secretory activity. Again we know definitely that a lesion elsewhere in the gastro-intestinal tract (gallbladder, appendix) may increase the irritability of the vagus, inducing the secretory manifestations of vagotonia. In chronic gastritis we recognize as operative not merely the inability of the mucosa to form a complete secretion, but also the mechanism of neutralization of the secretion by the mucus. In ulcer we do not look for pathognomonic curves, for we realize that a nonobstructive ulcer gives a very different picture from pyloric stenosis with ulceration. In all forms there is a tendency toward vagotonia, pyloroplasm, hypersecretion, shortening of the interdigestive period, and increase in protein content. In duodenal ulcer, the most characteristic finding is that of positive blood at the phases of tryptic regurgitation. In a large group of duodenal ulcer cases there is present a late hypersecretion, accompanied by periodic regurgitation of duodenal material giving occult blood reaction. Gallbladder disease gives clean digestion and often high acidity without mucus, pus or blood, and when there is pericholecystitis, with adhesions to the duodenum, the adhesions closely resemble stenotic ulcer at the pylorus. However, there is a group of old gallbladder cases associated with duodenitis, in which a low curve with all the findings of true gastric infection may be detected. Appendicitis is most frequently accompanied by clean digestion, with high figures indicative of vagotonia. Cancer has as its characteristics the uniform and constant depression of secretory activity, together with the presence of its specific products, pus, blood, mucus, lactic acid, soluble protein, etc., each of which plays a part in the composition of the curve that is formed. These facts must be borne in mind. Nerve factors, circulatory toxins, the lack of building material, and direct local disease of the mucous membrane may all produce low acid curves, but they produce the curves very differently. The first and second each give a clean subacid curve, and the third is accompanied by elements such as mucus, pus and blood, which give a clue to its source. Let me illustrate: We can see in a certain anemia a low curve without any mucus, blood or pus; it is simply a subacid curve in anemia. The subacid curve in chronic gastritis is punctuated by the periodic secretion of quantities of mucus. In infectious gastritis, there is not merely mucus, but bacteria, pus and blood, and the same is true in case of carcinoma. Pericholecystitis with adhesions to the duodenum may give the same picture as contrasting pyloric ulcer, but blood and increased protein in the latter serve to distinguish it. We know that gallbladder disease, appendicitis, pancreatitis, intestinal adhesions and pelvic disease may all give reflexly vagotonia and the same gastric picture. It is the correlation of all the data which enables us to make the correct interpretation.

Some factors are important. The amino-acid content seems to run parallel to the curve of tryptic regurgitation. Pancreatic ferments or pancreatic regurgitation occurs independently of biliary regurgitation, particularly in the digestion of carbohydrates. With fats, both are likely to regurgitate.

In the analysis of blood, we attach great significance to the position and type of bleeding. Blood synchronous with periods of active tryptic regurgitation is characteristic of duodenal ulcer. Blood throughout the entire digestive phase of subacid cases is seen particularly in cancer and infected gastritis. Blood in the interdigestive period and not in the digestive cycle is likely to be swallowed blood. With pus we must distinguish between extragastric or swallowed pus and intragastric pus or that formed in the gastric wall. The former is always seen in the interdigestive cycle and is diagnostic; the latter is seen in both cycles.

The problems that confront us in the interpretation of gastric work are legion. Fractional analysis only emphasizes how many there are and offers a method for their solution. In the normal subject, we can produce high acid curves with meat, milk, low acid curves with fruit and vegetables, and we can produce an experimental subacidity or achylia with concentrated salt or glucose solution, or we alter the vagus and the sympathetic tonus by drugs and ductless gland preparations that alter the gastric response. Bacterial, chemical, neural, circulatory, and local mucosal disturbances can alter the gastric output, but only actual local organic disease can produce pus, blood, mucus and soluble protein bacteria.

Fractional gastric analysis already has an enviable record. It has emphasized the importance of the digestive and interdigestive cycles. It has enabled us to study the true residuum and to isolate and easily to diagnose swallowed suppurative material from infected processes higher up. It has enabled us to trace exactly the trend of digestion and depict the factors occasioning disturbance. It has opened up new chapters on psychic secretion, automatic regulation of acidity by tryptic regurgitation, and protein curves, and it has emphasized the fact that no one can guess the nature of gastric work but only painstaking technic will reveal all its details.

TOXINS AS DEPRESSANTS

Toxins of a bacterial nature usually act as depressants to the secretion. There are certain infections in the nose and throat, however, which unquestionably induce increased vagus tone and result in an increased secretion. In the analysis of the gastric curve, many points must be taken into consideration. Anomalies in the gastric secretion may be simply a perversion in secretory output but without the addition of evidence of local disease. For instance, gallbladder, appendiceal, intestinal, pancreatic and nervous conditions may give rise to well marked changes in the curve, either a prolongation of digestion, late hypersecretion, or other changes. But as soon as we have the addition of mucus, pus, blood, or bacteria, we are probably dealing with a pathologic process in the stomach itself.

Take, for instance, the question of delayed digestion, in which evolves a low, slow curve that is clearly pathologic. This curve is encountered in cases of chronic gastritis, late pulmonary tuberculosis, a group of anemias, chronic parenchymatitis, nephritis, a small group of old ulcers, and finally in a very large group of gastric cancer. In each case the mechanism is different, although in all there is the underlying disturbance in the mucous membrane, possibly primary in certain forms of gastritis and carcinoma, and clearly secondary in anemias, nephritis, hepatic disorders, cirrhosis and tuberculosis. In the cancer group, we see a disproportionate reduction in free acid and the presence of pus, blood, mucus, lactic acid, etc. In chronic gastritis we see simply a disproportionate amount of mucus. In some of the anemias and in nephritis there may be no increase in mucus, and free acid runs proportionate or parallel to total acidity. A cure may follow local treatment, it may follow treatment directed to the heart or kidneys, or again, curiously enough, these secretory delays may suddenly clear up after removal of a focal infection in the teeth, the sinuses, the tonsils, etc. I have case records in which the entire response was altered after such procedure. The whole problem is so complex that painstaking research alone will solve it.

We have been able to show that the delayed curve of acidity may come about (1) through a delayed elaboration of secretion on the part of the mucous membrane, (2) through a strong duodenal regurgitation neutralizing an apparently normal secretory output, and (3) through the neutralization of the secretion by pathologic products, such as mucus, pus and blood. The first form is accompanied by no evidence of either tryptic regurgitation, or mucus, pus and blood, and may be due to anemias or to circulating toxins, or may be the result of disease elsewhere altering the circulation of the nervous supply. The second form is shown by the evidence of regurgitation in laboratory study. The third form belongs to the group of true gastric infections and cancer. All of them are susceptible to careful analysis.

CONCLUSIONS

1. Fractional gastric analysis alone can reveal the evolution of gastric digestion. Gastric digestion, whether normal or pathologic, consists of a series of constantly changing phases. Certain phases are normal, certain are obviously pathologic.

2. Normal gastric physiology consists in a rhythmic series of cycles in which we may differentiate the digestive and the interdigestive periods. In health, they succeed each other regularly; in disease, their sequence is seriously interfered with.

3. The digestive cycle is the response of the stomach to a definite stimulus. The response is partly psychic and partly chemical, but in its essential characteristics, it differs from the interdigestive phase.

4. There is always a physiologically active secretion in the stomach but the characteristics of the two periods are very different. The digestive secretion persisting into the interdigestive period is pathologic.

5. Our studies of healthy men indicate that there is no acidity in disease which cannot be encountered in health, and the diagnostic value of high acidity must be very carefully worked out. Forty-five per cent. of more than 800 cases (normal) gave a total acidity of 100 in excess. Normally, we point out three different secretory types.

6. Pathologically every possible variation in secretory output occurs. At present it seems that there are many possibilities in the analysis of each variety of curve. It is at this point that circumstantial evidence by the study of the protein curve, pus, blood, mucus, bacteria and tryptic regurgitation may throw light on the subject. In every case the extragastric as well as the gastric causes must be reviewed.

7. The gastric response may be shortened, delayed or exaggerated. It may be accompanied by the most

marked variations in secretory and acid concentration output. It may be altered by the addition of pus, blood, mucus and bacteria in every possible way, and these variations may occur only at certain portions of the curve, emphasizing the necessity for complete examination.

8. The investigation of psychic secretion, tryptic and biliary regurgitation, hypersecretion, protein concentration and secretory velocity, and of the evidence of pathologic material is full of promise.

ABSTRACT OF DISCUSSION

Dr. A. F. R. Anderson, Brooklyn: A study of findings on fractional examination of gastric contents in about 800 patients leads to the following conclusions: The only curve of acidity which is of itself of absolute value in diagnosis is that found in achylia gastrica, a straight base line, representing free hydrochloric acid, running along the zero line, and a slightly varying curve of total acidity. The achylia of malignancy is quite often found to be associated with a high total acidity. The reflex type of curve is also of considerable value as indicating an inflammatory condition somewhere in the abdomen or pelvis, causing a reflex manifestation in the stomach. A finding which we consider typical of duodenal ulcer is the occurrence of blood and bile coincidently during the fractional examination. Trauma from the tip of the tube catching in the pylorus and being pulled on must be excluded, but sufficient trauma to cause bleeding is exceedingly rare. Pyloric obstruction will show the normal overnight residue and the usual findings of carcinoma or of ulcer. After gastro-enterostomy for ulcer, bile is usually present in considerable amount, and when blood is also present it may mean persistence of the original ulcer, or the presence of a jejunal ulcer. Gastric motility can be determined more accurately by the fractional method than by usual routine roentgen-ray examination. Cases of gastroptosis showing a normal or even a slightly increased motility by the test meal examination often show much residue six hours after the usual sized barium meal. When, subsequently, a smaller barium meal is given, normal emptying may occur.

Dr. William Van Valzah Hayes, New York: The practical question that comes up is, How can we, as gastro-enterologists, employ this sort of technic in the ordinary case? There are many pros and cons on the subject, and up to date I have not used the method very frequently. In the ordinary case, in addition to a careful history and careful physical examination, examination of the stool, etc., we want to find out what the stomach does in the early and in the late stages of digestion. Are we going to put in a tube which will make the patient uncomfortable, which will cause a continuous flow of mucus and other secretions, and more or less obscure certain phases of the gastric activity, or can we, with less trouble to the patient and to ourselves, get the data we need? I believe that in the average case we can get these data by simply giving the test breakfast and taking it out an hour later. Then the following day give a duration test, *i. e.*, two soft boiled eggs, a roll and a glass of water. Three and a half hours later use the tube to see whether the stomach has emptied itself as it should have, or whether there remains a considerable amount of gastric contents, with high acidity and possibly regurgitated blood or bile from the duodenum. Diagnosis is nearly always possible in this way.

Dr. Frank Smithies, Chicago: This is a practical method in the diagnosis and treatment of gastro-intestinal ailments. It seems quite impossible that apart from the diagnostic significance of these curves, an individual should fail to appreciate the importance that some of these curves carry with respect to treatment. One of the main points brought up during the past few years is the differentiation of gastric and duodenal ulcer. These curves enable us to differentiate quite easily the postpyloric from pyloric or antral ulcer. It seems that frequently it would be almost impossible in any other way to differentiate this class of case. Regarding the indications for treatment: There is no rule of thumb method of treatment of ulcer of the stomach or duodenum. There must be intense individualization of treatment. The treatment and the cure do not depend on anomalies of gastric secretion. Other factors come into play. The causes of ulcer indicate that in treatment we must first look to the individual factors in the production of ulcer. Afterward, if we give any medication, we must give it according to our knowledge of what the patient's stomach is doing. In many cases a great deal of medication is not needed. The work of Crohn bears out some of Dr. Rehfuss' observations, namely, that in the giving of alkali we very often cause more harm than good. We simply defeat nature in its attempt to secure in the stomach a restoration to normal.

With regard to the mucus cases Dr. Rehfuss mentioned: In these cases, where we have early secretion by the fractional method, within the first half hour or hour, and then have an accumulation, of a great deal of mucus, we are simply dealing with an instance where the gastric glands are easily fatigued, and the condition represents a form of gastric fatigue, with mucoid secretion instead of the specific secretion of that gland. We have seen it in patients who have been given great quantities of alkali. It is apparent from a knowledge of gastric physiology that what alkali does is simply to urge the stomach first of all to restore the natural reaction of the stomach contents, namely, faintly or definitely acid. To do this it must overcome a foreign body, namely, the excess alkali. It does this by first producing a great deal of acid, then there follows physiologic fatigue, namely, an excessive secretion of mucus, which has to be washed out. If more alkali is given, in the end, the stomach does not produce acids. In periods varying from six to twelve days there is no acid secretion whatever. The glands are putting out a great quantity of mucus. This indicates mucoid degeneration, or physiologic fatigue of the cell.

Dr. Martin E. Rehfuss, Philadelphia: Regarding Dr. Hayes' suggestion that this seems to be a little too extensive a procedure, a great majority of the men I have met do not think it is at all extensive. I do practically nothing else. My assistants are trained. I do not pass the stomach tube more than a few times a week. You can train nurses to do every little detail covering this work. It is a question of organization to do this work. It is absolutely impossible, by simple examination, to predict anything regarding the stomach. I have seen any number of people who were told that they had a normal stomach after a single examination.

Dr. Smithies mentioned glandular fatigue. We found that in the normal, healthy individual we can give a meal and develop a curve, and give a meal immediately after, developing the same curve, showing there was no glandular fatigue. However, we took students around the examination period, and not only found that we could produce physiologic fatigue, but also a form of nervous fatigue. We found a man who could not coagulate milk, and when he came back after a vacation the milk was beautifully curded, which shows the effect of giving it to him in that way.

The Asset of Good Health.—I am heartily in favor of this measure [bill for an addition to the Hygienic Laboratory], because it helps in the preservation of health. For years and years the medical men of the world have been trying to impress on the people this fact, that good health is the most valuable asset we possess. It is often said on the floor of this House that this war, as horrible as it is, will teach the American people many valuable lessons. And there is no doubt in my mind but that one of the most valuable lessons that will be taught in this war will be the importance of preventing disease. Today we understand as we never understood before that it it necessary not only to preserve the health of our boys on the firing line, but it is also equally necessary to preserve the health of the people at home, who are united and working earnestly to produce the necessities for these boys on the firing line. I hope that the American people especially will never forget this lesson, and that from now on they will be willing to appropriate the money necessary, so that medical men can experiment and carry on the work that is necessary in order to prevent disease, and not wait until people are sick and then spend ten times more to be cured.—Mr. Lazaro, *Congressional Record*, Oct. 2, 1918, p. 11944.

RENAL COMPLICATIONS OF PREGNANCY FROM THE STANDPOINT OF THE UROLOGIST*

HENRY G. BUGBEE, M.D.
NEW YORK

The important rôle played by the kidneys during pregnancy has long been a matter of serious thought. Recent investigations of metabolism and kidney function have broadened the general knowledge of this subject, but very little has been added by the urologist. The more careful study of pregnancy by the urologist in association with the obstetrician should lead to a diminution in the incidence of renal complications and a more rapid recovery, with less serious sequelae when lesions are found to exist.

The patients whom I have seen during pregnancy have all presented well developed complications, only then recognized. In these cases, one fact has appealed to me, namely, that too little attention is given to the individual woman when she first presents herself to the obstetrician. This fact holds good for private patients, who usually come for examination early in pregnancy, as well as for hospital patients, who present themselves late in term or when in labor. Less may be accomplished with the latter than with the former class. The environment, habits of life regarding exercise, eating, drinking, and the condition of the gastro-intestinal tract all receive little consideration. A complete examination, including the mouth, teeth, tonsils, accessory sinuses, chest and abdomen; careful palpation of the kidney and other viscera, coming lastly to the pelvic organs, should be made but seldom has been made. Often there has been a single analysis of a voided specimen. A chemical and bacteriologic examination of a catheterized specimen of urine, and, if the patient presents any urinary symptoms, a complete urologic examination should be but has not been made. The taking of pelvic measurements, the palpation of the uterus and adnexa, the examination of a voided specimen, and a few words of advice, will not go far toward anticipating and preventing renal complications of pregnancy.

The renal function is such an important factor during pregnancy that it is right to look on the pregnant woman in one sense as a urologic case. This is true to the extent of warding off complications by advice as to the proper management of the case, and actual participation in and continued observation of those presenting renal complications.

ETIOLOGY

Why are the kidneys particularly susceptible to lesions during pregnancy?

1. Being organs of elimination, they are called on to eliminate the toxins of the fetus as well as of the mother.
2. The skin is less active than normal, rendering little assistance.
3. The diminished activity of the woman leads to less activity in the organs of metabolism, poor digestion and sluggishness of the bowels, thus increasing the amount of toxic material thrown on the kidneys to eliminate.
4. The increase of toxic products passing through the kidney causes kidney irritation, which leads to congestion, thus producing an important predisposing factor to infections.
5. The lowered resistance of the patient allows focal infections to become more active.
6. Coexistent with the foregoing, more bacteria are thrown into the blood stream, and the kidneys, already congested, are fertile soil for infection.
7. Intra-abdominal pressure mechanically interferes with the normal function of the abdominal viscera.
8. When a preexisting kidney lesion is added, such as a renal or ureteral anomaly, renal tumor, or malposition of the kidneys, a chronic infection, chronic nephritis, or a calculus, as well as ureteral lesion interfering with drainage, the urologic aspect of the case becomes most important. Should not the kidneys be relieved of the load so far as possible? How may this be accomplished without a complete examination of the patient and attention to all details of bodily activity?

Recent investigations have given evidence to show that a large percentage of renal infections are hematogenous in origin. A case recently observed clearly demonstrated this point. The woman, seen during her eighth month of pregnancy, was septic. I was asked to see her because of the diminished urinary output, and the presence of large numbers of streptococci and colon bacilli in the urine. Blood cultures showed the same organisms. She died of general sepsis. At necropsy, conducted by Dr. Losee, of the Lying-In Hospital, multiple miliary abscesses were found in the substance of each kidney, sections of which showed the same organisms, while the kidney pelves presented no lesions.

While the transmission of infection from the colon or the bladder to the kidney by lymphatic extension or directly to the ureter from a diseased appendix or a broad ligament infiltration or along the ureteral mucosa when there is a deficient vesico-ureteral valve, is possible and probably does occur, these cases are rare.

The most important element, next to the supply of bacteria to the kidney, is a lowered kidney resistance from the causes already enumerated, or interference with kidney drainage. Pressure on the ureter from the fetus has been given as an important factor in this connection. The ureters, particularly the right, have been found dilated and filled with urine in about two thirds of the gravidae coming to necropsy. This has been attributed to torsion, stretching or kinking of the ureters due to the enlargement and dislocation of the pelvic organs, but not to compression, since the specific gravity of the pregnant uterus is said to be equal to that of the intestinal mass. The pressure in the pelvis of the kidney is only 10 mm. of mercury, so that slight causes may lead to the stopping of the flow of the urine in the ureter.

Ahlberg found bacteriuria in 15 per cent. of pregnant women. Neibel found the urine sterile in only 25 per cent. of cases, demonstrating the presence of streptococci, staphylococci, and colon bacilli. Bacteriologic examination of the urine of all pregnant women should be made. The establishing of the relationship of bacteriuria to eclampsia and nephritis would be valuable.

---

*Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

*Because of lack of space, this article is abbreviated in The Journal by omission of the bibliography. This will appear in the Transactions of the section and in the author's reprints.

The majority of patients whom I have seen have presented active symptoms due to infection. If there was drainage, these symptoms were vesical (frequency, burning, painful urination); if drainage was absent, the symptoms were pain in the flank, tenderness in the costovertebral angle on one or both sides, and often tenderness in front, and in some cases the kidney could be palpated. When drainage is poor, the patient has an elevation of temperature, which is often associated with a slow pulse.

EXAMINATION AND RESULTS

Cystoscopic examination of a pregnant woman is seldom difficult. The patient is usually seen between the fourth month and term. The bladder is flattened from above downward, on account of pressure on the fundus from the enlarged uterus. Enough fluid must be injected into the bladder to elevate the uterus from the trigon, when with a close-vision cystoscope with the beak well depressed, the ureteral orifices are easily distinguished and catheterized. When the ureteral catheter is passed, a moderate amount of pressure may be necessary to advance the catheter on one or both sides. In some cases there is a tendency to an obstruction, and whether due to torsion or kinking of the ureter, or pressure on the ureter, it is found more often on the right than on the left side, and between 10 and 20 cm. from the bladder. When the catheter enters the renal pelvis, there is often a rapid flow of cloudy urine or thick pus, which diminishes in rapidity until it comes down to normal excretion. Complete ureteral obstructions were encountered in the series examined, and demonstrated to be due to calculus, kink, and pressure on the ureter from without. Roentgenograms were taken with catheters in position in certain cases, and in the complete obstructions a thorium injection was made.

In 90 per cent. of the cases observed, the infection was due to the colon bacillus. The bacilli were found on both sides in 75 per cent. of the cases, but in all the infection was more severe on one side than on the other. The kidney function was diminished in all.

A routine pyelo-ureterogram has not been justifiable, owing to the condition of the patients.

It has been my practice to do as little manipulating as possible in these cases. In the infections the patients are often acutely ill, and no more should be done than is necessary to give immediate relief of the symptoms. This means establishing drainage.

UNUSUAL CONDITIONS, WITH ILLUSTRATIONS

Several unusual conditions were encountered, and I shall enumerate them briefly.

One patient, a woman aged 26, presented a unilateral chyluria, with no demonstrable lesion. Aside from the presence of a large amount of chyle in the urine from the left kidney, the examination and pyelograms were negative. This condition had been present when she first menstruated and during the puerperium with her two previous children, but had appeared at no other time.

A woman four months pregnant developed pain in the right upper quadrant, and a firm, irregular mass appeared. A catheter was passed into the right renal pelvis, resulting in a rapid discharge of clear urine, which was free from infection. A pyelogram showed a hydronephrosis. An abdominal exploration revealed a large fibroid attached to the right side of the fundus of the gravid uterus, which pressed on the right ureter. The fibroid was removed, with relief of symptoms, and the patient went to term.

Urgent bladder symptoms during the fourth month of pregnancy were found to be due to a pyelonephritis occurring in a pelvic kidney, in a woman who had previously complained of no urinary symptoms.

Profuse hematuria, localized as unilateral, occurring in a woman five months pregnant, was not relieved by pelvic lavage, but ceased two weeks after the uterus was emptied. Another case of hematuria, the source of bleeding being the left kidney, came under observation when the patient was two months pregnant. Complete urologic examination showed deficient function of this kidney, but no evidence of infection. The patient had a positive Wassermann reaction. The bleeding ceased after the administration of arsphenamin.

Bilateral polycystic kidneys were demonstrated in a patient five months pregnant, who had not previously noticed any urinary or abdominal discomfort.

A ureteral calculus causing ureteral obstruction was found in two cases during pregnancy. In the one, the calculus was passed following cystoscopic manipulation. In the other the calculus was removed, the patient going on to term.

Sharp angulation at the ureteropelvic junction was demonstrated by pyelo-ureterogram in three cases in which there was a complete blocking of the ureter.

I have drained a perinephritic abscess in two patients immediately following delivery, the infection of the kidney arising during pregnancy, but not being recognized until after confinement.

Pyonephrosis, with an acute infection occurring during pregnancy, and renal calculi have been noted in two cases, in both of which the patients were temporarily relieved by pelvic lavage and were carried to term.

More than 90 per cent. of the cases observed have been acute infections, most marked on one side, occurring during the last three months of pregnancy. The patients were suffering from absorption, high temperature, pain in the side, and urinary symptoms. These patients were all catheterized, given pelvic lavage, and in many the ureteral catheters, one or both, were retained from twenty-four to forty-eight hours. All were relieved and went on to term.

A typical case of this group was a woman, aged 25, with a history of good health until this, her first pregnancy. During the first two months she suffered from severe nausea and vomiting, resulting in irregularity of her diet. She remained in bed most of the time, became constipated, and during the third month had a stool only after taking a cathartic, often going three days without an evacuation of the bowels. During the fourth month she developed frequent and burning urination. When I saw her she had had a chill, followed by fever and slight pain in the back, two days later, tenderness in the loin, and more urgent urinary symptoms. Cystoscopic examination showed the bladder intensely congested. There was retention of urine in the left renal pelvis. This urine contained pus and colon bacilli. The kidney function was diminished. The right kidney showed a milder infection. Pelvic lavage, with retention catheters in the kidneys for thirty-six hours, resulted in a drop of temperature from 103 F. to normal, and complete relief of symptoms. The knee-chest position for the relief of pressure for twenty minutes to an hour a day, a second pelvic lavage at the end of three weeks, and careful attention to the gastro-intestinal tract, gave lasting relief, and the patient went to full term. Six months after confinement specimens taken from each kidney showed only a diminished function of the left kidney. This woman became pregnant a year later. Most careful attention was given to diet, exercise and bowels from the outset. Once during the third month, slight urinary symptoms appeared, and lavage of the kidney pelvis was given at once, with complete relief. The patient went through this pregnancy with no further complications.

In hospital service, patients often enter the hospital in labor. They seem sicker than normal, and not until after delivery is a renal infection discovered.

Not only is it important for the immediate welfare of the pregnant woman to give her all the relief possible when a renal infection exists, but for her future health. If one takes a complete history of a woman applying for relief of urinary symptoms, very often is it found that the active symptoms date from pregnancy. The possibility of some earlier lesion even from childhood, such as nephritis complicating an infectious disease, or a renal injury, should be ascertained, the existence of which may have rendered the kidney more vulnerable during pregnancy.

The possibility of preexisting but symptomless disease in the kidney, or of actual lesions as enumerated, giving lowered resistance, may play an important rôle in predisposing to kidney lesions during pregnancy.

Movable kidneys due to poor drainage are particularly prone to infection. A kidney previously normal when congested from the irritation of toxic products from the intestinal tract, and of large numbers of bacteria, develops a pyelonephritis which may or may not be recognized during pregnancy, but which leaves the organ permanently damaged to a greater or less degree, leading to future trouble. Therefore, not only should lesions be recognized and immediate relief be given to carry the woman through pregnancy, but after the pregnancy she should be observed until the maximum amount of permanent benefit has been derived by palliative or radical measures. Unquestionably many serious kidney lesions of later life will thus be avoided. Once the seat of an infection, a kidney is always more vulnerable. Few women who have gone through a pregnancy have the same general tone as before. Relaxed abdominal muscles, impaired perineal support, greater tendency to constipation from the foregoing causes, and a more sedentary life predispose to future renal infections, and many of the cases of frequency of urination seen in women later on in life are but relapses of the old infection or reinfection in kidneys once damaged during pregnancy. How easy it is for a bladder, possibly with weakened support, emptying poorly or subject to pressure from pelvic displacements also secondary to pregnancy, to become infected from the urine from such kidneys, and to cause distressing symptoms for years!

TREATMENT

The treatment resolves itself, first, into prophylaxis. Such infections may be prevented by impressing on the obstetrician and general practitioner the important rôle of the kidneys during pregnancy. He should go into the history of his patient more carefully, the catheterized urine should be examined bacteriologically as well as chemically, and any variation from a normal condition should be an indication for a complete urologic examination.

Closer attention should be given to the metabolism of the patient, especially in the intestinal tract, thus eliminating as fast as possible the amount of toxic products of intestinal putrefaction thrown on the kidneys, not by the administration of cathartics, but by exercise, diet, and plenty of fluids. This also means diminution in the number of bacteria passing through the kidneys. In this connection, the importance of eliminating focal infections, whether oral, nasal or otherwise, cannot be overestimated.

When a pathologic condition in the urinary tract has been found which might predispose to a kidney infection, it should be eliminated early in pregnancy if possible. Patients as a rule withstand treatment and operation during the early months of gestation with remarkably little reaction. Whether or not a woman should attempt to go through a pregnancy with a renal lesion present, thus subjecting the kidneys to the added strain and possibly infection, is a question to be decided in each case.

Renal anomalies, tumors, calculi, and infections come under this consideration, and some surgical measure—nephrectomy or nephrotomy—may be advisable at once.

In the presence of such lesions, relief of the kidney to the extent of diminishing its load is certainly indicated, and consists of the most careful attention to details.

When a kidney infection is already present, the indications are to give relief from the toxemia by establishing drainage, and to cut off the supply of toxins and bacteria. This means kidney drainage with the ureteral catheter, retention of the catheter if necessary, lavage of the kidney pelvis, free fluids by mouth, colonic irrigation, and lastly, urinary antiseptics. If relief is not obtained, termination of the pregnancy is to be considered, and, lastly, some operative precedure, such as drainage of the kidney or nephrectomy, if one kidney is the source and relief cannot otherwise be obtained. Following immediate relief, the patient must have the closest attention during the remainder of the pregnancy to prevent a recurrence of the acute infection. A shifting of the intra-abdominal pressure gained from the knee-chest position is valuable and all other measures noted in prophylaxis are important.

When a patient has passed through the labor, she should be treated as a urologic patient until all damage has been repaired to its fullest extent by treatment or operative procedures. The possibility of future trouble must always be considered and guarded against.

ABSTRACT OF DISCUSSION

Dr. Herman L. Kretschmer, Chicago: My experience has been that these patients come to us very late. The general practitioners who carry these women through pregnancy do not seem to realize the importance of watching their condition carefully and of making routine examinations of the urine. Generally, when we are consulted, the patient gives a history of bladder distress extending over varying periods of time. They are often treated for retained placenta, sepsis, malaria, appendicitis, etc., and the real cause of the symptoms goes unrecognized. Finally, the urologist is called late in the course of the patient's illness, whereas he should have been called in at an earlier stage. In many of the cases I have made a special effort to elicit a history of previous bladder distress. I think that many of these cases are a "lighting up," by reason of the pregnancy, of conditions from which the patient was suffering before becoming pregnant. I found that some of them had had pyelitis in infancy. Several patients have referred back to their school days when they would tell that they had had bladder distress. In several cases patients had indefinite histories; several had been subjected to the removal of the appendix, with or without temporary relief; so that often the real cause of the trouble is not recognized.

I was interested in the effect of pregnancy on pyelitis in patients whom I cured, and who became pregnant again. I have had occasion to see two or three of these women. When discharged they were cured, as their urines were sterile and free of pus, and they did not develop pyelitis in subsequent pregnancies. The importance of examinations before, during and after pregnancy cannot be emphasized too much.

In approximately 90 per cent. of cases the infection was due to the colon bacillus. In one or two a pure culture of streptococci was obtained. All patients had residual urine, in the kidney or kidneys.

One point deserves special emphasis, and that is the question of treatment. I agree entirely with Dr. Bugbee about prophylactic treatment and about carrying these patients through till they are well. Often they go to the family doctor or to the obstetrician, who knows but one treatment, and that is to empty the uterus, because following this procedure the acute symptoms disappear. These patients are not cured because there is nothing done to cure the infection. At least half of my cases were cases seen in consultation with the obstetrician, and in each and every instance the obstetrician advised immediate emptying of the uterus; and in each instance this procedure was not carried out and the patient went on to full term without any operation.

Dr. John R. Caulk, St. Louis: In every locality we seem to have the same trouble with the obstetrician and the general practitioners. We must train them to realize the importance of renal complications during pregnancy, and particularly infections; and teach them to protect their patients by investigation before and during pregnancy in order to avoid focal infections of various sorts. Most of these women probably have had pyelitis before. They may have had an infected kidney or renal retention. Retention more than anything else that predisposes to these infections during pregnancy, and the rapidity of cure depends a great deal on the duration and the extent of the retention, and how much the musculature of the pelvis has been overstretched, just the same as in bladder retention. It is surprising how quickly a kidney which has been overdistended for some time will rapidly come down to its normal capacity, and the temperature and toxic processes will abate. We must get the obstetrician acquainted with the fact that he must quit ascribing everything to pyelitis and giving hexamethylenamin. We have not appreciated the value of ureter catheter drainage. It is not only applicable to pregnancy, but can be applied to all acute renal retentions. In cases with pure pus exuding from the ureteral orifices, with no function on that side, and the other side functioning normally, one unblocking will at times effect a cure. It is surprising that the kidney does not require surgery, resuming its function within a week or ten days. A kidney with retention which shows a very slow phenolsulphonephthalein output, which looks as though it should be attacked surgically, will often come back to normal usefulness by catheter drainage. There is no question that we cannot only save the kidney but the individual, and we will not have the operations or abortions we are having right along.

Dr. V. D. Lespinasse, Chicago: This discussion seems to have drifted more into a discussion of infections of the kidney that occur during pregnancy and are exacerbated by the presence of pregnancy. I have been much interested in the kidney of pregnancy from the standpoint of true renal complications without infection. We were enabled to reproduce this noninfected kidney of pregnancy experimentally by making a symbiosis between a small individual representing the baby and a large individual representing the mother, completely joining their circulations; and in that way we have obtained some very beautiful specimens identical with eclamptic organs. The organs (kidney, liver and spleen) show a cloudy swelling, focal hemorrhages and complete degeneration. When you do this with individuals not of the same blood group you have a much greater effect, a much larger hemorrhage. These changes are not limited to the kidney only, but involve the liver and the spleen—a most intense poisoning. This irritating substance, characteristic of pregnancy, is the material that causes all this lighting up of old and the development of new infections. The kidney, spleen and liver have been compromised, their blood supply is interfered with, and if a colon bacillus is in the neighborhood it localizes in the kidney and produces a so-called pyelitis.

Dr. A. E. Goldstein, Baltimore: Ever since Dr. Caulk's paper two years ago on these cases of pyelitis in pregnancy I have been interested from the standpoint of renal insufficiency, particularly as to the blood urea. In pyelitis there is retention and also decreased function. By the use of ureteral catheters, allowing them to remain in place twenty-four to forty-eight hours, the blood urea decreases and the phenolsulphonephthalein increases, thereby avoiding forced deliveries in many cases of pyelitis of pregnancy.

Dr. Henry G. Bugbee, New York: I had a patient who gave a history that in thirteen days she had not passed any urine. Three weeks previous to the suppressing she had had a cauterization of the cervix for carcinoma. I found on examination that there was no urine in the bladder and that both ureters were obstructed about 2 c.c. from the vesical openings. We operated on this woman and found that a cicatrix had formed which involved both ureters, closing them off completely. Each ureter was about the size of one's thumb. We cut off each ureter at the lower end as close to the cicatrix as possible, and then implanted it into the top of the bladder. Her kidneys functionated at once and have continued to ever since.

IMPORTANCE OF BEDSIDE INSTRUCTION IN THE TEACHING OF THERAPEUTICS

FRANCIS H. WILLIAMS, M.D.
Senior Visiting Physician, Boston City Hospital
BOSTON

There is, I believe, a gap between the instruction given in materia medica, pharmacology and therapeutics on the one hand, and the requirements of medical practice on the other, which, were it filled, would assist in making therapeutics even more valuable than at present. Let me recall the detailed instruction given to students in the comparatively few things employed in the surgical treatment of patients. An example is afforded by the instruction in the use of splints and bandages. The students are not only taught in a general way how and why these are used, but apply them repeatedly, the work being done in small sections. Students should be trained in a similar manner in the medical treatment of patients. The power in the hands of the physician does not display itself so dramatically as that in the hands of the surgeon, but it is no less essential, and opportunities for its use are more frequent.

Not only must a subject so unusually complex as therapeutics be presented in lectures and recitations, but also more opportunity should be afforded for bedside instruction, given by a physician who has had a training in pharmacology, as well as a clinical experience. To illustrate, let me describe some exercises of the character I would advocate, which I gave about thirty years ago. The students were taken into the wards in small sections, not exceeding eight in number, and standing about the patient's bed were given the diagnosis, together with a brief outline of the case. They were then told to consider that the patient had come to them for treatment, and, after any questions which they wished to ask had been answered, were required to write, on blocks of paper which had been distributed to the section, what they would do if the patient were their own. This was not limited to the use of remedies, but included directions as to diet, occupation, habits of life, etc. These outlines were handed to the instructor, and as some were ready sooner than others, there was sufficient time for him to look over each paper without delaying the exercise. The papers usually fell into three groups: one in which the students had done well; another in which they had outlined a treatment which was incomplete; and a third in which they had made serious mistakes, for example, in choosing the wrong remedies, or in giving them in an amount or in a way which would fail to be of any value, or in such a way or such an amount that harm might be done. Comments were made freely by the instructor, so that all received the benefit of what was good, as well as the warning involved in the mistakes made. As names were not mentioned, the comments were impersonal and could thus be made more emphatic. A most convincing evidence of the need of instruction of this nature was afforded by the character of many of the answers written at these exercises. After the students had done their best, and had been told why some of their directions should not be followed, they had an opportunity to see how the physician met the situation. At subsequent visits the results of treatment could be noted.

In these exercises the instructor, when prescribing a laxative, a hypnotic or an analgesic, for example, was able to recall briefly to the minds of the students the important members of the group from which it was chosen, and give the reasons for his choice, why it was especially adapted to the patient's condition, and the precautions which should be taken to promote success and avoid harm. In order to emphasize still further the clinical side, the final examination in therapeutics included not only the usual written examination, but also an oral examination, which gave a better opportunity to bring out the proficiency of the students on this side of the subject.

In connection with the exercises described above, but in larger sections, the students had two or three others in which they were shown how a hot-air bath should be given, methods of administering remedies, of feeding, etc., and also some demonstrations by trained nurses. A young practitioner recently confided to me his perplexity when, as a house officer, he was told to give a patient a hot-air bath; he had never seen it done and did not know how to go about it. For a medical student to have an opportunity to see such demonstrations once, with explanations, is sufficient.

This method of instruction, namely, requiring each student of a small group at the bedside to state what he considers the proper treatment for the patient, under the oversight of an experienced physician who has had a training in pharmacology, is not used in our medical schools, so far as I can judge from the catalogues of more than twenty of our best schools. Incidentally, I noted that in more than one half of these there was no professor of therapeutics. This subject is one of the most important in the course, and every medical school should have, I believe, such a professor, who should be in touch with all instruction concerning medical treatment in the school.

Let me quote here a sentence from a statement made about thirty years ago, as a result of my experience with this method, a copy of which I came across recently:

> I believe that bedside teaching of therapeutics is of the first importance to students, to practitioners and to the community, that no other method is so well adapted to show students how the obstacles in the way of giving relief to patients are to be overcome, or to have the practitioner know how to distinguish between what is of service to the patient and what is harmful, to have him appreciate the dangers of new or absurd methods of treatment, and understand how to carry out safely and advantageously the many means of relief which are at our command, and of which it is sometimes very culpable for the practitioner to be ignorant.

This method gives the student an opportunity to realize the limitations of treatment, to appreciate the need of judgment and courage to use a powerful remedy in such amounts and in such a way as the occasion demands, and to gain a sense of values, that is, to see the problem of treatment in perspective, a difficult thing for many minds to acquire in any subject. It also offers another opportunity for joining the experimental method which prevails in the laboratories of chemistry, physiology and pharmacology, with the observational method for which the clinic affords such a wide scope, and leads the student to form habits of thought which make him a better practitioner and more truly a professional man.

In didactic teaching it is impossible to present the subject of therapeutics in a manner suited to the minds of all members of a large class; probably only a minority of them are reached. On the other hand, with small sections, at the bedside, the instructor comes in contact with the individual student and his difficulties, and may thus appreciate what he has failed to grasp. It is an advantage to have the bridge that connects the teaching of therapeutics with its application in practice built and used in the medical school, where the student can have assistance in this difficult task, rather than that unaided he should attempt its construction out of what he has heard in his lectures and recitations on the one hand, and his clinical inexperience on the other.

My plea is for a careful, painstaking rehearsal at the bedside by the student of what he is to do as a practitioner. Let him first be trained without taking responsibility, and when the time comes, this training will help him to give a good account of himself in his fight against disease, and to choose and carry out the proper measures.

The Nightcap.—W. J. B. Selkirk in the *Lancet* (London), Sept. 7, 1918, sets forth the advantages of the nightcap (not the liquid one) for the promotion of sleep. He believes that our grandmothers and grandfathers did not wear the nightcap as a matter of vanity, but that their experience proved that it was an aid in the wooing of Morpheus. He says this experience is confirmed by that of soldiers in the present war who wear the knitted helmet in camp and billet and dugout, and who find its warmth most soothing and comforting and promotive of sleep. He says it might be used with benefit by civilians suffering from insomnia not of gross organic origin. In addition to keeping the head warm, especially for those whose natural head covering has become sadly thinned or has disappeared for the most part, the cap or helmet also acts as a sleep promoter by shutting out extraneous sounds, thus helping to decrease the intensity of sense impressions which distract the would-be sleeper from the work in hand. In this connection he calls attention to the custom of soldiers (and many civilians too, perhaps) of imitating the habit of the dog which sleeps curled up, with his nose covered, and of the bird which sleeps with its head under its wing, in pulling the blanket completely over his head to facilitate sleep. In this manner he not only keeps his head warm and shuts out disturbing noises and other exciting sense impressions, as by the use of the nightcap, but by rebreathing his own carbon dioxid he half anesthetizes himself so that he sleeps soundly and wakes slowly, even passing through a more or less confused phase resembling the waking from a brief anesthetic state. While not to be recommended from the standpoint of healthful, refreshing sleep as in fresh air, this habit does promote sleep as does the now discarded nightcap of our grandparents.

THE PROBABLE ENDOCRINE ORIGIN OF PEPTIC ULCER *

G. A. FRIEDMAN, M.D.
Clinical Professor of Medicine, New York Polyclinic Medical School and Hospital; Gastro-Enterologist, Gouverneur Hospital
NEW YORK

The consensus of opinion is that chronic ulcer in man develops from the acute ulcer, and that the acute ulcer must necessarily be preceded by an initial lesion. Once the initial lesion is formed, its further development through the various stages into the chronic ulcer is attributed to the corrosive action of the hydrochloric acid of the gastric juice. However, intrinsic causes, such as the mechanical irritation of food on the ulcerated area, and extrinsic causes, such as epigastric pressure from abnormal posture, are other agents helping to produce chronicity. The presence of hyperchlorhydria in conditions other than ulcer, and the absence of ulcer in true achylia gastrica, though occasionally lesions in the stomach may be present in the latter condition, are facts suggesting that hydrochloric acid is a secondary, though prominent, factor in effecting the beginning of an ulcer. It is not the main etiologic factor.

Various theories have been advanced explaining the cause of peptic ulcer. Of these, the hypothesis based on the endocrine origin of ulcer is most probable. It attributes the initial lesion primarily to a disturbance in internal glandular secretion, which causes a disturbed equilibrium in the vegetative nervous system, both vagus and sympathetic, and consequently, functional disturbances in the various organs supplied by these nerves. Eventually, the continued functional disorder produces pathologic lesions and clinical symptoms.

CAUSES OF INITIAL LESION

Briefly stated, the initial lesion is attributed to an interference with the blood supply in a limited area of the gastric or duodenal mucous membrane. The circulatory disturbance may be, first, an ischemia of that part of the mucous membrane involved as a result of a spastic contraction either of the small artery or of the musculature surrounding that artery, both instances causing the occlusion of the artery; or the circulatory disturbance may be, second, a stasis of the blood in the small artery, either through vasodilatation or through pull on the vessel wall by relaxation of the musculature surrounding that vessel. Be it stasis or spastic contraction, there is an interference with the blood supply and hence with nutrition. To this is attributed the origin of the initial lesion, and subsequently ulceration takes place.

Because of an irritation arising from disturbances of internal secretion, the terminal nerve fibers of the vagus may produce a spastic contraction of the muscularis mucosae in localized areas, causing an occlusion of the smallest arteries contained in those particular areas. This continued spastic contraction of the musculature gradually causes an ischemia of the area supplied by the blood vessel. This ischemia interferes with the nutrition and, with the aid of the corrosive action of the hydrochloric acid, ulceration results. The same is true for spastic contraction of the vessel wall itself. The initial lesion, however, need not necessarily arise from vasoconstriction. It may originate from dilatation of the vessel. Because of reduced stimulation of the splanchnic nerve or through pull on the vessel walls by relaxation of the surrounding musculature from the diminished vagus stimulation, stasis of the blood in the smallest arteries occurs with an interference to nutrition. The next step is ulceration. But the vegetative nervous system, vagus and sympathetic, is fundamentally the main etiologic factor, for it originally affects the blood vessels or muscles causing the constriction or dilatation, contraction or relaxation. The vegetative nervous system in turn is dominated by the glands of internal secretion.

What may be assumed possible for small areas of musculature is a well known fact for larger areas. Gastrospasm, pylorospasm, etc., or gastric atony exist without the presence of ulcer. The fact that peptic ulcer is associated frequently with hypertonic or spastic stomach does not permit the assumption that the hypertonicity or spasticity is due to the ulcer. Were this true, one would not find ulcer associated with the subtonic stomach. It is not unreasonable to suppose, however, that the ulcer, once developed, sustains the spasm. Disturbances in motility, therefore, occur independent of ulcer.

Gastric atony or gastric spasticity is attributed to gastric neurosis, due to a disturbed equilibrium in the gastric nerves. This may manifest itself independent of the ulcer, but the existence of the ulcer is impossible at least without the local neurosis. This gastric neurosis is due to a disturbance in one or more of the endocrine glands. The disturbance is purely a functional one and has been termed ductless gland neurosis. To recapitulate briefly, the initial lesion of ulcer is due to (1) the ductless gland neurosis; (2) the influence of this neurosis on the vegetative nerves, resulting in the (3) gastric neurosis with atony or spasticity; (4) the disturbed circulation, caused by (*a*) ischemia from vasoconstriction of the small arteries or from pressure by the spastic contraction of the muscularis mucosae, or (*b*) stasis from vasodilatation, or by pull of the musculature on the vessel wall; (5) subsequent ulceration; (6) etiologic factors in the production of chronicity.

ETIOLOGY

Ductless gland neurosis was first emphasized by Bauer[1] and later by Hemmeter,[2] who states that there are cases of exophthalmic goiter which were characterized by all the phenomena of that disease, but which were not relieved by thyroidectomy and in which parts of the removed thyroid were found to be normal. No hyperplasia of secreting vesicles, no liquefaction of colloid material and no small round cell infiltration were noted. Cases are reported in which the full clinical picture of exophthalmic goiter developed in women with a rather sudden onset due to mental excitement.

According to Canon,[3] violent emotion causes an output of epinephrin from the suprarenals. Such repeated functional disturbances in the suprarenals may lead eventually to cessation of gastro-intestinal movement, dilatation of the bronchi, increased blood pressure and glycosuria. All these phenomena may be produced experimentally by the intravenous injection of epinephrin.

[3] Canon, W. B., and de la Paz, D.: Emotional Stimulation of Adrenal Secretion, Am. Jour. Physiol., 1911, **28**, 64.

So, too, exophthalmic goiter, at least at the very beginning, must be a functional disease. Likewise, glycosuria or mild diabetes may show the islands of Langerhans in the very early stages of the disease to be normal; or even achylia gastrica, which is probably at first a true neurosis, may be at the very start a functional disturbance, but later on may show a pathologic lesion, namely, atrophy of the glands.

Depressive states, on the contrary, may produce suppression of the thyroid secretion or suppression of the epinephrin secretion. It seems that in exophthalmic goiter not only excessive quantities of sympathetic and vagal products pass into the blood stream, but also epinephrin. This is proved from the researches of Leo Adler[4] and others who found in the blood serum of all patients suffering from exophthalmic goiter a high percentage of epinephrin. The symptoms and signs therefore in exophthalmic goiter will vary, depending on the excesses of the various chemicals entering into the blood stream from the thyroid.

The effect of the various secretory products of the thyroid on the gastro-intestinal tract is of vast importance. The thyroid has a double innervation, sympathetic and vagus. If the sympathetic products predominate, a condition which occurs in the majority of cases of exophthalmic goiter, anacidity or hypacidity will be found, since sympathetic products inhibit gastric secretions to a great extent. In instances in which the sympathetic and vagal products are discharged in equal quantities into the circulation, hyperchlorhydria may be found. The pure vagotonic type of exophthalmic goiter, although assumed by Eppinger and Hess,[5] is rare. However, in many cases of exophthalmic goiter the effect of vagal excitation is evident, namely, gastro-intestinal disturbances, vomiting and profuse diarrhea, all being manifestations of a thyrotoxicosis.

Crotti[6] states that the stomachs of patients with exophthalmic goiter in whom the gastro-intestinal symptoms are most pronounced, on repeated fluoroscopic examinations, show a state of more or less constant spasticity. There are, however, those patients with exophthalmic goiter who are obstinately constipated. In such persons few vagal signs are noted, and the constipation may be due to increased intestinal inhibition from the sympathetic excess. Furthermore, Iscovesco[7] has isolated from the thyroid a lipoid substance, injections of which into animals produced the typical picture of thyrotoxicosis. All these facts indicate that exophthalmic goiter is a mixed neurosis attributed to an overproduction of sympathetic and vagal products of the thyroid. Thus the sympathetic overflow manifests itself chiefly on the secretions of the stomach, and the vagal on the peristalsis. All grades of functional disturbances may occur from very severe to very mild. Again, there may be an overproduction of the sympathetic products or there may occur a disturbance in the thyroid gland in which the vagal products will be produced in larger quantities than the sympathetic, or both vagal and sympathetic may be manufactured in excessive amounts, as happens in cases of exophthalmic goiter with severe gastro-intestinal disturbances. Small quantities of vagal products, due to minor disturbances in the thyroid, may lead to marked alteration in the peristalsis and secretion of the stomach. Such a mild vagal neurosis may be the underlying cause of the gastric neurosis.

Suprarenal insufficiency, however, may influence the peristalsis and secretion in the same manner as occurs in vagal thyroid neurosis, for the sympathetic impulses are diminished, and, as has been discussed elsewhere, suprarenal deficiencies mean various grades of vagotonia. There are no reports of fluoroscopic findings in Addison's disease, but in two cases, the gastric analysis showed hyperchlorhydria, and in addition, blood examination showed an eosinophilia, both findings being common in vagotonia.

The sluggish digestion and atony of the stomach and the bowels in myxedematous patients are quite characteristic. Anacidity and hypochlorhydria is the rule in this condition. The cause of the diminished secretion is slightly different from that observed in exophthalmic goiter, since in the latter it is caused by sympathetic inhibition, while in the former by diminished vagal excitation.

The decreased peristalsis of the gastro-intestinal tract in a myxedematous patient is attributed to an absence of the vagal products of the thyroid in the blood stream, as a result of depressive causes leading to the vagal neurosis in that gland. Lane,[8] for instance, believes that intestinal stasis is due to subthyroidism. Since epinephrin inhibits intestinal and gastric peristalsis, a condition similar to the peristalsis observed in myxedema should be expected in hyperfunction of the suprarenals or in the suprarenal neurosis of suprarenalemia.

Parathyroid insufficiency seems to lead to spasticity of the stomach. In two cases of ulcer with tetany, Bine[9] reported the presence of pylorospasm. Thus, parathyroid hyperfunction must have an inhibitory effect on peristalsis.

The pituitary body, the action of whose products are on the extended vagus or pelvic nerves, may be excluded from consideration in regard to gastric peristalsis, and, hence probably plays no rôle in the origin of the initial lesion of ulcer.

Hypersecretion or hyposecretion are secretory disturbances found in gastric neurosis and peptic ulcers. The secretion of the duodenal mucosa shows its effect on pancreatic and intestinal secretion through the blood stream, and Edkins gastrin, or as Starling calls it, "gastric secretin," shows its effect through the same route on gastric secretions. The secretins are endocrine products of the gastric and duodenal mucosa. Gastrin belongs to the same class of hormones as the duodenal secretion, which, according to Fürth and Schwarz,[10] is a mixture of several substances possessing the properties of exciting secretion, of which the most important is cholin. Cholin is essentially a vagotrope substance, which in excess may excite the secretory vagus fibers, and in deficient quantities may cause suppression of gastric secretion.

Although these products, or, as Starling calls them, chemical messengers, act directly on the glands through the blood stream, they may also influence the secretory fibers of the vegetative nerves. Since the true ductless glands exert their influence on the vegetative nerves, the influence of these glands directly on the secretions of the stomach and the bowels is probable.

One must not, however, deny the influence of the central nervous system on the gastric secretion. This is evident from the effect of the sight, smell, and taste of food on the secretion of gastric juice. Through the epoch-making works of Starling, Pawlow, Canon[11] and others, it became a known fact that the maintenance of the body is to a large extent independent of the central nervous system.

Through the plexuses of Meissner and Auerbach, acting conjointly with the sympathetic ganglions, the central nervous system has apparently a minor influence on the gastro-intestinal tract, but the processes of digestion are still controlled by hormones. In regard to the gastro-intestinal peristalsis, however, the central nervous system, together with a reflex mechanism, must be considered. Thus, for instance, the acid secretion which is elaborated in the gastric mucosa, causes the pyloric sphincter to relax at regular intervals; and also, as another example, the movement of the intestines is provoked by the bowel contents. It is not unreasonable to assume that there is also a nervous reflex, which is set in motion by the secretion of the gastric and intestinal mucosa to control peristalsis. Still, one must admit that the movements of the stomach and bowels are chiefly regulated by the chemical communication from one part of the intestine to another or through the agency of products from the endocrine glands circulating in the blood stream and acting directly on the nerves or musculature.

Altered function in the endocrine glands, therefore, will lead to altered peristalsis. This possible dependence of the disturbed peristalsis on the products of internal secretions was suspected by William Mayo,[12] in a paper of 1907, in which he said: "The curious blending of the sympathetic with the ductless glands is exemplified in the suprarenals, thyroids and parathyroids. Here we may possibly get an explanation of that close association which exists between pyloric spasm, atonic dilatation, prolapse of the stomach and gastric neurosis."

The excesses or the deficiencies of products of the endocrine glands, producing manifestations of the ductless gland neurosis, passing through the blood stream, act directly on the muscle, causing pylorospasm, gastrospasm, hour-glass stomach or cardiospasm—various grades of atony. These excesses or deficiencies may also show their effects on minute limited areas of the muscularis mucosae or the mediums of the vessels producing the ischemia or stasis, either of these conditions leading to circulatory interference and altered nutrition. From these localized areas of ischemia or stasis, lesions occasionally form probably in the entire intestinal tract, as well as in the stomach and duodenum, but, on account of the absence of the hydrochloric acid, ulceration does not occur, at least with the characteristics of ulcus rotundum. These latter lesions may become the site of bacterial invasions, as in the appendix, for instance. The bacteria may become pathogenic and lead to a true appendicitis. Aschoff[13] and others do not believe in the bacteriologic origin of appendicitis, and, also, according to Hertogne,[14] appendicitis is due to thyroid insufficiency. Further, the frequent association of peptic ulcer, gastric or duodenal, with appendicitis, suggests that appendicitis is due also to an endocrinous origin.

That a neurosis precedes the ulcer is evident from reliable statistical data. Many authorities have compiled statistics and reports of cases in which neurosis preceded the ulcer. Cackovic[15] carefully analyzed histories of 172 cases of operatively demonstrated ulcer. In 18.5 per cent. of the patients, the initial symptoms appeared between the ages of 10 and 19 years; in 32 per cent., between the ages of 20 and 29 years; in 29 per cent., between the ages of 30 and 39 years, and in 18 per cent., after 40 years. The initial symptoms of ulcer are found in the third decade of life, at a time when neurosis is most frequent, but the operative evidence of the presence of an ulcer, however, is for obvious reasons obtained late in life.

Clinical observations prove that many patients afflicted with peptic ulcer present vegetative stigmata as evidence of the general neurosis. Peptic ulcer patients often respond to the pilocarpin test positively, or to the epinephrin test, or to both. Westphal and Katsch,[16] who have made an extensive study of the vegetative stigmata and who have completely enumerated all of them, found these stigmata to be absent only in the middle-aged; and these do not respond to either of the drugs. But signs of a disturbed equilibrium of the stomach, the signs of local gastric neurosis, are common in ulcer patients in all ages. They are hypermotility or spasticity, hypomotility or various grades of atony, and hyperchlorhydria, rarely hypochlorhydria, hypersecretion or hyposecretion. The hypertonic type of stomach and hyperchlorhydria are more often observed than the atonic type and hypochlorhydria.

Symptoms and signs of vagotonia or sympathicotonia or both, pointing to a general or local neurosis, are seen in the patients during the whole course of the disease and frequently persist after the patient has been considered medically or surgically cured. In a recently published paper,[17] it is shown why great value should not be placed on surgical, as well as medical, statistics concerning ulcer cures. The gastric neurosis ceases when the ductless gland neurosis has ceased, and this may often be accomplished by nature, assisted by medical or surgical procedures.

A ductless gland neurosis may, in the course of time, lead to actual pathologic changes within the gland itself, as happens to the islands of Langerhans from slight changes to their complete atrophy as in severe cases of diabetes, or as in the well known changes in exophthalmic goiter. This may explain the pathologic changes in the ductless gland found in patients afflicted with ulcer. The pathologist Cesaris Demel,[18] who investigated at necropsies the suprarenals in ulcer cases, found marked gross changes in the five examined.

Finzi,[19] in quoting him, suggests that in all necropsies of ulcer cases, the suprarenals should receive due investigation. Changes should also be looked for and noted in the thyroid.

RESULTS OF ANIMAL EXPERIMENTATION

The results of animal experimentation are also suggestive as to the probable endocrine origin of peptic ulcer. The acute ulcers in animals, produced in former experiments, heal rapidly. Panum and Conheim,[20] for instance, found ulcers with all their characteristics after injecting lead chromate into one of the gastric vessels arising from the splenic artery. Such animals, killed within a few days after the experiments, showed the typical acute ulcers, but all animals killed after the second week had a normal mucous membrane. The experimental ulcers heal because the constitutions of animals cannot be changed by experimentation.

Vagotonia, sympathicotonia, or a combination of both, are, according to Eppinger and Hess, constitutional anomalies. Experiments have been performed to alter the constitution in the animals, to imitate in a rather rough manner vagotonia and sympathicotonia in man. Lesions, erosions, or acute ulcers were produced by experimentally causing hyperfunction through injections of products of internal secretions, or by causing deficiencies in some of the ductless glands by partial or complete removal of the glands.

Acute ulcers in the stomach or duodenum, or in both, were obtained after complete or partial removal of the suprarenals by Finzi and myself[21] in dogs and rabbits, by Elliot,[22] in cats, and by Mann[23] in dogs. After partial parathyroidectomy, Carlson and Jacobson[24] observed acute ulcers in the stomach and duodenum of dogs, and I observed them in dogs and rabbits. After repeated injections of desiccated thyroid extract, gastric ulcers were noted in dogs and rabbits, and after repeated epinephrin injections, lesions or acute duodenal ulcers were observed in dogs and, occasionally, in rabbits. Peptic ulcers were obtained by Westphal[25] after pilocarpin injections in rabbits, dogs and cats. I found gastric ulcers after such injections in rabbits, and gastric and duodenal ulcers or lesions, after injecting into rabbits, pilocarpin and epinephrin alternately.

Pilocarpin closely resembles thyroid extract in its action. Injections of thyroid extract in animals lead to profuse diarrhea, similar to the action of pilocarpin injections. The effect of pilocarpin is greatly reduced in thyroidectomized animals. By feeding animals or man with thyroid extract, one obtains results which resemble greatly the pharmacologic action on the administration of pilocarpin: diarrhea, perspiration, respiratory disturbances, lymphocytosis and eosinophilia. The cells of the thyroid, according to Wyss and Schafer,[26] react to pilocarpin in the same way as the cells of the true secretory glands.

In all the experiments, the lesions or ulcers obtained were often single. In none of the animals were there the characteristics of chronic ulcer noted in man, but the tendency against healing was often evident. This was especially noted in our[27] animals in which an ulcer was found several months after the parathyroidectomy was performed. Finzi also emphasizes this lack of healing power after partial suprarenalectomy. That the ulcers obtained in all the animals were really due to an intentional disturbance in the glands, is clear from the fact that in rabbits in which epinephrin was injected or suprarenals implanted (Finzi), after removal of the suprarenals, the mucous membrane of the stomach was found to be intact, the same as the mucosa of the animals used as controls.

As the main purpose of all the experiments in which the endocrine glands were removed or the products of these glands injected was to imitate the constitutional anomalies found in man, such experiments, I believe, are of greater value than those hitherto described. These experiments are especially of great interest and benefit because they demonstrate the possible relation of the lesions or ulcers to a disturbed motility.

The animals, which received repeated injections of thyroid extract for several weeks, suffered from diarrhea, practically after the second injection, and similarly profuse diarrhea was a conspicuous feature in those injected with pilocarpin. The dogs, however, were obstinately constipated on repeated epinephrin injections, during the period of the injections. Constipation was not a prominent feature in rabbits which were injected alternately with pilocarpin and epinephrin. In the rabbits injected with pilocarpin alone, in which a necropsy was done soon after the last injection, the stomach frequently presented the various stages of spasticity, that is, pylorospasm, gastrospasm, hour-glass stomach and even cardiospasm. In the animal at necropsy several months after the thyroidectomy, the stomach was often markedly dilated without the presence of any obstruction. The stomach resembled greatly the atonic stomach observed under the fluoroscopic screen in ulcer cases. On histologic examination, sections of the stomach showed fatty infiltration or fatty degeneration in the gastric musculature, especially near or at the pylorus.

One must assume that this infiltration is similar to that observed in the musculature of the tongue and skin in myxedematous patients. Pilocarpin produces irritative conditions in the vagus, resulting in spastic stomach and in increased intestinal peristalsis, and also contracts, according to Pal,[28] the mesenteric vessels. Injections of thyroid extract must have a similar effect, namely, diarrhea and spastic contraction of the stomach. The spastic stomach is also observed clinically by fluoroscopy in exophthalmic goiter cases with severe gastro-intestinal disturbances. Irritative states in the

vagus must exist, as it was explained, in the animals, after partial or complete suprarenalectomy, or after parathyroidectomy, for peptic ulcer cases with tetany and pylorospasm have been observed. Thyroid deficiencies, caused by thyroidectomy, produce hypotonic conditions due to diminished vagal stimulation. Epinephrin injections, as in experimental suprarenalemia, produce hypotonic conditions, due to increased inhibition of the splanchnic nerves.

Therefore, the hypertonic stomach, or the subtonic stomach, in which the presence of an ulcer may be demonstrated, is attributed primarily to a disturbance in the thyroid or in the suprarenals. If the effect is on minute localized areas of the organ, ischemia or stasis, as explained, results. The initial lesion of ulcer gradually develops and through the secondary factors mentioned, the typical ulcer is produced.

CONCLUSIONS

1. The initial lesion of the peptic ulcer is due to vascular changes, such as ischemia or stasis, attributed to contraction or dilatation of limited areas of musculature either of the vessel itself or of the muscularis mucosae surrounding that vessel.
2. The spastic or subtonic stomach of gastric neurosis may lead to these vascular changes. The spastic stomach is caused by deficiencies in parathyroid or epinephrin secretions, or, by excesses of one or more of the thyroid products. The subtonic stomach is due to deficiencies in thyroid products or to excesses in parathyroid or epinephrin secretion.
3. The altered peristalsis in peptic ulcer is produced chiefly by glandular neurosis, either in thyroid suprarenals or parathyroids.
4. The ductless gland neurosis causes secretory disturbances either directly or indirectly, by centering its influence on the pyloric or duodenal mucosae, endowed with endocrine properties.
5. The functional disturbances in the true endocrine glands may, in the course of time, lead to actual pathologic changes in themselves.
6. Acute experimental ulcer after partial parathyroidectomy of partial suprarenalectomy does not show a tendency to heal.
7. The spastic stomach may frequently be produced experimentally by injections of pilocarpin, whose pharmacologic action is similar to that of thyroid extract.
8. Atonic dilatation is observed after partial thyroidectomy.
9. Hydrochloric acid is an important factor in the further development of the acute ulcer from the initial lesion.
10. Clinical observations in conjunction with experimental findings suggest the endocrine origin of the initial lesion of peptic ulcer.

ABSTRACT OF DISCUSSION

Dr. Frank C. Mann, Rochester, Minn.: There is no doubt that the chronic ulcer must have an acute beginning. It is a different question, however, whether or not acute ulcers, from all causes, or from only one or two particular causes, develop into the chronic ulcer as it is seen in man. The relationship of the ductless glands to the production of ulcer is certainly closely associated with the relationship of the nervous system to the production of this lesion. Acute ulcers are quite easily produced by a score or more of methods. My work is in entire accord with the experimental work of Dr. Friedman. It is a different problem, however, to produce the chronic indurated type of ulcer. In a series of about 200 experiments, in which I removed only one suprarenal, only one chronic ulcer was produced. Extirpation of both suprarenals probably produces ulcer in 95 per cent. of the cases. The part a toxic condition plays in the production of chronic ulcer is not clear. I have received communications from a large number of laboratories, both in this country and abroad, stating that in their work in Pasteur institutes, or in studies of diphtheria toxin, they found that the injection of the toxin produced a double lesion, one in the suprarenals, and one of the mucosa of the stomach (the acute ulcer), and they felt that there was a relationship between the two. I believe it would be very difficult to tell whether the two were dependent on each other, or both dependent on the toxic condition. I am inclined to believe that if we have any severe toxic state, we have the elements for the formation of acute ulcer, and that a chronic ulcer will develop on any of these.

In a small series of cases of Addison's diseases in which I witnessed the necropsy, I have found only one case in which there was a chronic ulcer. In this case there also were a small number of acute ulcers. Certainly, in the formation of these acute ulcers we have two things: first, something in regard to the relationship of the anatomic mechanism of the gastric mucosa and its adjacent muscularis, together with some toxic factor which changes the condition of the cell, and the digestion of the gastric juice. For instance, in these ulcers which follow conditions like double suprarenalectomy, you will not get ulcers if a portion of the lower intestine is implanted into the stomach; in other words, the mucosa of the implanted jejunum will remain normal, although ulcers may occur around the stomach, showing that there is some definite condition in the mechanism of the mucosa of the stomach. And the same fact is true of the upper portion of the duodenum.

Dr. V. A. Lapenta, Indianapolis: We have too great a tendency to crystallize our views of these chronic lesions to infections solely. I believe that it can be stated by all men who have had more or less experience with these lesions, that such patients unmistakably exhibit either a type of vagotonia or sympathicotonia, I have never seen a patient with either acute or chronic ulcer, and especially chronic ulcer, who was not either a vagotonic or sympathicotonic individual. I do not believe that Dr. Rosenow's work disputes Dr. Friedman's findings. In fact, his work in the production of gastric and duodenal ulcer, with special strains of streptococci, by him isolated, is rather corroborative, because in the intravenous injection or parenteral injection of such toxins and proteins, with their peculiar atomic structures, there is caused a disturbance of the suprarenal system, with resultant sympathicotonia or vagotonia. This is the first step in the suprarenalogic reaction in the molecular processes. The bacteria find in the devitalized piece of gastric mucosa a most suitable place to localize, and ulcer is produced. Dr. Rosenow's work really brings experimental evidence to Dr. Friedman's contention. We must bear in mind another thing: Peptic ulcer is a disease of civilization. You never saw peptic ulcer in imbeciles; it is mostly a disease of very nervous individuals; it is a disease of civilization.

This seems to emphasize the question of the energy intake and the energy output, and the rôle played in the equilibrium by the suprarenal system. In the modern conception the high kinetic drive, the insult to the vasomotor balance that is brought about by these nervous emotions will in the course of time, naturally not months or days, lead to localized angioneurosis, which when present in the gastric mucosa, may result in peptic ulcer.

Several years ago it was pointed out that once an area of decreased resistance is formed in the stomach, gastric juice corrosion will do the rest, and if there are foci of infection, then you have a true cycle, and you are going to have an ulcer, and in nine cases out of ten that ulcer will become chronic. I believe that Dr. Friedman showed very active round cell infiltration in his specimens. This is very suggestive of the final result.

Dr. Bertram W. Sippy, Chicago: For half a century it has been generally recognized that ulcer of the stomach or duodenum develops in approximately the following manner: A small, circumscribed or local area in the mucous membrane of the stomach or duodenum for some reason loses its normal resistance to the peptic action of the juices and becomes digested. This resistance to the normal condition of the peptic action of the gastric juice was first supposed to have been brought about by malnutrition or necrosis. In 1855 Malnckow pointed out that it was a vascular condition of some kind that had to do with the interference of the normal resistance, this corrosive action of the gastric juice. From that time on a large amount of experimental work has been done. Injection of lead salts has tended to prove that if you interfere with the nutrition of the mucosa of the stomach or duodenum a peptic ulcer will result. A large number of means have been used to produce the peptic ulcer, or the ulcer in the stomach or duodenum, but all of them, so far as we can make out, have to do either with spasm or the introduction of some toxic substance, of bacteria, of a ligature or something that interferes with the nutrition of the mucosa. The arteries of the stomach are end arteries entirely; that is, they have very few anastomoses. These experimental ulcers, produced in that way, heal rapidly, relatively speaking. The reason was thought to be, and probably is, that a raw spot is not an ulcer. There is a difference between these experimental ulcers and the clinical ulcers. This experimental ulcer destroys the mucosa. The base of this ulcer may have nothing in it to cause it to lose its normal resistance to the peptic action of the gastric juice, and under such conditions that raw spot will heal just as well in the presence of hydrochloric acid and pepsin as it would if there were no hydrochloric acid and pepsin there. Nothing interferes with the blood supply to that part. In these chronic ulcers, those that do not get well, it is assumed that the tissue had lost its resistance to the peptic action of the gastric juice, and therefore the hydrochloric acid and pepsin would keep it from healing. It is possible that the bacteria in the walls of this ulcer have something to do with lessening the resistance of the tissue to the peptic action of the gastric juices. Corrosion of the gastric juice is the most important factor.

Dr. Martin E. Rehfuss, Philadelphia: About ten years ago Dr. Leo Loeb and I were engaged in the study of the experimental production of gastric ulcer. We found that we could administer to animals the venom of *Heloderma suspectum*, a form of venomous lizard obtained in New Mexico, and in that way produce an acute ulcer. We injected alkali into the stomach of these animals and found that this alkali reduced the possibility to ulcer formation. We gave the animals herudin. In several instances the animals bled to death in their own stomachs. We then tried other substances, or caused acute toxemia in the animal, tried pilocarpin and atropin, which are supposed to act on the vagotonic system. We tried the effect of hydrochloric acid, phenol, copper sulphate and bacterial toxins. We found that every variety of substance produced an acute ulcer lesion of the stomach; it was something of a hemorrhagic lesion.

I saw some of the animals that Dr. Rosenow used in his experiments, and the lesions which he showed at that time were just the same sort as we succeeded in producing with various toxic substances. Shortly after that I went to Paris to the Pasteur Institute. I collected the stomachs of a very large number of laboratory animals dead of various bacterial infections. It is possible to produce a form of ulceration with almost every toxic substance if you can get the animal in a sufficiently high state of toxicity. In other words, it is my belief, from the experiments we performed, that there is a form of ulcer which is not specific. Whether or not these ulcers become chronic, whether they resemble the chronic ulcer seen in man, I am not prepared to state; but one thing is certain, an acute ulcer, an acute corrosion, can be produced in a great variety of ways. If that be the case, what is the theory we should adopt? The experiments of Rosenow are most convincing. I have adopted the plan in all cases of ulcer treatment to administer at the same time an autogenous vaccine prepared from local foci in the nose, throat, teeth, etc. What that has done I do not know. I have not yet collected the statistics. In almost every instance it is possible to extract a form of streptococcus from the nose, teeth or throat; and in quite a few instances I have given the stock vaccines and the combined colon bacillus.

Bolton produced localized erosions and ulcer with gastrotoxic serums, and our photographs record that our ulcers are the same, or the areas, the small ulcers, the same as he has shown in his book.

Dr. G. A. Friedman, New York: I was misunderstood by the majority of those who took part in the discussion. My object was not solely to demonstrate experimental ulcers. We know that ulcers may be produced experimentally by various means. I explained in my paper that a condition such as ductless gland neurosis is possible, and that the latter causes the gastric neurosis which leads to spasticity or atony of the stomach. This spasticity or atony may show its effect on small gastric vessels, and in this way the initial lesion of ulcer may take place. I do not know the cause of chronic ulcer. I should first like to know the cause of acute ulcer. My object was to study the latter from a new view point, and it seems that the explanation given here brings the clinical work in close association with the experimental work, which connecting link was, I believe, overlooked by the gentlemen, except Dr. Lapenta.

I have never found chronic ulcer in any of my experiments, but I have observed ulcers without the tendency to heal in animals after parathyroidectomy. The ulcers were frequently found several months after the operations were performed. Similar observations regarding the failure to heal after parathyroidectomy were made by Finzi, an Italian investigator. Since acute ulcers produced by other means heal rapidly, the absence of healing power in the aforesaid experiments prove that constitutional anomalies can be imitated roughly in animals, and that the constitutional changes in man afflicted with ulcer prevent the ulcers from healing. From my experience with infectious diseases and oral sepsis in Russia I have not gained the impression that ulcer is commonly caused by infection. The infectious theory explains only one phase of the ulcer, while the explanation outlined here today covers several phases. Naturally the material which I have presented is not yet complete. I have presented this paper simply to stimulate others to continue this work.

Health Organization and Administration in Rural Districts. —If I were asked the question: "What one step would be of the most importance in the final creation of an adequate public health organization and administration in rural districts?" I should say—the creation of a public health consciousness in rural districts through the education of country boys and girls. If I had my way, I would take Professor Sedgwick from the faculty of the Massachusetts Agricultural College at Amherst and require him to teach public health and biology as a regularly prescribed course; and I would make it sufficiently attractive for Dr. Rosenau to resign his position at the Harvard Medical School and accept a like position on the agricultural school faculty at the University of Maine. In other words, I would appoint on all the agricultural school faculties throughout the United States first-class experts and teachers to teach the subjects of preventive medicine and public health as required courses, and to supervise extension work in these subjects. I would expect the agricultural school boy who is to return to the country life to learn as much about the human body and its diseases, and the methods of public sanitation, as he or she learns about the care and breeding of hogs, the raising of corn and wheat, and the scientific fertilization of the soil. These leaders would return to their respective home communities and plant the necessary seeds which would result in a ripe harvest of public health opinion and adequate organization and administration in rural districts. Furthermore, matters pertaining to personal and public health should be taught to the rural population in general through the agency of the extension divisions of our universities. It is high time for less discussion in Boston and other cities of rural health administration, and for more discussion in Podunk and other country communities of rural health problems and administration!—L. D. Bristol, State Health Commissioner of Maine, *Bulletin*, State Department of Health, August, 1918.

MICROSCOPIC STUDIES OF DISEASED PERIDENTAL TISSUES *

EDWARD H. HATTON, M.D.
CHICAGO

Most of the material on which these studies are based came from the peridental membrane clinic at the Northwestern University Dental School. In all of these, therefore, there are alterations of a high degree. At the same time, there are portions of each fragment that are only moderately changed. Zenker's fluid was used most often for fixation, and either celloidin or paraffin used for embedding. Paraffin was finally selected as the routine procedure because it was possible to get thinner sections and serial sections were more readily obtained. Hematoxylin and eosin, or methylene blue and eosin were the chief stains used. Occasionally methylene blue was used alone. The serial section procedure has more than paid for the trouble it entails, as it is only in this manner that the changes can be followed straight through the block, and reconstructions of the various parts achieved. An especially good illustration of this is in the transitions that take place in the epithelial layers.

These studies were begun as a routine procedure on all pieces of the gingivae removed to give deep pockets in the subgingival space a better chance to be obliterated, with the idea of seeing just how much destruction of the essential structures had taken place. The studies are confined to a rather superficial portion of the soft tissues investing the teeth, and no pretense is made at this time to present them in any definite relationship to etiologic factors, or to suggest a classification. There seems to be a very definite and constant picture presented in each specimen, only the details varying either as to extent, or as to the circumstances of their origin, which are apparently the result of etiologic factors.

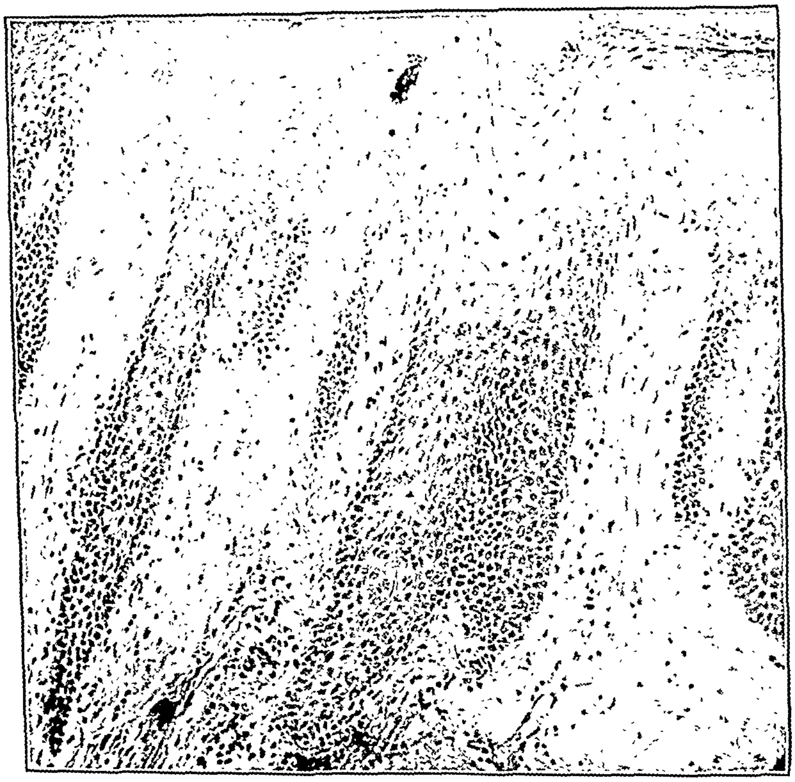

Fig. 1.—Elongated epithelial projections into the underlying tissues with accompanying round cell infiltration.

ALTERATIONS IN THE EPITHELIUM

Of all the changes, none are more picturesque than those occurring in the epithelial layers clothing the gingivae of these specimens. With one exception, they are probably not of vital importance, but they deserve description for two reasons, first, because they are part of the picture, and second, because there is a strong possibility of their being confused with other conditions.

An early alteration is the tendency of the epithelial projections into the subepithelial layers to extend themselves and so exaggerate the length of the papillae. A close examination of these projections will always reveal regions of infiltration along the basement membrane in the adjacent tissues, usually of the small round cell or lymphocyte type. These projections are slender, and as the condition advances, they twist and turn so that sections cut at any angle always have rounded, oval, or cylindrical masses of epithelium which seem unattached to any of the surface epithelium. By studying these in serial sections, we find it always possible to join them to projecting epithelial pegs. Such deformities of the epithelium are frequently found on the surfaces lying outside of the subgingival space, but they are rarely of any greater extent. It is a chronic or low grade inflammatory process.

But the epithelium, which lines the so-called pus pockets and which formerly was adjacent to the teeth, is always the site of other very noteworthy alterations. As this trough widens and deepens there is a tendency for the epithelium to project itself farther into the subepithelial tissues, and the forms of these projections become progressively more and more chaotic, the deeper they lie in the pocket. At the bottom, the surface continuity is no longer maintained in every case, but there are still masses of epithelial cells at the very bottom of every pocket examined thus far. These cords and projections are the seat of retrograde, disintegrating changes that begin at their centers. It is assumed that the older epithelial cells are less resistant to the destructive agents than are the new cells. Fragmentation of their nuclei, necrosis, infiltration with polymorphonuclear leukocytes, and other inflammatory cells all take place in a regular sequence, so that as an end-result the cylindric, ovoid, or spherical bodies become thin shells whose walls are composed of very new epithelial cells, and whose contents are more or less purulent fluid or semisolid material.

From the character of the epithelial cells, that is, their age, and their rapid destruction, these regions must be very unstable. The cells are small, with small nuclei which take the blue nuclear stains very deeply. They resemble the cells ordinarily found in the base-

ment membrane. It is easy to assume that these epithelial cells exhibit a negative chemotaxis to the products of this process in the gingival trough, and that they push down into the subepithelial layers stressed by this force. Small blood vessels are found in these regions in great numbers. They are frequently packed with polymorphonuclear leukocytes, and nearly always contain one or several of these cells. Red cells are often found in considerable numbers outside the blood vessels, even to the extent of small hemorrhages. These may be the result of surgical trauma. The cells are often separated as though by fluid. Possibly this is caused by an edema or it may be simply an artefact. All these products are being constantly extended into the subgingival space, which, as a result, becomes a pus pocket. To one not familiar with this type of inflammatory tissue, some of these malformations are strongly suggestive of malignancy. There is apparently no relation at all between the two conditions.

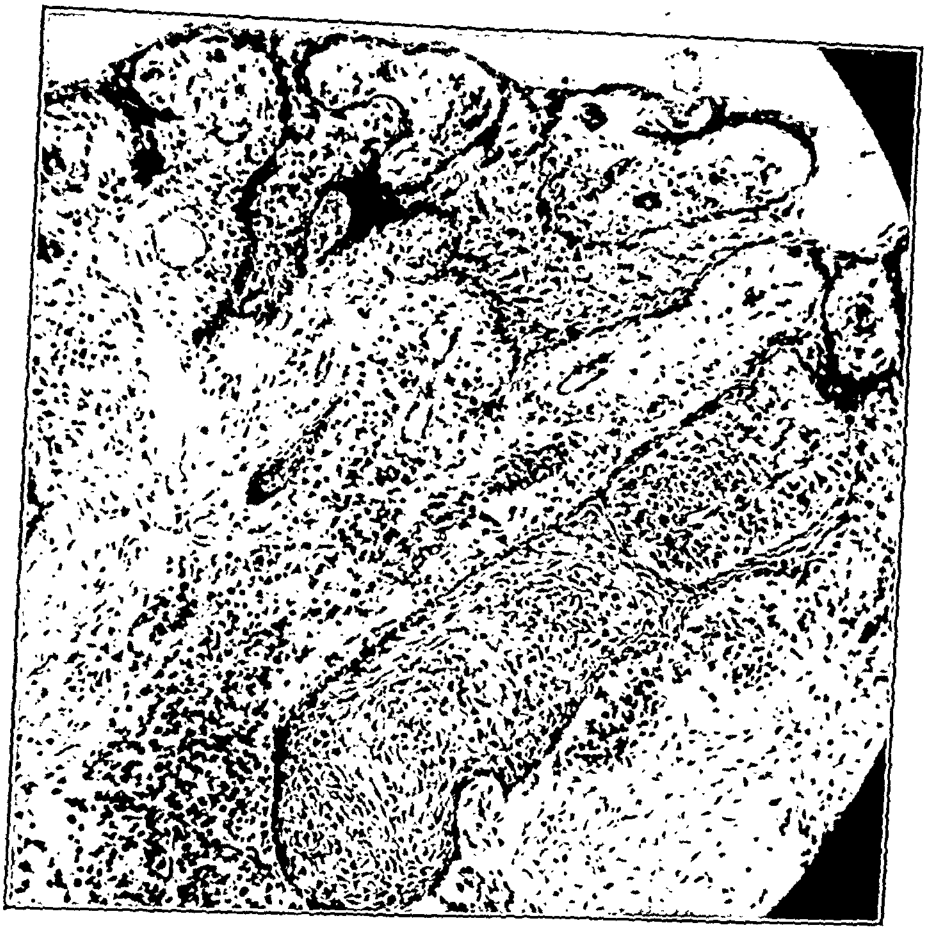

Fig. 2.—Epithelial deformities of the mucous membrane lying within the lining of the pus pocket.

INFILTRATIONS

The subepithelial regions as far as studied are characterized by inflammatory infiltrations which are invariably perivascular. Their distribution is most conveniently seen in buccolingual sections parallel to the long axis of the teeth. If the capillaries that supply the papillae just beneath the deformed and distorted epithelium are traced down into the deeper layers and their course followed even into the larger branches, just these and no others are the site of these infiltrations. In some sections, this border between healthy and infiltrated regions is most abrupt.

The infiltrating cells are most often of the small round cell type. There are large numbers of cells called plasma cells, with deeply stained cytoplasm and eccentrically placed nuclei. Occasional eosinophil cells are found, and polymorphonuclear leukocytes are not uncommon, especially in parts adjacent to degenerated epithelial projections. Unattached endothelial cells are frequently seen.

The vascular supply is very rich. The walls of the small veins and capillaries are often thickened, and many of these vessels are filled with polymorphonuclear leukocytes to the exclusion of the red cells.

The fibers of the gingivae and of the peridental membrane seem to be very susceptible to the destructive action of these forces. One of the first tendencies is for the fibers to lose their affinity for the stains, and either stain more faintly or react with the nuclear stains. Little by little, the fibers are replaced by the inflammatory infiltration. There are regions about the size of these epithelial ovoids which no longer have any cellular structure, and are occupied by a homogeneous staining substance. This seems to be some product of degeneration, either of dead epithelial cells or from some other necrotic process.

If a buccolingual section is carefully studied as to its form and the relations of its various parts, it will be found that a large portion of the free gingiva has disappeared. There is nearly always a mass of necrotic material lying on the epithelium at this point or just within the inner lip of the pocket. If the surface of the adjacent tooth is approximated, and the curve of the outer surface of the gingiva projected until it intersects with the buccal surface of its tooth, the amount of destruction may be very accurately estimated. There is a very marked tendency of the new crest to lie near a straight line drawn from the bottom of the pocket or the subgingival space to the nearest unaltered epithelium. If a line is drawn from the last point parallel to the distribution of the ascending capillaries down to the alveolar process, this line will mark the division between the healthy peridental membrane and the region in which there is inflammatory infiltration and destruction of the fibers of it. In the latter region, the infiltration is usually so marked as to assure the nearly complete destruction of the fibers, and in these advanced cases which are here described, there is no tendency to any reconstruction of them. As far as these tissues are concerned, when once the fibers are destroyed, they do not seem to be regenerated.

BACTERIA IN THE TISSUES

Bacteria have been demonstrated in various tissues by the newer methods of bacteriology, as well as by the more standard staining processes. Tubercle bacilli are often found in the tissues, as well as typhoid, plague, and the spirochete of syphilis in the lesions which they respectively produce.

More recently cocci have been demonstrated in the tissues during the course of various diseases, such as poliomyelitis and experimental scurvy. Curtis[1] found cocci in uteri removed for various causes, and Rosenow[2] has described an infected root apex about which there was a small region of granulation tissue, in which he was able to demonstrate a latent group of bacteria, which were stimulated to growth by incubation in bouillon for ten hours. Then the tissue was fixed, sectioned and stained.

---

[1] Curtis, A. H.: Bacteria in the Uterus, Surg., Gynec. and Obst., 1918, 26, 178.

In spite of the fact that recent work has shown that bacteria invade the blood stream comparatively frequently in many conditions, yet it seems that there must be an easier way for bacteria to reach the peridental membrane and the apical region of the teeth, or even the pulp cavity, than by the blood stream. All these results, as well as the peculiar pathology of the regions about the vessels, stimulated a belief that bacteria could be found in these diseased gingivae.

Cultural methods were tried at first, but the pieces of tissue were so small that, by the time the external surfaces were sterilized by heat or hot oil, there was always a suspicion that the bacteria inside had been destroyed at the same time, that is, granting that they were there, or on the other hand, that contamination from the outside had not been ruled out.

Thus far, bacteria have not been found in any large number of cases, and no attempt has been made to arrive at any conclusions as to the frequency with which they are found. The forms resemble those of the streptococci that have been found quite constantly in the pus pockets. For the great part, they lie about the vessels which are surrounded by the cell infiltrations already described, and are more frequently disclosed near the bottom of the pocket. They may be in small masses, or in groups of two, four, six or eight.

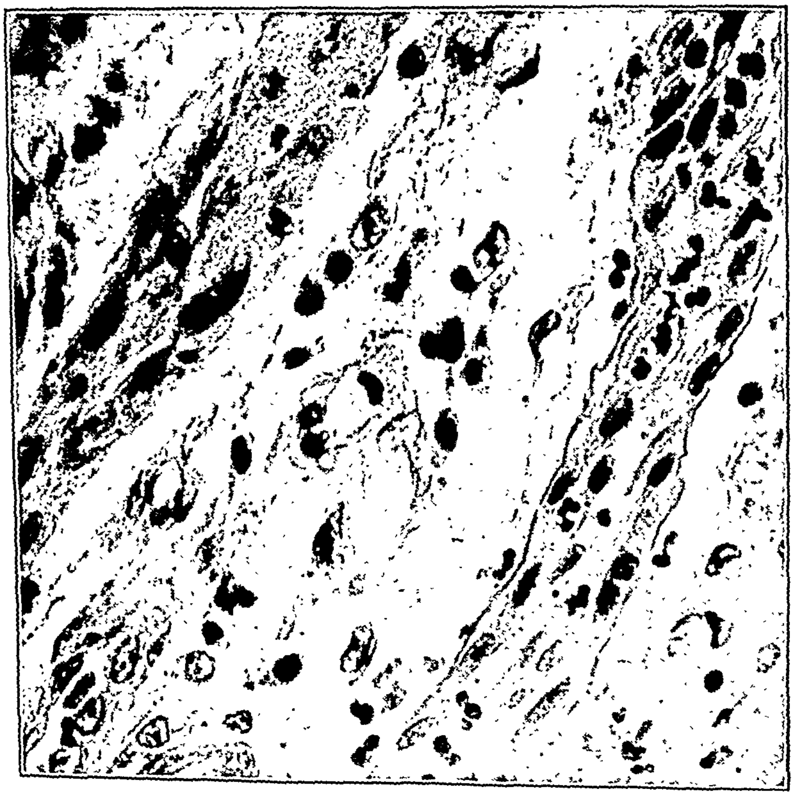

Fig. 3.—Polymorphonuclear leukocytes in the epithelial projections and the intervening spaces.

Their relation to the surrounding pathologic changes, or their ability to penetrate farther into the peridental membrane or down to the apical region, is conjecture and a subject for further investigation.

There is a very striking analogy between the location and the distribution of the lesions described in the foregoing and the distribution of the dental lymphatics, as demonstrated by Noyes[3] and Schweitzer.[4] It is known that the lymphatic vessels play an important part in the distribution of infection elsewhere in the body. With their demonstration in the peridental membrane as well as the pulp in a way that seems beyond equivocation, their importance from the standpoint of the part they play in the pathology of the tissues can hardly be overestimated. The distribution of these pathologic changes here described seems compatible only with the notion that they exactly parallel the distribution of the lymphatics in the same region. It answers the question why the line of progress is always downward and inward, why with a broad shelf-like erosion, as occurs under a salivary calculus, there is a broad band of infiltration, and why there is such an exact and abrupt division between the regions of infiltration and those free and uninvolved.

31 West Lake Street.

ABSTRACT OF DISCUSSION

Dr. Arthur D. Black, Chicago: Those who have studied the work which Dr. Noyes has reported to this section during the past two years will recognize the important relationship between his studies of the normal tissues, demonstrating the lymphatic channels in the peridental membrane, and Dr. Hatton's studies of the pathologic changes in this membrane. They corroborate each other, and both fit in with the most careful clinical observations of the progress of these infections. I would like to emphasize the difference, observed clinically, in the progressive destruction of tissue in the case of the pus pocket, beginning in the gingival line of the tooth, and of the chronic alveolar abscess, beginning at the apex of the root. In the one beginning at the gingival line we have noted the tendency to progress most rapidly toward the apex, forming a deep, narrow pocket, while in the alveolar abscess there has not been the same tendency to progress crownwise. Dr. G. V. Black referred to this as early as 1886, and in his recent book on Dental Pathology there is a paragraph calling attention to the fact that we must have a proper explanation of the difference in the progress of these two types of infection involving the same tissue. If the route of travel is by perivascular lymphatics, the clinical observations in both conditions are explained, because the flow of lymph is from the gingivae toward the apex, which would promote the progress of infection toward the apex in the case beginning as gingivitis and retard a similar progress crownwise in the case of the alveolar abscess.

The study of the movements of the ephithelium is very interesting, especially the apparent effort of the epithelium to line the pockets about the sides of the roots. It is possible that in a small percentage of cases pockets along the sides of the roots have been lined by epithelium, and the individuals have thereby been protected from systemic infection. In treating these cases by cutting away the tissues which overlie the surface of the roots, there occurs a rapid growth of epithelium over the cut surface down to the line of attachment of the root. All of the studies of the tissue changes support this plan of treatment as being the most practical method of eliminating the menace to the general health.

Dr. Eugene S. Talbot, Chicago: The most interesting part of this paper is the migration of the epithelial cells. These cells will migrate almost anywhere when they get started. The question naturally arises, How far will they extend into other tissues and how far will they extend down through the peridental membrane? My research of these subjects leads me to believe that very little work has been done on the migration of epithelial cells. I think Dr. Hatton will agree with me that it will be impossible for these cells to migrate through bony tissue. All his pictures showed that they are located in soft tissues, so we will have to set down as a fixed point that they cannot migrate through bony tissue.

The next question to settle is, How far will these epithelial cells migrate from the surface down into the soft tissues. My studies showed conclusively that the cells of the external epithelium do extend into the fibrous sac or peridental membrane, or far down to the ends of the roots of the teeth, before the bone begins to form. We have all seen epithelial cells in the peridental membrane at the root of the tooth. Another point that I did settle the other day conclusively and which has been attacked by eminent men is that these epithelial cells migrate into the fibrous sac from the external epithelium. Dr. Hatton and Dr. Black both mentioned the fact in regard to the lymphatics that these cells have a tendency to migrate downward. There is no question about that. In the last four or five years I have been doing extensive operations on dogs by using all the drugs that we use on our patients. You would be surprised to see the effects of these drugs and the absorption that has taken place by the use of a simple alkaline mouth wash by producing an irritation through the end of the root into these tissues, and I have many photographs which show this absorption and then the inflammation and abscess formation between the roots of the molars and also abscesses along the margin of the gum tissue. These experiments showed conclusively that by forcing an irritant through the end of the root an inflammation is set up and an abscess forms, not at the end of the root, but higher up between the roots of the molars and the gum margin.

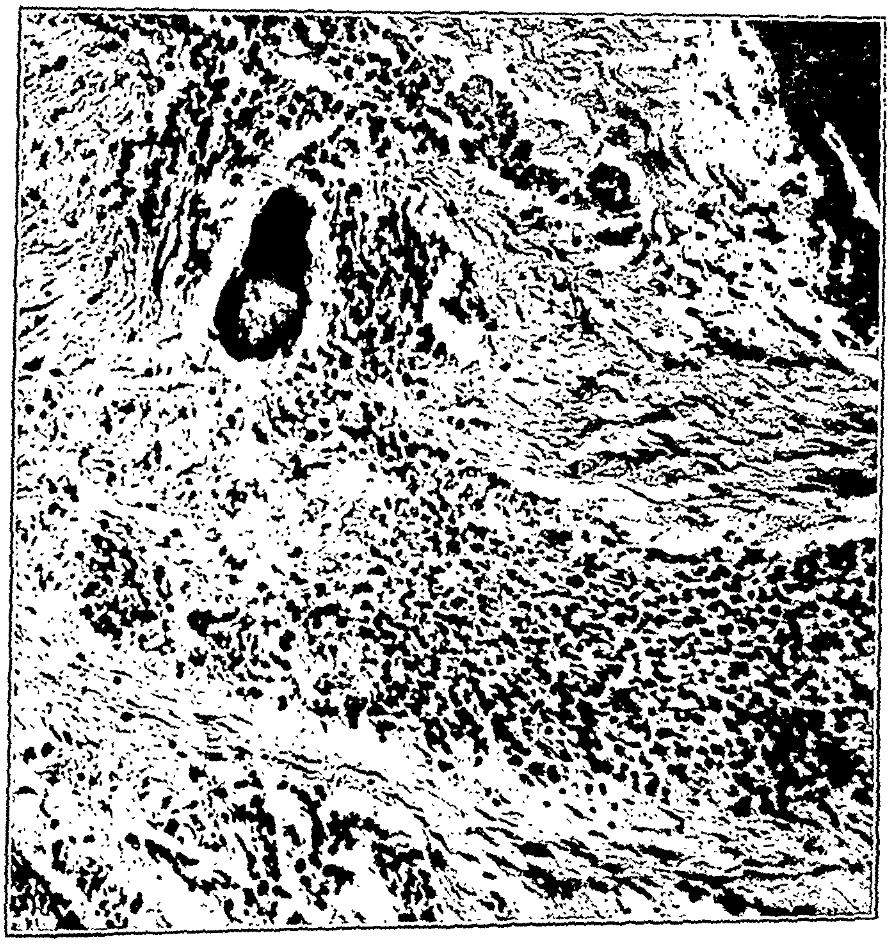

Fig. 4.—Perivascular round cell infiltration of the gingivae with destruction of the fibers of the peridental membrane.

Dr. V. H. Moon, Indianapolis: One or two points of Dr. Hatton's presentation coincide with our experience in the pathology of other tissues; namely, the thinning out and disappearance of fibrous tissue in connection with an acute inflammatory reaction. This phenomenon is found elsewhere, and it may be explained as being due to a proteolytic ferment which is produced by the inflammatory cells, which have the function or capacity for absorbing fibrous tissue. So, in pus formation, where there is actual destruction of tissue, the liquefaction of the tissue is due, in part, to the proteolytic ferment produced by the cells which infiltrate that region.

As to the migration of epithelial cells, we have learned in other lines of pathology to be conservative in our statements for the reason that the wandering cells of the body, which are found in almost every tissue, so closely simulate epithelial cells in their characteristics that it is difficult to decide whether we are looking at an epithelial cell or at one of these wandering cells. These wandering cells are very common in regions which are subject to chronic infection.

Usually when the fibrous tissue is disappearing as a result of inflammatory reaction, hyaline degeneration occurs, the tissue taking a homogeneous, rather deep pink stain. I have not noticed change of staining to a basic character except occasionally in tuberculosis and syphilis. After the fusing together and hyaline degeneration of the fibers there is a subsequent liquefaction, and the liquefied tissue and inflammatory cells are carried off by the lymphatics.

I did not wish to be misunderstood as referring to the true proliferation of epithelium to cover a granulating wound surface, which is a regular occurrence on all surfaces that are covered by epithelium. What I referred to was the migration through the tissues of epithelial cells. Epithelial cells will grow very readily from an adjacent epithelial surface. It can be demonstrated in connective tissue cultures in the test tube that as the fibrous tissue proliferates and grows the epithelial cells which are in culture with it will grow and spread along the surface of those fibrous tissue cells. The same thing occurs in the healing of wounds or in any wounds or granulating surface adjacent to the epithelial covering.

Dr. Frederick B. Moorehead, Chicago: The differentiation between epithelial cells and epithelioid cells, as Dr. Moon has just suggested, is very important. The proliferation of epithelial cells in continuity, as seen in skin grafting and in the repair of surface wounds, is well illustrated in clinical surgery. I see no reason why the surface epithelium should not grow into the pockets, even to a considerable depth, in the cases Dr. Hatton cited. I believe it will be seen that it is more a question of proliferation by continuity than by cell migration that these spaces are lined by epithelium. In pyorrhea pockets, so called, where the infection has been controlled, the conditions of heat and moisture are present and there is also enough mechanical irritation to stimulate the proliferation of epithelial cells. Moreover, there is always a tendency of epithelial cells to repair and cover defects.

Dr. Edward H. Hatton, Chicago: The possibility of the migration of epithelial cells has been explained by the other speakers. I believe that in all my specimens those projections are true epithelial cells, because I think that in every case, by means of serial paraffin sections, I am able to demonstrate that they are. I cannot say that I have found any true epithelial migration, except the growth into fluids.

OSTEOMA OF THE FRONTAL SINUS

W. W. BOARDMAN, M.D.

AND

MARY M. DONOVAN, M.D.

Associate Professor of Medicine and Assistant in Medicine, Respectively, Leland Stanford Junior University School of Medicine

SAN FRANCISCO

The occurrence of osteoma of the frontal sinus is relatively infrequent, as may be judged from the fact that Sewall,[1] after carefully reviewing the literature, found only ninety-two cases. In these cases the diagnosis was based on the presence of anatomic deformities secondary to the osteoma; in only a few had the roentgen ray been used to confirm the clinical impression, and in none had the condition been primarily diagnosed roentgenographically.

During the past six months the following two cases of clinically unsuspected osteoma of the frontal sinus have been discovered in the routine examination of skull plates.

Case 1.—A man entered the Stanford University Medical School Hospital, complaining of very severe headaches of long duration. In the early stages these had been frontal, but of late they had been principally occipital. Diffuse brain tumor seemed to be the clinical diagnosis. However, lateral stereoscopic skull plates showed an abnormal area of density in the region of the frontal sinus. Examination of sinus plates showed a uniformly dense, sharply outlined shadow in the right frontal sinus. On these findings a diagnosis of osteoma of the frontal sinus was made. At operation a hard, bony tumor was found firmly wedged into the sinus. It was successfully removed and the patient has been completely relieved of all symptoms.

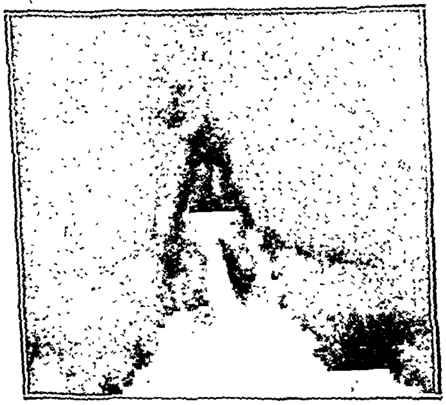

Fig. 1 (Case 1).—Anteroposterior view of osteoma of frontal sinus. The tumor occupies the right frontal sinus, although not completely filling it.

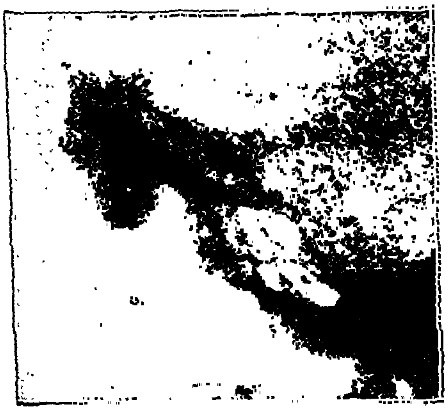

Fig. 2 (Case 2).—Lateral view of osteoma of frontal sinus. The tumor apparently does not quite fill the frontal sinus but extends downward into the ethmoid region. Its irregular shape is striking.

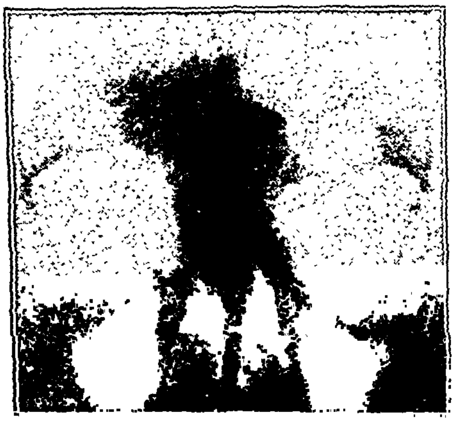

Fig. 3 (Case 2).—Anteroposterior view of same case. The tumor appears to involve one of the frontal sinuses more than the other. Its invasion of the ethmoid region shows plainly.

Case 2.—A young man came complaining of convulsive attacks, simulating epilepsy, but with no objective deformities suggesting osteoma. Examination of plates of the skull showed a large, dense, irregular shadow occupying the frontal sinus region, extending downward into the ethmoid region and backward into the cranial vault. Operation again confirmed the diagnosis of osteoma of the frontal sinus, but the patient died of a complicating meningitis.

The lesson to be drawn from these cases is not that osteoma of the frontal sinus can be diagnosed by the roentgen ray—that is self-evident—but that roentgenographic study of all doubtful head cases should be made as a routine.[2]

THE SPREADING POWER OF COAL OILS *

TORALD SOLLMANN, M.D.

CLEVELAND

P. N. Leech[1] and I[2] independently observed that the addition of a little asphalt to melted paraffin greatly lowered its surface tension toward water, so that a very much thinner and more even film than with pure paraffin is formed, and very much more rapidly. In reflecting on this phenomenon, it occurred to me that it might be utilized to secure rapid and extensive spreading of the oil in fighting mosquito larvae, thus increasing the efficiency and lowering the cost of the oil treatment.

Experiments showed that kerosene has a low spreading power, and that this is actually enormously increased by the addition of asphalt. If kerosene is dropped on a dish of water, it collects into rather small plaques, and spreads very slowly, if at all. If 0.1 per cent. or more of asphalt varnish ("B-asphaltum, Cleveland Window Glass Company") has been added, it spreads at once over the entire surface of the water.

Similar results were observed with gasoline.

However, unrefined oils generally spread perfectly without the addition of asphalt. They presumably already contain sufficient asphalt-like products.

The following crude oils spread perfectly without the addition of asphalt:

Pennsylvania Lower District Crude.
Light Tiona Crude.
Kansas-Oklahoma Crude.
Residue oil left after distillation of the lighter product.
A sample of "No. 4 Road Oil" did not spread.

SUMMARY

The "spreading power" of oils on water is important in their use against mosquito larvae. It should therefore be ascertained, at least by the rough test herein described.

The spreading power depends largely on the presence of asphalt-like products. Most crude oils contain these in sufficient quantity. Some, however, and especially refined oils, need the addition of asphalt. Kerosene requires about 0.1 per cent of asphalt varnish.

Clinical Notes, Suggestions, and New Instruments

BONE-HOLDING FORCEPS *

Robert Emmett Farr, M.D., Minneapolis

The multiplicity of bone forceps designed to overcome the displacement of bones is sufficient evidence that most of these devices have certain shortcomings. In order to meet the requirements, such a device must have sufficient strength, and adaptability to bones of different diameters. Its application should be simple and it should have means of overcoming displacements by manipulations.

The instrument herein described consists of two long bone-holding forceps which may be readily united to each other by a carriage and worm-drive arrangement which requires the forceps to be brought parallel to each other in one plane only. Once assembled, extension may be made by means of the worm drive, which is operated by means of a two-way reversible ratchet. Movement in one plane may then be accomplished by moving the handles of the forceps over the screw, which acts as a fulcrum. Movement in the lateral plane is achieved by means of a ratchet propelling the carriage on one stationary blade of the forceps. It will therefore be seen that once the device is assembled, displaced fragments of bone may be brought into any desired position by the manipulation of either of the ratchets or of the forceps handles. The bone-grasping end of the forceps is so designed as to allow their application to bones of any size and to leave free approximately one-third of the surface of the bone; these free surfaces lie in the field of operation so that transplants or other mechanical appliances may be used without the necessity of removing the forceps.

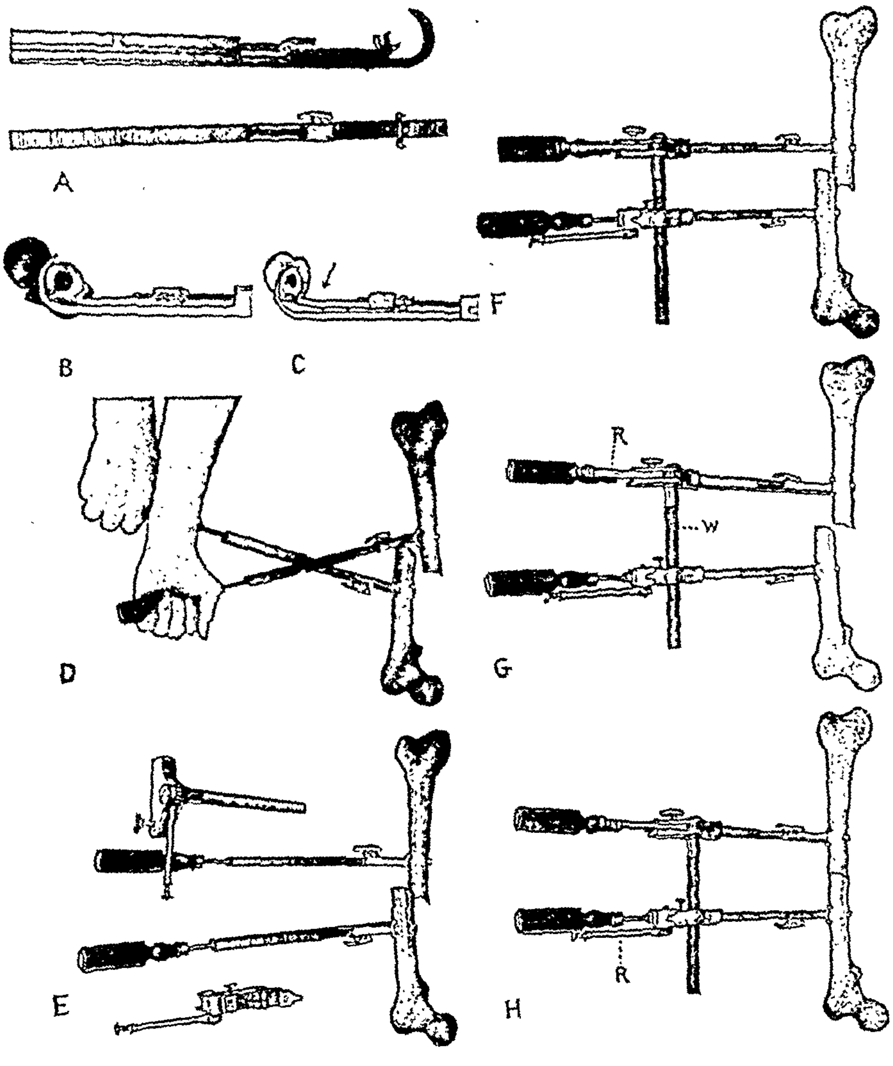

Fig. 1.—*A,* Bone-grasping parts of forceps; *B,* forceps grasping large bone (femur); *C,* forceps grasping small bone (ulna); note change in position of proximal grasping surface, bringing transplant area upward into field; *D,* forceps applied to femur before assembling; *E,* forceps parallel; worm drive, split nut and carriage ready for assembling; *F,* forceps assembled; *G,* extension applied by means of worm drive (*W*) propelled by ratchet (*R*); *H,* lateral displacement overcome by means of ratchet (*R*).

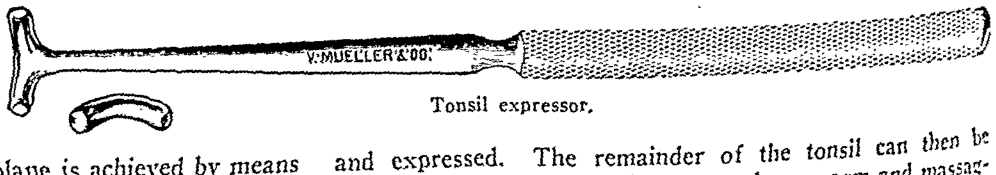
A TONSIL EXPRESSOR

Julius H. Hess, M.D. (Chicago)
Major, M. R. C., U. S. Army
Fort Riley, Kan.

Examination of the teeth and tonsils in a large series of cases of endocarditis, rheumatism and chorea has demonstrated that many of the patients are suffering from alveolar abscesses and infected tonsils. The removal of such teeth is a simple matter even during the course of the disease, but only a few men have had the temerity to advise tonsillectomy at the height of the infection in acute cardiac conditions. Believing that much could be accomplished by evacuating the pus which has accumulated in the tonsils in many of these cases by expression and massage of the tonsils, I have devised an instrument which has been found of practical value in our cardiovascular and rheumatic wards for diagnostic purposes and frequently for treatment.

Set at right angles to a 7½-inch steel handle is a cross-piece of steel three-quarters inch in length and three-sixteenths inch in diameter, well rounded on all its surfaces and highly polished. The crosspiece has an anterior-posterior curvature of three-sixteenths inch and a curvature of one thirty-second inch on its upper surface.

The instrument is used by passing it in at the angle of the mouth opposite to the tonsils to be expressed and by applying it first at the superior angle of the fossa external to the pillars and pressing upward and outward. In this way the superior pole of the tonsils is exposed and expressed. The remainder of the tonsil can then be exposed by anchoring the instrument by one arm and massaging the tonsils from above downward with the other arm, which is made possible by the concave upper surface of the instrument. At all times the instrument should be kept in front of the anterior pillar.



Tonsil expressor.

---

* Read before the Section on *Orthopedic Surgery* at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, *1918.*

The advantages of the instrument are that: (1) it offers a simple means of exposing the entire tonsil for diagnostic purposes; (2) it can be used to advantage in expressing pus from the tonsils for bacteriologic examination; (3) the tonsils can be evacuated without an anesthetic without pain to the patient two or three times a week, and the patients rarely object to the repetition of the treatment. In very sensitive throats a 2 per cent. solution of cocain may be used before treatment.

In many cases one or more large pus pockets are present. The most frequent seat of the pus pockets in our cases has been near the upper pole between the anterior pillar and the tonsil. This part of the tonsil is often completely buried behind the pillar and cannot be exposed by simple retraction of the pillar.

Massage and expression of the tonsil in no sense replaces tonsillectomy. It is recommended only as an emergency measure where the radical operation is contraindicated during the height of an infection.

ACCIDENTAL INJECTION OF BILE DUCTS WITH PETROLATUM AND BISMUTH PASTE

Adolph Reich, M.D., New York

Miss J. de M. had a pelvic operation two years before consulting me. A few days after the operation she was taken with pain over the region of the liver, and a swelling, which appeared in the midaxillary line, was incised and discharged pus, leaving a persistent fistula between the tenth and eleventh ribs. She asked to be relieved of this fistula.

In order to know the direction of this fistula, I injected about 2 ounces of petrolatum paste and bismuth with a melting point of 110 F. Immediately there was considerable pain in the pit of the stomach, the following day the patient's temperature was 102 by mouth, the urine was dark brown, she was jaundiced, and she could not hold anything on her stomach. Figure 1 shows the bile ducts filled with the paste down to the duodenum.

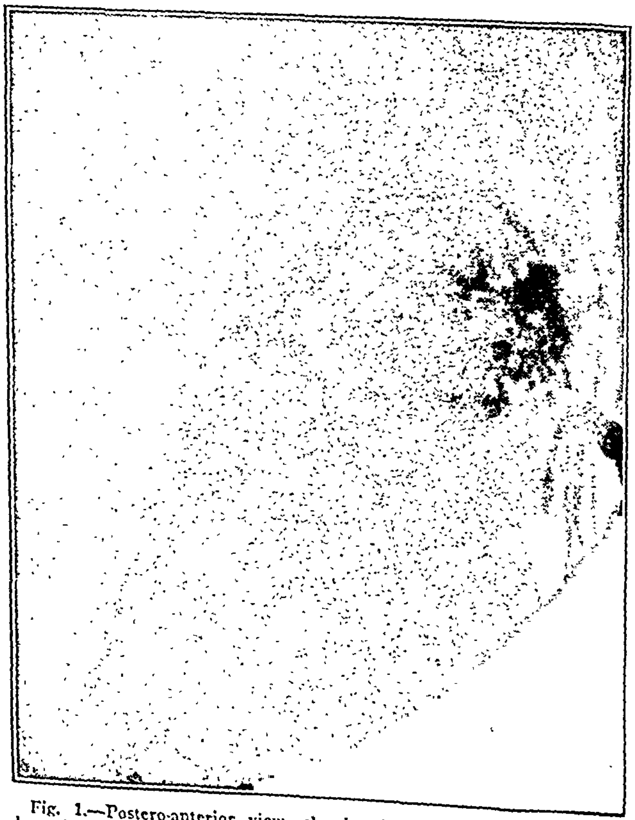


Fig. 1.—Postero-anterior view, showing bile ducts filled with paste down to the duodenum.

The treatment consisted of local hot applications, morphin for the pain, calcined magnesia one-half ounce every two hours until the bowels moved freely, and injection of warm olive oil through the fistula, about 1 ounce or more every three hours. The next morning the bowel movements had a dark slate color and kept so for two weeks, and the temperature fell to normal within one week, and all symptoms of the obstructive jaundice passed off gradually.

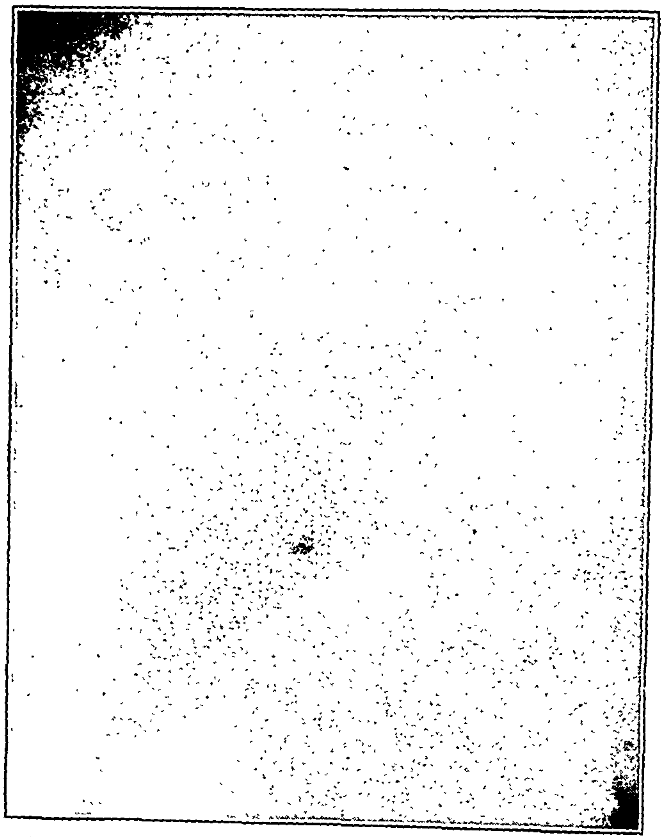

Fig. 2.—Anteroposterior view taken recently; bile ducts free from bismuth; a few grains of bismuth near the opening of the fistula.

Figure 2, taken recently, shows the bile ducts entirely free from bismuth and only a few scattered grains of bismuth near the opening of the fistula. Pus is discharged only occasionally, and some of the bismuth finds its way out.

STUDIES OF ROENTGENOGRAMS OF THE ACCESSORY NASAL SINUSES

WITH A DESCRIPTION OF A NEW METHOD OF TAKING SUCH PICTURES: PRELIMINARY NOTE

Max Unger, M.D., New York

In common with other nose and throat specialists, I have felt the disappointment resulting from the lack of help in diagnosis furnished by roentgenograms of the accessory nasal sinuses, especially in cases of suspected ethmoid and sphenoid disease.

The method now employed in the taking of roentgenograms of the accessory nasal sinuses is to put the plate in front of the patient's face and to shoot the roentgen ray through from the back of the head. This gives us an excellent picture of the frontal and maxillary sinuses, but the recognition of the ethmoids and sphenoids is a matter of guesswork. This is due to the fact that the latter cells are small, deeply situated and overlapped by the frontal and maxillary sinuses, the turbinates and the nasal bones.

Accordingly, I have devised a new method of taking roentgenograms of the sinuses. I employ a roentgen-ray film that is cut to the shape and size shown in Figure 1. This film is wrapped in waterproof paper, similarly to dental films. A piece of card-board is included next the emulsion side of the film for purposes of protection and ease in handling.

When a picture is to be taken the film is inserted into the subject's mouth, the narrow end touching the posterior pharyngeal wall and the broad end projecting from the mouth. The roentgen-ray tube is adjusted above the head so that the rays pass directly downward and at right angles to the film. Sometimes a slightly obtuse angle forward is necessary, especially when the film cannot be pushed back completely. Sometimes, also, cocainization of the throat is necessary to overcome gagging.

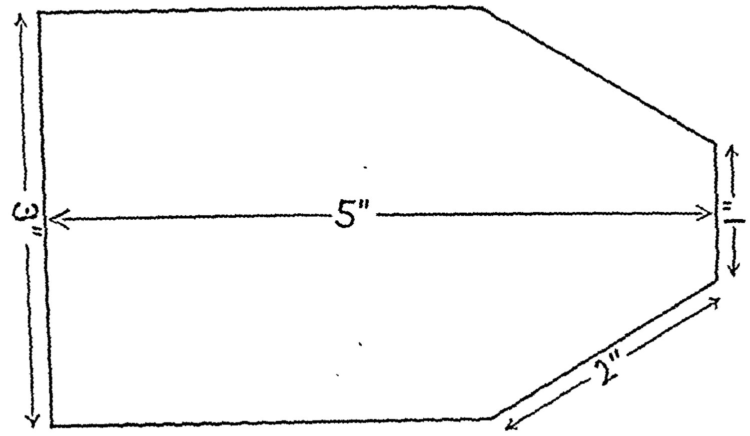

Fig. 1.—Shape of film.

This method has the advantage that the pictures show all four accessory nasal sinuses in isolated positions, without any overlapping. The ethmoids and sphenoids are shown best, but the frontal and maxillary sinuses are also shown in their horizontal dimensions, knowledge of great value when operations on these sinuses are contemplated. The maxillary sinuses are also shown in their relations to the teeth.

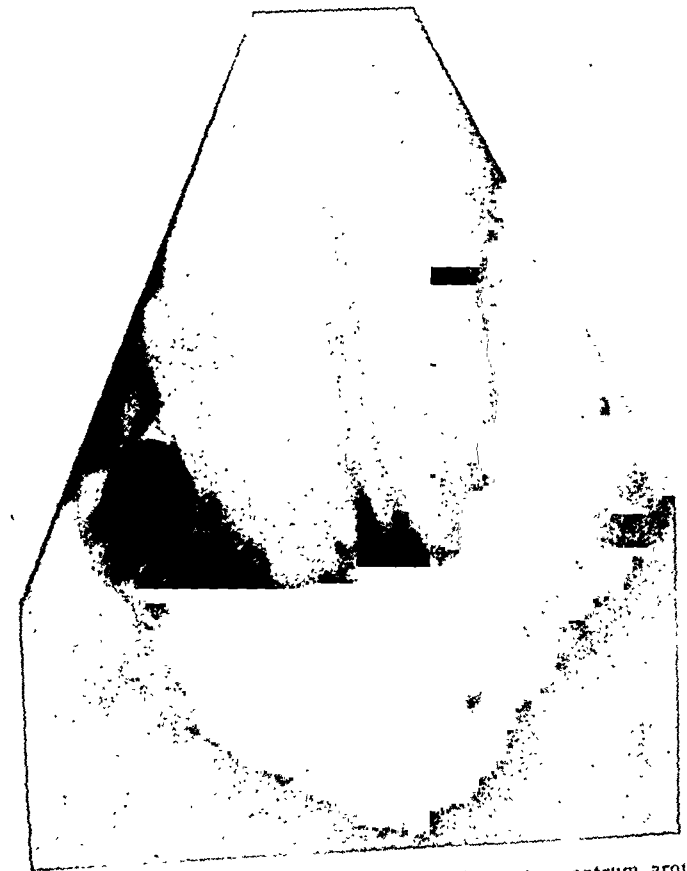

Fig. 2.—Sphenoid at apex; ethmoidal cells in center; antrum around last two teeth on left.

The method should prove of value in the investigation of fractures and the location of foreign bodies, such as bullets, at the anterior part of the base of the skull.

This is a preliminary report and deals only with the use of this method on the cadaver. A later communication will deal with its use on the living.

AN AUTOMATIC DISTRIBUTOR FOR NEUTRAL SOLUTION OF CHLORINATED SODA (DAKIN'S SOLUTION)

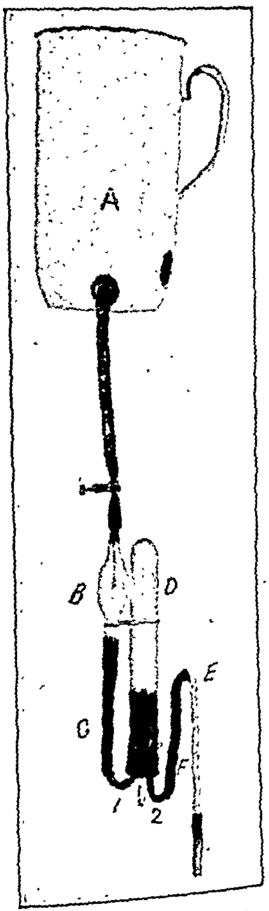
LYMAN J. STRONG, M.D., BUFFALO

The successful use of Dakin's solution (neutral solution of chlorinated soda) depends on its delivery in sufficient quantity to all parts of the infected wound at regular and frequent intervals. These conditions can be obtained by a simple apparatus.

Wounds vary in size; therefore, this apparatus has two controls, one for time and one for quantity.

An irrigator can, *A*, is elevated on the head of the bed. A short piece of rubber tubing connects with a drop tube, *B*. A screw clamp on this piece of tubing controls the rate of flow through the dripping apparatus. For example, to deliver 80 c.c. every two hours, the screw clamp is set so that 10 drops each minute fall from the drop tube.

A large size test tube, *D*, of about 100 c.c. capacity, is fitted with a three hole rubber stopper. This test tube serves as a reservoir to collect the solution from the drop tube. Through one hole of the stopper a piece of glass tubing, placed so that it extends the entire length of the test tube, controls the pressure in the test tube when emptying and filling. Through the other two holes of the stopper are pieces of glass tubing bent in short-armed U's. U Tube 1 and U Tube 2 convey, respectively, Dakin's solution into and out of the test tube.



Automatic distributor for neutral solution of chlorinated soda.

U Tube 1 is connected with the outflow from the drop tube by a rubber tube, *C*. U Tube 2 is connected with U Tube E, which has one long arm and one short arm. This is done by a piece of rubber tubing, *F*, to the short arm. This rubber tubing should be long enough for U Tube E to be elevated or lowered a distance equal to the length of the test tube. Raising U Tube E increases the quantity of fluid discharged into the wound. For example, to deliver 80 c.c. every two hours, the drip is set at 10 drops per minute. U Tube E is set three-quarters up the test tube.

The long arm of U Tube E connects with regularly used Dakin's tubes that are planted in the infected wound.

As fluid runs from the can through the drop tube; it is conveyed by Tube C into the test tube, which stops it from flowing into the wound until it reaches the level of U Tube E. When it reaches this level a siphon is formed, and the quantity of fluid in the test tube is expelled at one time into the wound.

This apparatus is practical and has discharged fluid at intervals of one minute and intervals of two hours with the regularity of a good clock. The quantity may be varied from 5 to 100 c.c. It can be made in any hospital or laboratory. It depends entirely on gravity, so that it always works.

482 Williams Street.

Conditions Demanding Blood Transfusion.—Positive indications in chronic anemia will be found in the case records (prolonged suppuration, infection and fever, and in sluggish wound healing), in the information derived from repeated blood counts, hemoglobin estimations, and blood pressure determinations.—*Review of War Medicine and Surgery.*

Military Medicine and Surgery

RAPID METHOD FOR DETECTION OF OVA OF INTESTINAL PARASITES IN HUMAN STOOLS

CHARLES A. KOFOID, Ph.D., Sc.D.
Major, Sanitary Corps, U. S. Army
FORT SAM HOUSTON, TEXAS
AND
MARSHALL A. BARBER, Ph.D.
Major, Sanitary Corps, U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

The military significance of infection by hookworm disease among recruits and troops of the United States Army might be inferred from its known clinical symptoms. That it is characterized by anemia, edema, intestinal disturbances and by a disinclination to physical effort is well known. Testimony and statistics add to these charges the facts that morbidity and mortality tend to be higher among troops from the area of hookworm infection than among those from outside that area. Comparisons of the records of examinations of new recruits from the hookworm area[1] reveal the fact that white men with this infection make lower records than do the noninfected, literate and illiterate. There is also some evidence that hookworm infections tend to impede the progress of recruits in discipline and instruction. The guard house, venereal isolation camp and the hospital show higher rates of infection than does the camp as a whole. Hookworm disease appears to be one of the causes tending to increase the ratio of noninfectives among our troops and to lower the standard of their efficiency.

Because of the numbers to be examined, the nature of the available equipment and the desirability of not encroaching on the duties of a medical staff already occupied with more important work, it was essential that any method used in detecting this infection should be rapid, accurate, simple, adapted to the utilization of a changing personnel in large part, and that it should not require elaborate apparatus or extensive laboratory equipment.

COMPARISON OF VARIOUS METHODS

The direct microscopic examination of a small sample of the fecal specimen is inaccurate because of the minuteness of the sample used, and impracticable because of the length of time required to make a fair examination. The greater efficacy of the brine flotation-loop method in the detection of worm ova as compared with the ordinary smear method is shown in the accompanying table, in which nine-day periods are compared. The salt flotation method is obviously inferior in the detection of *Strongyloides*.

Only hospital cases, based on records at Camp Jackson, are included in the table. The great variability in the daily hookworm precentages is probably due to the varying proportions of patients from the Northern states.

The centrifuge method is at once precluded by the difficulty, if not impossibility, of securing an adequate number of instruments to accomplish a work of such magnitude, and the added difficulty of securing the requisite tubes and other glassware essential to equip and maintain facilities adequate to care for the number of examinations to be made. It also calls for extraordinary care in cleaning the glassware used, for hookworm eggs are quite adhesive to the surface of glass. This is a difficulty of considerable importance when laboratory helpers are inexperienced, and adds much to the burden of supervision.

The centrifuge is also inaccurate, probably because of the small size of the samples used. The standard fecal sample collected for this method in the Army is contained in a 2-dram vial. Negatives for hookworm by this method as used by the senior author in the Department Laboratory of the Southern Department were examined by the salt flotation method by us and found in about fifty examinations to show a 40 per cent. increase in infections. That is, the percentage was increased from 10 to 14. This was borne out by the fact that, whereas the percentage of infection by the centrifuge method was about 8 per cent. in 7,000 examinations, it rose to from 14 to 20 per cent. among troops from the same general localities when the salt flotation method was applied.

COMPARATIVE RESULTS IN DETECTION OF OVA

1918 June	Ordinary Smear Method Number Examined.	Positive Hookworm.	Percentage Positive.	Remarks.
10	205	13	6.3	During nine-day period the same total of examinations as that of the hookworm gave the percentages: Ascaris ....1.1 Hymenolepis nana .....0.6 Trichuris ....0.3 Strongyloides ....0.6 Oxyuris 0.0
11	132	23	17.7	
12	153	24	15.7	
13	135	19	14.1	
14	150	11	7.3	
15	116	9	7.7	
17	144	3	2.1	
18	106	14	13.2	
19	99	11	11.1	
	1,240	127	10.2	
	Brine Flotation-Loop Method			
20	109	40	37.5	During nine-day period the same total of examinations as that of hookworm gave the percentages: Ascaris ....1.1 Hymenolepis ....0.8 Trichuris ....0.8 Oxyuris ....0.08 Strongyloides 0.0
21	96	34	35.4	
22	146	50	32.1	
24	146	48	34.1	
25	152	39	26.2	
26	128	26	20.3	
27	120	26	21.7	
28	120	22	18.3	
29	116	25	21.6	
	1,133	310	27.1	

The elaborate sieve-sedimentation method of Hall[2] is not adequate to the military necessities because of the fact that it can be operated only in a well-equipped laboratory and requires an expensive, elaborate and somewhat permanent installation. It seems not to be rapid, and would require great care in cleaning to prevent a carrying on of infection, when the sieves are used in rapidly succeeding examinations. Its accuracy in cases of light infections should also be tested.

The culture method of Looss[3] and of Fülleborn[4] has been used by the senior author in the laboratory of the California State Board of Health. This is an exceedingly accurate method, revealing the lightest of infections. But it requires regulated incubators to run to a schedule of operations, constant supervision and inspection, a delay of about five days before results can be reported, and considerable washing of glassware, including, when paper Petri dishes are used for culture, the centrifuge tube (possibly omitted), Syracuse dish and a pipet. The active larvae make the detection of infections quickly decisive in the case of positives. Skill in differentiating *Strongyloides* larvae from those of hookworm is essential. The use of culture mediums and water free from free-living earth and water nematodes is also a desirable precaution. This method is thus not readily adapted to military conditions by reason of the installation required, the amount of cleaning and the precautions necessary. The delay incident to the hatching period so extends the time between collection of the sample and report of the results as greatly to increase the material on hand under supervision, and the bulk of the clerical work awaiting completion. No opportunity has been afforded to compare it in detail with the brine flotation-loop method as to their relative accuracy in detecting light infections. The culture method detects hookworm and *Strongyloides*, both with free-living stage, but does not give any clue to the presence of the cestodes, and of *Ascaris, Trichuris* and *Oxyuris*.

THE BRINE FLOTATION-LOOP METHOD

In view of the difficulties attending the use of the methods enumerated above, under Army conditions, the method here described was devised after considerable experimentation. The senior author in his work on hookworm in the gold mines of California for the California State Board of Health had adopted the culture method after prolonged experimentation with the centrifuge method and unsuccessful attempts to find a satisfactory sedimentation, flotation or filtration method that would effectively utilize a large sample and detect light infections. The junior author had had long experience in Malaysia, China and the Fiji Islands with the International Health Board in the critical use of various methods of examination, especially that of the centrifuge, under field conditions.

The method finally perfected by us may be designated as the brine flotation-loop method. It consists in mixing a large fecal sample thoroughly in concentrated brine, in a paraffined paper can of from 2 to 3 ounces capacity, forcing the coarse float below the surface by means of a disk of No. 0 steel wool, and then allowing the can to stand one hour for the ova to ascend. The surface film is then looped off with wire loops, one-half inch in diameter, and examined on a slide without a cover glass.

The method has been tested in the Southern Department under the senior author's direction in more than 100,000 examinations of varying ratios and degrees of infection by about seventy-five different examiners, under diverse field conditions, and has been found to be efficient and practicable.

TECHNIC

The stools for examination are collected at reveille in the morning at the company latrines by a collecting squad consisting of sixteen enlisted men in charge of a sergeant and under command of a medical officer. The men from a given company are in charge of a line officer. They are marched to the latrine in alphabetical order and the roll is called from the roster by the sergeant in charge of the men. On admission to the latrine each man is identified and given a container, bearing the designation of the organization and his roster number, a sheet of waterproof paper, and half a tongue depressor as a collecting stick. He is instructed to defecate on the paper and to fill the can one third full of feces. Men unable to furnish a specimen are given salts, under the supervision of the medical officer, and are moderately exercised. The men submit their sample to the collector for inspection on leaving the latrine to prevent the passing in of empty cans. Substitution is forbidden. In practice, this squad can collect the specimens from an entire regiment, make the first delivery at the laboratory at 7:30 a. m., and complete the collections at 10 a. m. On an average from 3 to 10 per cent. of the organization on a complete roster fail to furnish specimens by reason of absence, detached service or failure to defecate.

The receptacles used as containers for fecal specimens for examination for ova of intestinal parasites serve not only to receive the fecal specimens at the latrines but also as the mixing dishes from which the ova are subsequently looped for examination, and themselves bear the results of their examination to the recorder's table. The use of glass or tin containers is precluded by the cost, labor of cleaning and danger of carrying over of infection by adhesion of ova to the sides of the dish. We have therefore used paper and pasteboard containers, which may be wasted after use. We have in emergency used paraffined paper drinking cups and standard hospital sputum cups, but have found the most satisfactory container to be the standard 2-ounce paraffined paper drug cans with tin bottom and paper top. Similar cans with paper bottom and top are more liable to be unsealed by the solvent action of the contents. Open drinking cups permit evaporation and increase the odor and liability of carrying over of ova by flies. Heavy paraffined "Kleen Kup" tumbler-shaped containers are satisfactory for shipping specimens some distance.

These cans are about 1½ inches in diameter and 2½ inches high and are made up from specially constructed paper tubing made from stock paraffined on the inner face. Their capacity is normally 2 ounces and varies from 50 to 80 c.c. according to the brand or factory. Certain brands either have no coating or are so lightly coated that it was necessary to treat them to a dipping or to an inside coating of hot paraffin or sodium silicate to render them brine-proof. Paraffin-coated brine-proof cans that will resist soaking up by brine and feces for a number of hours can be obtained from commercial sources at present and are fairly satisfactory for this method of stool examination. The practical advantage of containers of these dimensions is that they will rack snugly in the compartments of the pasteboard fillers which hold three dozen each, of standard shipping cases for eggs, which hold thirty dozen each. To facilitate the handling of a single filler we have used specially constructed pasteboard trays with tape loops for handles into which a single filler fits. These trays are very convenient for use in the preliminary marking of the cans, the arrangement of the numbered cans and for subsequent handling at the latrines and in the laboratory.

In the examination of troops in the Army, each can is marked with the designation of the organization and the roster number of the man whose specimen it is to receive. Thus, 305 Cav. H-16 is for the sixteenth name on the roster of Troop H of the Three Hundred and Fifth Cavalry. Cans were at first marked on both top and side: the former for convenience in picking out a particular can at the latrine, the latter for use in the laboratory. These cans were marked with wax pencils or on strips of adhesive tape in ink on the tin tops, and the sides similarly marked or with lead or colored pencil or in ink. Pasted typewritten labels are unsatisfactory, as they may soak off if wet or peel away if dry. The most satisfactory labeling thus far found is that written in "Eternal" ink. This is not removed by water or brine, and sinks into the paper so deeply that it cannot be rubbed off. It is also clearly visible on the wet can. The cans for a given organization, such as a company of a regiment, are serially numbered, and on receipt at the laboratory from the latrine are usually not in numerical order. In order to detect shortages, eliminate confusion of indistinctly written numbers, and facilitate entering results on the numerically and alphabetically serial roster, the cans are first arranged in numerical order on a number board and then racked in order in the sockets of serially numbered wooden racks holding ten cans each. They are then passed to the mixing table where they are prepared for the examiners.

The stool is prepared for examination by stirring the specimen thoroughly in concentrated brine with a small wooden stick until the brine is considerably discolored and the contained ova released from the feces. The amount of stool to be stirred varies with its consistency and composition. Not more than one third of a canful is ordinarily used; if the sample submitted is too generous, the amount is reduced. The can is filled nearly full with brine, and the stool, if putty-like and resistant, is broken up against the sides of the can.

In some instances of putty-like stools the release of the ova is facilitated by scouring the stool up with steel wool on the end of the stick, against the side of the can. After stirring until the desired consistency is attained, the stick is withdrawn and a circular filter of No. 0 or No. 1 long fiber steel wool is carefully pushed down through the fluid to the bottom of the can with the stick. This effectively removes from the surface the lighter coarser float, breaks up the air bubbles, and leaves the surface clear of coarse particles and suitable for looping of the floating ova. Stirring the stool with the electric soda mixer gives quickly a suspension of the stool, but forms too many air bubbles for satisfactory looping.

If too much wool is used it will interfere with the ascent of the ova. If too little is used it will not remove the float. As a rule a lightly compressed disk, one-eighth to one-fourth inch in thickness, is sufficient. From 1 to 2 pounds are sufficient for 1,000 specimens. Other materials, such as disks of wire netting, excelsior and southern moss will serve the same purpose, but less successfully by far. The southern moss may introduce fresh water nematodes and their eggs and larvae.

Since there is danger of contamination of adjacent cans through stirring and in putting in the wool by splashing over from one can to another, it is a wise precaution to remove the can from the rack during the preparation. As an additional precaution to prevent the accidental transfer of a stick from one can to another during the mixing of a rack of cans, it is customary to place sticks in all of the cans and leave them there when not in use until the entire rack is finished.

The specimen is prepared for microscopic examination by looping off the surface film to an ordinary glass slide. The loops for this operation are prepared from unraveled window screen or similar fine galvanized wire. They can be made up rapidly from 6-inch squares of wire netting by twisting the individual wires into the loops. Each loop is formed around a glass tube or wooden cylinder about one-half inch in diameter, the shorter end twisted around the longer, which forms the shaft to close the loop, which is then bent out at right angles to the shaft. The surface film will usually adhere to the wire when the submerged loop is lifted from the brine. Ova in the film are removed with it. It has been found advisable to loop the surface near the sides as well as the center of the can. For this purpose the loop may be molded to the arc of the can on one side.

The number of loopfuls necessary to make a fair sample for microscopic examination depends on the capacity of the film removed. About ten loopfuls will skim the entire surface of the can and form a pool of brine conveniently handled on an ordinary microscope slide with a mechanical stage. One skimming does not by any means remove all the ova, as they are not all in the immediate surface. If ova are present in any numbers they may be obtained at once, if the stirring has been thoroughly done. It is customary for the cans to stand for one hour to allow the ova to accumulate in the upper layers. Ova may still be found at the surface after twenty-four hours, but their numbers are decreased. In warm weather they may have entirely descended in five hours.

The following test shows the relative hourly abundance of hookworm ova in the surface film on a can mixed with brine at 8:45 a. m., until they disappeared:

The brine and ova were poured off into another can at 9:15, being distributed, by the pouring, throughout the fluid. Four loopfuls were placed on the slide and ten fields were examined. At 9:15 a. m. there were 69 ova recorded; at 10:20, 169; at 11:20, 150; at 1 p. m., 85; at 2:10, 20; at 3:15, only 3, and at 4 p. m. none. The temperature during the period was from 90 to 95. The maximum number of ova appeared at the surface about an hour after they were uniformly stirred, and seven hours after mixing, all had descended from the surface.

From tests made under other conditions it is evident that there is considerable variation in the rate of ascent and descent of the ova in the brine in different stools and at different temperatures.

For a time we marked off an ellipse 1½ inches by ¾ on the slide with a wax pencil to assist in confining the pool of brine on the slide, but this was later abandoned as unnecessary.

In the cases of viscid, opaque and fatty stools, considerable dilution may be required. This may be done with a few drops of a mixture of equal parts of glycerin and brine stirred into the pool on the slide. The glycerin clears the more opaque particles and renders the ova more easily visible.

The following modification of the salt flotation-loop method has been used by the junior author at Camp Jackson, S. C., for routine hospital examinations and for a limited number of stools sent from the camp:

Specimens are sent into the laboratory in tin containers provided with lids. Salt flotation and loops are used exactly as in the method describe below, but instead of filtration by steel wool the coarser floating particles are skimmed off by means of a spoon before the ova have time to rise. The spoon is scrubbed with a brush and carefully washed under the hot water tap after each use. When cans are used a second time they are very carefully cleaned and dried.

It is obvious that the sole advantage of this modification is in the saving of materials. Further, it is adapted only to work on a comparatively small scale and in a laboratory supplied with skilled workers and with a hot water tap for the proper cleaning of utensils. It is not to be recommended for field work on a large scale or for any work in which pasteboard containers and steel wool are obtainable.

COMMENT

Contamination of adjacent cans by droplets of the surface film splashing over from an infected can to a negative one may readily occur when the loop catches on a stray fiber of the steel wool and is suddenly released, or when the film in the loop breaks on contact with the slide. For this reason the can and slide should be moved away from the rack while the pool is being looped off. The viscosity of the surface film may vary greatly with the nature of the stool. It is markedly decreased by slight additions of such disinfectants as tricresol and phenol (carbolic acid) or by alcohol, which is useful in removing air bubbles from the surface. Formaldehyd solution tends to curdle the mixture, and delays the ascent of the ova and reduces the numbers in the surface film.

These variables, which affect the opacity and contents of the loop and the number of ova it removes, render any uniformity of looping and resulting thoroughness of examination practically impossible. In practice from three to seven loopfuls are generally used; but the number in the course of numerous examinations will vary from one to twenty. It is obvious that these variables will introduce a margin of error in the detection of ova only among the lighter infections.

The ova of parasites such as *Ancylostoma duodenale*, *Necator americanus*, *Ascaris lumbricoides*, *Oxyuris vermicularis*, *Trichuris trichiuria*, *Taenia saginata*, *Taenia solium*, *Hymenolepis nana*, *Hymenolepis diminuta*, and *Dipylidium caninum* and of trematodes are floated up by the brine into the surface layer of the pool without distortion or noticeable change in appearance during the usual period of examination. Cysts of *Endameba coli* and *histolytica* and of *Giardia intestinalis* are also floated up. Since the ova are at the surface, it is not advisable or necessary to use a cover glass.

The surface of the pool of brine is thoroughly searched with the aid of the mechanical stage. To reduce the amount of focusing, the convexity of the surface of the pool may be reduced by spreading it over the slide and extending the amplitude of the movements of the mechanical stage.

The microscopic equipment most useful is the typical high grade instrument with 16 and 4 mm. objectives and × 5 or 6.4 and × 10 oculars or their equivalents. The searching is done with the low power objective and low power ocular since the latter is less tiring in long-continued examinations. For closer scrutiny the 4 mm. objective may be used with care on objects in the surface film without cover glass.

To render the ova more distinctly visible it is essential that the microscope be provided with a substage condenser and that the illumination be reduced by closing the iris diaphragm or lowering the condenser so as to increase the sharpness of definition of all objects in the field and to bring the egg membranes into relief. This assists in the quick differentiation of ova from objects of similar shape and opacity. The amount of searching necessary to make a fair examination is a function of so many variables that no arbitrary rule can be laid down. The degree of dilution, stirring, flotation, the amount of the surface fluid in the pool, its extent and convexity, the consistency and opacity of the fluid and its solid contents, the nature and number of the particles floated to the surface, the number and size of air bubbles, fat cells, oil globules and starch cells, all combine to complicate the search for ova. It is advisable to search a considerable area rapidly, and especially in the case of opaque fluid and confusing particles, to search a part of the area minutely or make an additional dilution. Experienced examiners on an average give from two to three minutes to the examination of a specimen containing on an average four to five loopfuls spread over an area of approximately a square inch on the slide.

Infected stools, or positives, are usually detected in the first field or first run across the slide examined. In a test case of 550 positives of hookworm, most of them very light infections in Oklahoma and Texas recruits, detected on five consecutive days by five experienced examiners and recorded as found or not in the first run across the slide, there were 180, or 30.5 per cent., reported as seen in the first run. Infections obviously reduce the time required for examination in most cases. In a relatively few cases, estimated at not more than 5 per cent. in our experience with the examination of more than 100,000 men in the Southern Department (Texas, Oklahoma, New Mexico and Arizona), several ova only have been found in the whole slide examined. In rare instances only a single ovum is found. These very light infections and the negatives require more time for a complete examination than do other positives.

It is obvious that the rate of examination and daily score of the examiner will be in part a function of the ratio of positives to the whole and of the average degree of infection. With numerous positives and heavy infections, which are usually coincident, the rate of the expert examiner may easily be doubled over that when positives are few and infections are light. The experience, skill, industry and thoroughness of the examiner are also factors determining his daily score, as well as the nature of the stools as conditioned by diet and modified by the skill or lack of it on the part of the mixers.

A skilled examiner will complete from 150 to 250 examinations daily under average conditions. With the assistance of a looper the rate can be speeded up to one per minute; but the resulting eye strain renders this inadvisable as a daily routine. A staff of fifteen examiners can maintain a rate of from 2,000 to 2,500 examinations daily and attain 3,000 under favorable conditions of cooperation and effective supervision of the mixers. A staff of twenty examiners can complete a full regiment daily. Supplemental aid of approximately one man in the field collecting squad and one man in the laboratory and clerical squad for each examiner is necessary to collect, prepare, record and dispose of the specimens and attend to the policing of the laboratory.

The time required for the physician inexperienced in laboratory work to become efficient in this method is brief. Enlisted men with some experience in college, university or Army laboratories acquire a reliable degree of accuracy with several days' training and supervision, as shown by test, and may in some instances also acquire the speed of an experienced examiner in this time.

In our experience after experimenting with various methods of making records of the results of the examinations we have finally adopted the roster system with special recorders whose only duty is to make the record on the primary roster. Efforts to make a card system were futile, for even with experienced examiners, entries are sometimes omitted or incorrectly made. The difficulty arises from the constant intermittence of the two distinct types of work, microscopic and clerical.

For his own information and for the quick ascertainment of the day's totals and percentages, each examiner keeps a daily score on which is entered the serial number of each rack of specimens examined, the number of cans examined, negatives, hookworm, tapeworm, etc. The totals are quickly cast up, transferred to another sheet and the grand total arrived at.

The results of the examination of the individual cans are indicated by certain conventional signs. A negative can carries only the loop. Positive hookworm is indicated by the inserted slide, dwarf tapeworm (*Hymenolepis nana*) by a mixing stick, and any other infection by the written name on a slip of cardboard. When thus designated the rack is passed to the recorder's table who enters the results on the rosters, using red for hookworm, blue for all other infections, and lead pencil for negatives. Since the cans are arranged in numerical order within the racks, the entries on the roster fall consecutively in variously ordered groups of ten, and the recording proceeds rapidly. The arrangements of the cans in serial order and the entry of the results in sequence tend to eliminate errors arising from misplaced entries and indistinct numbers.

A rubber stamp is used to allocate on the roster a tabulated summary of the results within an organization such as a company or regiment. It provides for entries of infections by hookworm, *Hymenolepis nana*, a blank for writing in the rarer infections, negatives, no specimen, absent, number examined, and total on the roster. Additional spaces provide for revisions as follow-up specimens come in later.

This system reduces the clerical work to a minimum and makes possible the reporting in at the close of the day of the lists of the infected men for treatment. When the work of an organization is closed, the duplicate roster with all the infections and unexamined men indicated thereon is returned to the regimental surgeon and the triplicate similarly marked, to the division, district or camp sanitary inspector, and the primary roster remains as the permanent record for filing with the officer in charge of the hookworm survey.

The accuracy of this method depends on a number of variables, the size and consistence of the specimen, the thoroughness of stirring, the proper amount of steel wool, the care in looping, the opacity of the fluid, and the extent and thoroughness of search made of the material on the slide. Much depends on keeping the focus directly on the surface of the fluid during examination and in training the eye to detect quickly every object resembling an ovum.

The cases of infection which escape detection are the very light ones in which only a few ova can be found on a slide. Some slides prepared from such infections may have no ova, or the ova may be hidden or overlooked.

Reexamination of slides and cans that are reported by an experienced examiner as negative will sometives reveal a positive lightly infected. Men reported as negative on a first examination may appear as positive on a second specimen and vice versa. This raises the question as to the uniformity of distribution of the ova in the stool and as to the possibility of internal states of host and of parasite influencing the rate of deposition of ova in successive stools.

With a view of testing out the possibility of light infections having been overlooked, a test was made on 100 negatives from colored troops at Camp Travis. Infections in the battalions from whom these negatives were drawn were only sixty-eight in 1,495, or 4.8 per cent. The infections were also light, as a rule. The top fluid of fifty cans was drawn off into a tall cylindric liter graduate and the surface film of this column examined. The cans had stood after stirring for less than three hours, and no brine from thick or viscous stools was used, so as to avoid entangling any ova that might be present. This was repeated on a second fifty and the top fluid of the two lots combined in a slender 50 c.c. graduate. An examination of the surface film of each of these concentrations gave negative results. A subsequent examination within two hours of flotation of 150 negatives by the same method from white troops, showing 219 positives or 8.7 per cent. in 2,505 examinations, revealed one case of ova in one lot of fifty. The other two lots remained negative. In another test of three lots of fifty each from white and colored troops showing 110 infections, or 5.7 per cent., in 1,914 examinations, all remained negative. Thus, in a total of 400 negatives, or eight lots of fifty, of light and therefore presumably easily overlooked infections, only one lot showed evidence of an undetected infection on this test.

It appears from these tests that the number of positives escaping detection by the brine flotation-loop method is small. These tests were made in the negatives from sixteen examiners, eight of whom had had only from three to nine days' experience with hookworm examinations.

No opportunity has occurred for a comparison of this flotation method with the culture method to compare their relative accuracy on identical stools.

ADVANTAGES OF THE METHOD

The great advantage of the brine flotation-loop method lies primarily in the easy utilization of large samples. With large enough containers, receptacles for mixing the entire stool may be utilized, thus eliminating entirely the element of random sampling, except as this may appear in irregular ovoposition or unequal discharge in successive stools. This insures a sufficient number of ova to make detection possible in light infections which other methods, using smaller samples, may fail to detect in a larger proportion of examinations. The method is for this reason a more accurate one.

The method is also a simple one, requiring only the simplest laboratory equipment, aside from the microscope, using available commercial materials and utilizing unskilled labor in large part for its aids. This facilitates the mobility of field operations far from base laboratories, since a permanent staff only for supervision and training is necessary.

It is also more rapid, being in our experience about 50 per cent. more rapid than the centrifuge method. It is also more rapid than the culture method, in the experience of the senior author, since the time required in the mixing, inspection, watering, concentrating, examining the cultures and in cleaning the pipets and Syracuse dishes is easily double that consumed in the flotation method. This is increased if glass Petri dishes are used for culture instead of paraffined paper ones, which may be wasted.

The flotation method also almost wholly eliminates the labor of cleaning apparatus and containers. The only pieces of apparatus to be cleaned are the wire loops from negative cans which may be salved by washing en masse and drying thoroughly, the glass slides, which are rinsed and wiped, and the racks, which are occasionally washed with brush and hose. The container, which serves also as mixing can, the stick and the steel wool are wasted. There is no cover glass or centrifuge tube to be cleaned.

COST

With the exception of the microscope, the use of which is common to all methods, all apparatus and materials used are inexpensive commercial articles. Aside from the microscopes, tables and stools and office fittings, the equipment necessary for handling 2,500 daily costs about $120. The materials necessary for 1,000 examinations in addition to the containers are 1,000 sheets of buckskin paper, 10 by 15 inches, 500 tongue depressors, 35 pounds of salt, from 1 to 2 pounds of No. 0 steel wool, and a certain amount of wastage on loops and slides. The cost in the Army for the salaries and commutation of the officers and pay and subsistence of the men required to make 2,500 examinations daily in a given instance is 6.2 cents per examination, a total of 7.7 cents. There is also expense for office supplies, some clerical work in the preparation of rosters, and of fuel for incineration, which will increase this amount to about 8 cents per examination. Costs of transportation and other overhead charges not included above will also slightly increase this amount according to the varying circumstances attending the survey. If allowance is made for slack time and reductions in rate of supply of specimens incident to Army conditions, the cost will be materially increased. The estimates given are based on optimal conditions and full capacity.

Another advantage accruing from the simplicity of the method and the nature of the materials used lies in the fact that nontechnical labor may be utilized to a large degree, and competent persons accustomed to the use of the microscope may very quickly become efficient examiners. This renders its use on a large scale in military or industrial establishments or in preventive social sanitation both practicable and possible with a relatively small staff of specially trained persons for supervision and administration.

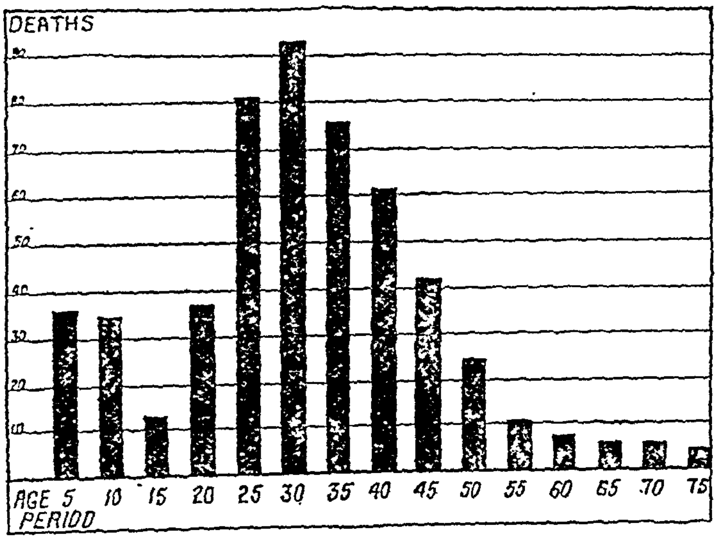
Laboratory Car Metchnikoff, Fort Sam Houston, Texas—Base Hospital Laboratory, Camp Jackson, S. C.

PANDEMIC INFLUENZA AND PNEUMONIA IN A LARGE CIVIL HOSPITAL*

JOHN W. NUZUM, M.D.; ISADORE PILOT, M.D.;
F. H. STANGL, M.D., AND B. E. BONAR, M.D.
CHICAGO

Following the reports of a rapidly spreading and highly fatal pandemic of influenza and pneumonia in the Eastern States, and while the epidemic of influenza was raging at the Great Lakes Naval Training Station, a severe outbreak of this disease appeared among the civil population of Chicago. During the past five weeks, from September 23 to October 29, more than 2,000 patients were admitted to the wards of Cook County Hospital. Of these, 642 died, a mortality of 31 per cent. In the accompanying chart, of the first 500 deaths, it will be noted that the age period of highest mortality falls between 25 and 30 years.

Among the total number of admissions during this period there were 122 soldiers, and thus far twenty-one cases have terminated fatally—a mortality of 16 per cent. So far as the admissions to a large charity institution, such as the Cook County Hospital, may be regarded as an index to the prevalence of the recent epidemic in Chicago, it appears that the disease is now definitely on the decline. Accordingly, it seems pertinent to report the results of an intensive study conducted during the past five weeks in the morgue and the laboratory of the Cook County Hospital.



Age period of highest mortality in the first 500 deaths. The ordinates represent the ages in five year periods, the abscissas the total number of deaths per period. It will be noted that the period of highest mortality is between 25 and 30 years.

CLINICAL PICTURE

The incubation period varied from a few hours to one or two days. Shortly after the arrival of the first fifty soldiers, five of the nurses in attendance on these patients became violently ill, and during the following two weeks more than fifty nurses and twelve of the resident physicians contracted the disease. Three of the nurses died. Blood cultures, nasopharyngeal and tonsil swabs and cultures of the washed bronchial secretion were immediately taken by the laboratory staff, and four of the laboratory assistants were suddenly taken ill within the next forty-eight hours.

The onset is sudden, with complaint of severe headache, dull, aching pains in the muscles and joints, general weakness and quite commonly dull pains in the lumbar region. Conjunctivitis is not infrequent in the initial stages. Sore throat is unusual. The patient takes to bed with chilly sensations, and the fever rises rapidly from 101 to 104 F. Early prostration is the rule. Epistaxis occurs in a considerable number of patients, in one person as much as a pint of bright red blood gushing from the nostrils. The pulse is accelerated and the respirations vary from 20 to 36 a minute. The second to the fourth day marks the critical period for the average patient. Remissions may occur, but among our cases more frequently following the crisis the temperature rises rapidly again and a slight bronchial cough develops, productive of small amounts of thick yellow or yellowish brown sputum teeming with gram-positive encapsulated pneumococci. There can be no doubt that the bronchial secretions are highly infectious at this time and that the disease is transmitted by personal contact and by droplet infection occasioned by coughing and sneezing.

Moreover, very early after the onset, careful physical examination of the patient's chest will often reveal scattered râles with areas of consolidation over the lower lobes and especially the right lower lobe. The bronchopneumonic process begins as an intense acute hemorrhagic tracheobronchitis, rapidly extending to the finer bronchioles of the lung. In the acute fulminating cases the patients become markedly cyanosed, and death results from an asphyxiative bronchiolitis with large quantities of frothy blood-tinged fluid exuding from the mouth and nostrils.

In the more protracted cases, particularly in civilian patients, the bronchopneumonia extends gradually to the left lower, and right middle and upper lobes, and clinical evidence of a severe toxemia manifests itself. Blood counts taken early after the onset of the initial symptoms exhibit a striking leukopenia as low as 1,800 per cubic millimeter, and averaging from 3,000 to 4,000 per cubic millimeter. With the onset of the pneumonia a definite leukocytosis quite commonly appears. The urine shows traces of albumin with hyaline and granular casts. Blood cultures taken early and late in the course of the disease and inoculated into glucose broth and plated in blood agar have remained uniformly sterile in forty-two instances.

MORBID ANATOMY

Of the first forty postmortem examinations made on the bodies of persons dying both early and late of bronchopneumonia, it was possible to obtain cultures from the nasopharynx, tonsils, washed selected bronchial sputum and from the lung parenchyma. Cultures were also obtained from these sites before death. The first eight necropsies were all of acute fulminating cases in young soldiers of excellent muscular development and physique. The course of the disease ranged from three to five days. Death was preceded by marked cyanosis and clinical evidence of acute asphyxiative bronchiolitis.

At necropsy the pleural cavities contained blood-tinged fluids remarkably free from fibrin content and varying from 300 to 1,000 c.c. in amount. The pleura of the lungs was fibrin free and regularly the seat of petechial and confluent hemorrhages. On cutting transversely across the trachea to reflect the viscera from the thoracic cavity, large quantities of blood-tinged, frothy fluid exuded from the air passages. The lining of the trachea and main bronchi presented a deep purplish red, and this intense inflammatory condition extended downward into the finest bronchioles. The consolidation was always lobular in type and involved most frequently the lower lobes, less often the entire midde and lower half of the right upper lobes. Marginal compensatory emphysema presented itself with striking regularity. The peribronchial lymph glands were acutely swollen and edematous. Cut surfaces of the lung presented a mottled, firm, granular appearance with intervening areas of dark red aerated lung tissue. Large quantities of bloody serum bathed the smooth, fibrin-free cut surfaces of the lung. The right heart was acutely dilated, in two instances the tricuspid valve ring measuring 13 and 14 cm., respectively, from cut edge to cut edge. In another body, bilateral symmetrical hemorrhage of rather huge dimensions was present in the tissues of the fatty capsules of both kidneys. The liver and kidneys were heavier than normal and the seat of fatty changes and parenchymatous degeneration. Passive hyperemia of the pia-arachnoidal vessels over the cerebral cortex, and edema of the leptomeninges were not uncommon. We desire to emphasize the fact that the amount of consolidated lung parenchyma was small as compared to the pneumonic consolidation quite regularly present in the more protracted cases among civilians. It will be noted that *B. influenzae* was isolated from only three of the lungs at necropsy in these eight early cases, in one instance in practically pure culture.

---

* From the Laboratory of Pathology of the Cook County Hospital.

In the more protracted cases among civilians the bronchopneumonic process presents a rather uniform bluish gray hue with the cut surface bathed in grayish yellow pus—a massive, confluent, pseudolobar pneumonia. Fibrin is frequently present over the pleura of the lower lobes of the lungs. In only one case was an empyema present. The hemolytic streptococcus was isolated in pure culture and identified in direct smears from the pus.

BACTERIOLOGIC FINDINGS

A careful detailed bacteriologic study of the prevailing epidemic, especially among the civilian population, forms the basis of this paper. Bacteriologic reports of the pandemic in Europe show that the influenza bacillus was found only exceptionally while pneumococci, streptococci and *Micrococcus catarrhalis* were recovered with considerable regularity from the sputum, nose and throat cultures. In Germany a circular letter addressed to the leading bacteriologists requesting the results of their laboratory investigations brought forth the following replies[1]: "Pfeiffer had not examined a sufficient number of cases at Breslau, but found his bacillus in some while failing to recover it from others, and was still investigating the causes of this discrepancy." Gruber in Munich and Friedmann in Berlin failed to find the influenza bacillus, and report streptococci and pneumococci as the common agents of the complicating pneumonias. Kolle in Frankfort failed to find *B. influenzae* in any of the cases which he had thoroughly examined.

Among the English observers, Gotch and Wittingham[2] isolated *Micrococcus catarrhalis*, with which they claim to have produced the disease in man. Little, Garofalo and Williams[3] found a gram-positive coccus which they believe to be the etiologic agent of the disease. From the Eastern States Keegan[4] in Massachusetts and Park[5] in New York have isolated the influenza bacillus in a high percentage of cases. These reports concern soldiers and sailors chiefly. Our study was made principally of the civilian population.

During the present epidemic in Chicago, more than 3,000 blood agar plate cultures have been made from swabs of the nasopharynx, tonsils and washed selected bronchial sputum and from the viscera and body fluids at necropsy in search for the influenza bacillus or other micro-organisms of possible etiologic significance. Blood agar plate cultures were made from the swabs of the nasopharynx and tonsils in more than 100 patients approximately equally divided into early and late cases. The washed bronchial secretions from the same patients were both plated and streaked on the surface of blood agar plates. Control cultures from the nose and throats of normal individuals were also made. In both groups a peculiar gram-positive coccus growing in grayish white colonies and exhibiting marked pleomorphism in stained smears was present with considerable frequency. The smaller coccal bodies passed Mandler filters in two instances. This coccus was nonpathogenic both for man and the ordinary laboratory animals.

TABLE 1.—PERCENTAGE INCIDENCE OF VARIOUS BACTERIA ISOLATED FROM THE SPUTUM, NASOPHARYNX AND TONSILS IN 100 CASES OF INFLUENZA

	Pneumococcus %	B. Influenzae %	Streptococcus Hemolyticus %	Staphylococcus %	Micrococcus Catarrhalis %	B. Mucosus-Capsulatus %	Miscellaneous
Washed bronchial sputum..	70	4	20	40	6	1	Diphtheroids 1%
Nasopharynx	38	0	4	65	6	1	Leptothrix 2% Meningococcus 2% Diphtheroids 1%
Tonsil.....	74	0	37	37	7	1	Diphtheroids 1%

In Table 1 is shown the percentage incidence of the various organisms isolated from the nose, throat and sputum of 100 patients. The influenza bacillus was recovered in four cases from the washed sputum—in three instances in predominating cultures, but always in symbiosis with staphylococci. It was not present in the nose or throat swabs. The predominating organism was the pneumococcus isolated from the washed sputum in 70 per cent. and from the throat in 74 per cent. of the cases. *Streptococcus hemolyticus* occurred in the washed sputum in 20 per cent., or twenty patients.

To determine how early and with what frequency the various bacteria invade the lungs, a series of lung punctures was made both before and after clinical evidence of pneumonia presented itself. A sterile needle attached to a glass syringe was passed through the intercostal spaces into the lung parenchyma, and lung tissue plus serum was aspirated sufficient to streak the surfaces of blood agar plates at the bedside. In addition, some of the aspirated material was inoculated into poured blood agar plates in each instance. Of thirty-six consecutive lung punctures taken during life, twenty-one were sterile. Eleven yielded the results given in Table 2. Thus the pneumococcus was present in pure culture in 72.6 per cent.; hemolytic streptococcus in 19.8 per cent., and *Micrococcus catarrhalis* in 6.6 per cent.

Table 3 gives the findings in cultures of the lung tissue streaked and plated on blood agar at necropsy. *B. influenzae* was isolated in three cases, or 8.7 per cent., in one instance in practically pure culture from both lungs. Again the predominating organism was the pneumococcus, occurring in 75 per cent. of the lungs at necropsy, from ten cases in pure culture, eleven times in predominating culture and in five instances in mixed culture. Of the various types of pneumococci recovered, Type II was present in 30.5 per cent. of the lungs, and Type IV in 50 per cent.

TABLE 2.—LUNG PUNCTURES DURING LIFE*

	No. of Cases	Per Cent.
Pneumococcus, Type I	1	6.6
Pneumococcus, Type II	2	13.2
Pneumococcus, Type III	3	19.8
Pneumococcus, Type IV	5	33.0
Hemolytic streptococcus	3	19.8
Micrococcus catarrhalis	1	6.6

* Incidence of the various bacteria isolated from fifteen lung punctures during life. Pneumococci predominated in pure culture in eleven cases, a total of 72.6 per cent.

TABLE 3.—LUNG CULTURES AT NECROPSY*

	No. of Cases	Per Cent.
Pneumococcus, Type I	2	7.6
Pneumococcus, Type II	8	30.5
Pneumococcus, Type III	3	11.5
Pneumococcus, Type IV	13	50.0
Influenza bacillus	3	8.7
Hemolytic streptococcus	15	43.0
Staphylococcus	18	40.0
Micrococcus catarrhalis	0	0.0

* Incidence of the various bacteria isolated from thirty-four lung cultures at necropsy. Pneumococci were recovered in pure culture in twenty-six patients, a total of 75 per cent.

TABLE 4.—NUMBER OF INSTANCES THE VARIOUS BACTERIA WERE ISOLATED FROM THE TISSUES AND BODY FLUIDS IN THE FIRST THIRTY-SIX NECROPSIES

	Pneumococcus	B. Influenzae	Streptococcus Hemolyticus	Micrococcus Catarrhalis	Staphylococcus
Heart's blood	7	0	8	0	0
Pleural fluid	15	0	8	0	2
Pericardial fluid	8	0	8	0	0
Tracheal mucosa	19	1	14	1	15
Lung	26	3	15	1	18
Spinal fluid	2	0	1	0	3
Peritoneal fluid	0	0	1	0	0
Middle ear	2	0	1	0	0
Frontal sinus	1	0	1	0	0
Spleen	0	0	3	0	4

The various strains of pneumococci were identified by morphology, cultural reactions, inulin fermenting properties, bile solubility and, finally, biologically with immune serums. Pneumococcus, Type IV, and allied green producing organisms were found to vary greatly both as regards bile solubility and inulin fermentation. Subsequent study of this heterogeneous group may extend it to include numerous strains of *Streptococcus viridans*. Hemolytic streptococci appear as late secondary invaders and were isolated from 43 per cent. of the lungs at necropsy. Staphylococci were frequently present.

THE INFLUENZA BACILLUS

It is evident from the tables that the influenza bacillus was isolated in only a relatively small percentage of the cases. Thus *B. influenzae* was present in four washed sputums—three times in predominating cultures growing typically as transparent minute colonies in symbiosis with staphylococci. It was recovered in one instance from the tracheal mucosa and three times from the lung cultures at necropsy. Influenza bacilli were never isolated from the lung punctures during life taken by preference from the early cases. On the other hand, the bacilli were recovered both in smears and in practically pure cultures from each lung in the case of a young soldier dying the fifth day of the disease. It appears that the Pfeiffer bacilli may have been the cause of the pneumonia in this case. In contrast to this single case we have not been able to isolate the bacillus in any considerable percentage of the civilian patients either during life or from acute fulminating cases at necropsy. The early results indicate that the technic employed should have sufficed to recover the organism if it were present in any considerable number of patients.

Furthermore, the high percentage of pneumococci obtained during life and at necropsy and predominating in the sputum, tracheal mucosa and lung tissue both early and late in the course of the disease suggest that this organism is at least the most important secondary invader and is responsible for many of the rapidly fatal pneumonias. It may be that we are dealing with a highly virulent strain of pneumococci sufficient in themselves to produce a rapidly fatal lobular pneumonia.

EXPERIMENTAL

Early in the course of our investigations we were impressed with the paucity of the bacteria in the nasopharynx at the onset of the disease and the marked degree of prostration exhibited in many of the patients. The possibility of a filtrable virus as the cause of the disease suggested the following experiments:

Experiment 1.—Oct. 2, 1918, the nose and throat of a patient having a typical case of influenza of forty-eight hours' duration was washed with 40 c.c. of sterile physiologic sodium chlorid solution, and the collected washings were diluted to a total bulk of 60 c.c. and shaken for twenty minutes in a sterile bottle containing glass beads. The fluid was immediately filtered through two small tested Mandler filters of medium porosity. The clear Filtrate A was inoculated into the anterior nares of three volunteers in amounts varying from 0.5 to 1 c.c. in each nostril. One of the men thus inoculated complained of slight headache, and presented a moderate conjunctivitis and a temperature of 99 F. twenty-four hours after the inoculation. These symptoms rapidly disappeared, and no further symptoms developed in any of the three subjects.

Experiment 2.—Oct. 4, 1918, the nasopharyngeal washings in two typical cases of influenza were mixed together and agitated in a sterile bottle containing glass beads for a period of fifteen minutes. The first patient had been ill only ten hours while the second patient was in the fifth day of the disease. The mixture of washings was immediately passed through a Mandler filter as Filtrate A and a second smaller portion filtered through a small Berkefeld candle N as Filtrate B. Filtrate A was inoculated into the anterior nares of two volunteers, and Filtrate B was similarly inoculated into the noses of two additional volunteers. One of the four subjects complained of a slight headache and presented himself twenty-four hours after the experiment with a definite coryza, conjunctivitis and lacrimation. These symptoms had completely disappeared by the following morning, and the men had all remained well when seen two weeks later. Cultures of the clear filtrates were inoculated into glucose broth and in the anaerobic tissue ascitic fluid culture medium of Noguchi. All tubes remained sterile after the expiration of two weeks. From these observations, which confirm those recently reported by Keegan, it may be assumed that the etiologic agent is not filtrable.

Experiment 3.—Oct. 4, 1918, at 4 p. m., the trachea and main bronchi secured at necropsy from a patient dying on the fifth day of the disease was split parallel to its lumen and the swollen dark red mucosa curetted off and thoroughly ground up with sterile sand in a mortar to make a turbid suspension in 50 c.c. of sterile saline solution. The suspension was centrifuged at slow speed to throw down the gross particles, and half of the resulting red emulsion was passed through a Mandler diatomaceous earth candle of 12 pounds positive pressure. A *Macacus rhesus* monkey received 5 c.c. of the unfiltered suspension in each nostril, and 20 c.c. of the clear filtrate were injected at the same time very slowly intravenously. No symptoms developed.

Experiment 4.—Oct. 8, 1918, the monkey received 2 c.c. of the mixture of the nasopharyngeal washings in four early cases of influenza in each nostril after previous swabbing and washing out the protective mucus in the nares. No symptoms developed after seven days' observation.

COMPLICATIONS AND SEQUELAE

During the past five weeks of the present epidemic there were eighty-six pregnant women admitted to the obstetric wards of the hospital affected with influenza or pneumonia. Of this number twenty-one died shortly after miscarriage. Twenty additional deaths occurred before miscarriage could result, and forty-five patients recovered with or without miscarriage. The total maternal mortality has been 45.5 per cent.

Among other complications of the disease, eleven patients have developed a unilateral or bilateral purulent otitis media. Pure cultures of pneumococci were isolated from eight discharging ears, the hemolytic streptococcus in two patients and the *Streptococcus viridans* in the remaining case. One child developed an acute and fatal mastoiditis. Purulent frontal sinusitis was encountered in one instance at necropsy, and cultures yielded pure hemolytic streptococci. It is to be expected that sequelae of still more diverse nature may subsequently develop.

SUMMARY

A severe and rapidly spreading epidemic of influenza and bronchopneumonia first appeared at the Cook County Hospital, September 23. During the past five weeks more than 2,000 patients were admitted to the hospital. The disease is highly contagious, and the mortality among our patients has totaled 31 per cent. The epidemic has seriously crippled the medical and more especially the nursing staff of the hospital. More than fifty of the nurses and twelve of the physicians have contracted the disease, three deaths occurring among the total number.

The influenza bacillus was isolated in only 8.7 per cent. of the total cases and chiefly from a small number of soldiers. In one instance it appears that the influenza bacillus may have caused the fatal bronchonpneumonia. Influenza bacilli were isolated only exceptionally from the civilian patients. Pneumococci were the predominating organisms in the sputum, throat cultures and in the lung cultures both during life and at necropsy. Pneumococci of unusual virulence were the most important early secondary invaders, and have sufficed to cause many of the fatal pneumonias.

Experiments indicate that the disease is apparently not due to a filtrable virus.

Liability for Performing Unauthorized Postmortem Examination.—It is held in the Minnesota case of *Woods* v. *Graham*, 167 N. W. 113, annotated in L. R. A. 1918 D, 403, to be no defense to an action to recover damages caused by a necropsy performed on the body of the daughter of plaintiff, without the consent of the next of kin, that defendant, as the attending physician, was unable to ascertain the cause of death and performed the necropsy for that purpose, so as to be able to give a certificate, as required by law, stating the cause of death.—*Legal Notes.*

INCORRECTNESS OF THE DIAGNOSIS OF DEATH FROM INFLUENZA

PRESENCE OF BRONCHOPNEUMONIA IN PRACTICALLY ALL PERSONS SEVERELY ILL WITH INFLUENZA *

HENRY A. CHRISTIAN, M.D.
Hersey Professor of the Theory and Practice of Physic, Medical School of Harvard University; Physician-in-Chief, the Peter Bent Brigham Hospital
BOSTON

Boards of health, as indicated by newspaper reports, very generally are subdividing their mortality reports from epidemic influenza into deaths from influenza and deaths from pneumonia or bronchopneumonia. This is no doubt based on the death certificate return handed in by the physician in charge of the patient. Is it a correct return? In my opinion it is not. The correct return should be bronchopneumonia and (epidemic) influenza. Whether the bronchopneumonia is part of the influenza or is a complication of that disease; whether the disease is due primarily to the influenza bacillus; whether the pulmonary consolidation is caused primarily by the *Bacillus influenzae* or is the result of concomitant bacteria are questions that cannot be answered on the basis of our present information. However, my own observations on patients suffering from epidemic influenza do justify a vigorous protest against a statistical subdivision of death reports into those dying from influenza without pneumonia and those dying from bronchopneumonia or pneumonia and influenza.

My reasons for believing that in practically all fatal cases of epidemic influenza there is a pneumonic process in the lungs before death are as follows:

1. In 126 consecutive fatal cases of epidemic influenza observed by me and my assistants at the Peter Bent Brigham Hospital, not a single patient failed to show physical signs justifying a clinical antemortem diagnosis of bronchopneumonia.
2. In twenty-two consecutive necropsies at the Peter Bent Brigham Hospital in fatal cases of this group, no single case failed to show pathologic changes in the lung justifying the diagnosis on the part of the pathologist of bronchopneumonia.
3. In patients submitted to necropsy, pulmonary changes are as a rule more extensive than physical signs during life had indicated.
4. Clinical study of nonfatal cases of epidemic influenza justify the belief that with very few exceptions, patients with fairly severe to severe cases have bronchopneumonia.

In making the foregoing statements I do not deny that influenza patients may die from an overwhelming toxemia without pulmonary involvement or from influenzal meningitis or encephalitis or from some other manifestations of the disease. Such fatal cases did not occur at the Peter Bent Brigham Hospital, and in conversation with my colleagues who have had postmortem experience in this disease I have found that their views have seemed to coincide with those expressed here by me. In our admissions to the hospital of patients sent in with the diagnosis of influenza, I have seen cases of meningitis; one case was due to the meningococcus and apparently did not have any complicating influenza; two patients were tuberculous and may have had influenza, and two cases were due to the pneumococcus in influenza patients with pneumonia. Several patients with influenza and having signs and symptoms suggestive of meningitis showed spinal fluids with normal cell counts and negative cultures. No spinal fluids in our cases showed *B. influenzae*.

---

* From the Medical Clinic of the Peter Bent Brigham Hospital.

The statement made under No. 4 is based on these facts. In 195 unselected cases[1] of epidemic influenza studied in the wards of the Peter Bent Brigham Hospital, 132 showed during their period of observation in the hospital sufficient physical signs to justify the clinical diagnosis of bronchopneumonia. The 132 include practically all severely ill patients and many who were only mildly ill. The only patients in whom the temperature was as high as 101 for more than three days in this series in which no diagnosis of bronchopneumonia was made were fourteen in number. Two of these had complicating otitis media, and one was an asthmatic with chronic bronchitis antedating influenza; eight were patients admitted on the day of their first symptoms, two on the third day of their disease, and one on the fourth day. Of these last eleven patients, none were more than mildly ill, and they appeared to be free of any complications.

The physical signs on which was based the diagnosis of bronchopneumonia were areas of bronchial breathing or consonating râles, usually both, frequently bronchophony and often dulness on percussion. The occurrence of any one of these signs in a localized area appears to justify the diagnosis of bronchopneumonia. In a number of our patients, roentgen-ray examinations were made and invariably showed evidence of consolidation where these physical signs had been observed. Moreover, the roentgen plate as a rule showed more extensive areas of consolidation than clinical signs indicated; and not infrequently it showed consolidation before we had felt justified in diagnosing it on the basis of physical signs. The peculiar snapping consonating quality of the râle in epidemic influenza seems of great significance as indicating consolidation. All who have been listening to the chest in influenza patients will, I am sure, recognize what I mean, though my word picture of the quality of the sound is very inadequate.

The early foci of consolidation in influenza are found almost invariably in the region of the angle of the scapula and the interscapular regions. Here the roentgen ray shows that consolidation begins, i. e., toward the inner lower border of the lung posteriorly rather than anteriorly. From such an early beginning, rapid spread often takes place, leading to very extensive diffuse consolidation and not infrequently giving the clinical picture of a lobar pneumonia, though I believe true lobar pneumonia is really rare in association with influenza.

If the busy clinician—and never were our medical men so overwhelmed with work as in this epidemic—will percuss rapidly the lower lobes in the back and listen in the region of the angle of the scapulae and next in the interscapular regions he will find quickly in most severe cases evidence justifying him in diagnosing bronchopneumonia. Of course, in many cases further examination will yield evidence of much more extensive pneumonic involvement.

I should not be justified in making the extreme statement that all patients with epidemic influenza have bronchopneumonia. Many milder cases certainly give no physical signs of consolidation, and the roentgen ray shows no shadow sufficient to justify the diagnosis of a focus of consolidation. I believe, however, that we are justified in regarding epidemic influenza as a disease involving the respiratory tract and except in the milder cases causing a clinically demonstrable bronchitis and bronchopneumonia in the larger proportion of cases. That as the severity and duration of the disease increases the percentage of patients with bronchopneumonia increases, and that in fatal cases almost without exception bronchopneumonia is present, are conclusions which seem fully justified by the data here presented. A corollary to this is that, in my opinion, it is quite incorrect to consider fatalities in this epidemic as due to influenza uncomplicated by bronchopneumonia except in such exceptional cases as to form a negligible factor in statistical reports of death returns.

AN EPIDEMIC OF INFLUENZA AT MANILA, P. I.*

A. FRANCIS COUTANT, M.A., M.D.
Chief Surgeon, Hospital Ship
ZAMBOANGA, P. I.

During the month of June, 1918, an epidemic of influenza appeared in the Philippine Islands which presented a number of interesting manifestations. At the time I was in charge of St. Luke's, one of the most popular hospitals in Manila, and will attempt to summarize my notes and records during that period. About 300 cases, the majority of which were hospital patients, came under direct observation.

The epidemic, so far as can be determined, began in Manila, although the fact that cases were first noted among longshoremen and other laborers along the waterfront might indicate that it had been brought in from some other part of the world. On the other hand, the statements of Castellani and Chalmers and others that pandemics of influenza have usually started in the Far East further the belief that this epidemic originated here. All of the reports and rumors of influenza occurring elsewhere—in other parts of the Philippine Archipelago, in Japan, Vladivostok, Spain, etc.—that have come to my attention have placed their outbreaks at later dates than the one at Manila, with one exception: Between thirty and forty cases of influenza, with at least one death, occurred on a United States Army transport which left San Francisco shortly before the epidemic appeared in Manila, and arrived here after it was practically over. The Filipino cabin-boys and mess attendants were the most seriously affected on board the transport, although several first-class passengers were also ill.

While the disease in the Manila epidemic affected all classes and races, it was most severe among the Filipinos, less so among the Chinese and Japanese, and still less among the Europeans and Americans. As there was no attempt at isolation, the infection spread rapidly. Within three days after the first cases were noticed, between 70 and 80 per cent. of the longshoremen, clerks and other workers at the docks were unable to work, with the result that several of the transpacific vessels were delayed in sailing. In two days more, the epidemic had reached the business and residence sections of the city. In one large business firm, 80 per cent. of the native employees were away from work for at least two days, while 50 per cent. of the Europeans were absent for one day. The majority of the business concerns were similarly incapacitated. Two of the newspapers were so crippled that publication was suspended for a day, and the telephone company asked the indulgence of the public for its poor service, explaining that 90 per cent. of its force was suffering from the epidemic.

---

[1] This represents only those patients discharged and having their histories completed and filed in the record room to date. The total of our cases, about 500 in number, will show somewhat the same rates.

* The observations on which this note is based were made under the auspices of the International Health Board of the Rockefeller Foundation.

St. Luke's Hospital, with a normal capacity of seventy patients, accommodated between ninety and ninety-six for several days, the largest number admitted in its history. The work necessitated by this increase was accomplished with great difficulty, as one third of the nursing staff and one half of the orderlies and attendants were ill.

Within ten days after the initial outbreak the great majority of those who had been ill were well enough to be back at work, and business and industrial activities resumed their normal course. However, the hospital continued to be overcrowded with cases diagnosed as influenza for two or three weeks more, and it was not until the advent of a typhoon, which brought with it a great deal of wind and rain, that the last vestiges of the disease were swept away. During the epidemic there was no apparent decrease in the number of admissions to the hospital for other diseases.

Clinically, most of the cases ran the typical course of influenza as described in textbooks, namely, sharp onset, usually with sore throat or upper respiratory tract symptoms, sudden high fever, and headache, with aching and stiffness all over the body. A pronouncedly slow pulse rate, in proportion to the temperature, was remarked to be the rule. This slow pulse, and the absence of a skin rash, together with the lightning-like spread of the epidemic, served to differentiate the disease from dengue fever, the only closely similar condition. The highest temperature recorded was 106.2 F. The patient with this high fever did not suffer, however, nearly as much as many others, and it appeared that the severity of the attack did not depend on the temperature. The majority of the patients also withstood the pain very well, as is the usual thing among these peoples, but the toxemia developed was so great that it made those who were most severely stricken practically collapse. The faces of the patients as a whole, as one looked down the wards, were more miserable-looking during the days of the epidemic than at any other time in my experience.

Of the more unusual features of the disease, it may be mentioned that anorexia, nausea and vomiting were much more common than usual. In 8 per cent. of the hospital cases, repeated emesis was noted. One patient came to the hospital for hiccups which had commenced on the second day of the disease, and had persisted continuously for forty hours before admission. Hemorrhage from the mucous membranes was a fairly prominent feature. Epistaxis occurred in 1 per cent. of the cases, and coughing up of blood from the lower respiratory passages in 1.5 per cent. Two patients vomited fresh blood in small amounts, and four passed noticeable amounts of fairly fresh blood by rectum. There were neither hemorrhoids nor symptoms of dysentery in the latter cases, and there was no evidence of tuberculosis in the cases in which the hemoptysis occurred.

The patients were all given a routine course of treatment, consisting of calomel and santonin followed by Epsom salt or castor oil, quinin, and occasionally acetylsalicylic acid for headache.

The death rate for the patients admitted to the hospital was very high for this disease, 2 per cent. instead of the usual 0.4 to 0.6 per cent. As one would expect, the mortality rate in the hospital was higher than in the city at large, although thirty-one deaths were reported to the bureau of health during the short period of the epidemic.

All of the patients dying in the hospital developed symptoms of pneumonia, and in one case in which a necropsy was performed, a large very foul-smelling abscess was found in the upper left lobe, while the lower left lobe was in the stage of red hepatization.

There is no question in the minds of the clinicians of Manila that this epidemic was influenza or the grip, but the following personal communication from Dr. J. W. Johnson, M. R. C., U. S. Army, shows that the causative agent was undoubtedly *Bacillus influenzae* of Pfeiffer:

> The organism found was small, about 0.5 micron in length by 0.3 micron in width, and had rounded ends. Staining with Loeffler's methylene blue gave best results, allowing the stain to act for not less than five minutes. The organism was gram-negative, and staining by this method had a tendency to be irregular. Blood agar (human blood) or agar streaked with fresh human blood gave best results as a culture medium. Small portions of sputum were picked up with sterile forceps, washed in sterile distilled water, and rubbed over blood agar plates or slants, and these were incubated at 37.5 C. Colonies appeared in about twenty-four hours as very minute transparent droplets, like dew drops, and gave the appearance of frosted glass. Cultures soon died out, and it was found that transplanting every two or three days was necessary. Even then, after three or four subcultures, growth ceased. The organism was recovered from the very first patients who clinically developed the disease. Cultures from the blood remained sterile.

CONCLUSION

An epidemic of the severe or epidemic type of influenza occurred in the Philippines in June, 1918, apparently spontaneous in origin. It was of more than usual severity, especially among the native peoples, and affected a larger proportion of the whole population than is the rule. Although at present we have no definite information that the epidemic has spread farther than to southern Japan, it is easy to imagine that this may be the beginning of another pandemic of the disease. It is highly desirable, therefore, that epidemics in other localities in the near future be promptly recognized and reported, so that the direction of travel and rapidity of dissemination of the disease may be learned. Should a pandemic be approaching the battle fronts, every effort will be necessary to prevent it from actually reaching and playing havoc in the Allied armies.

Complement Fixation Test for Syphilis.—In *Public Health Reports*, Aug. 23, 1918, M. H. Neill of the Public Health Service describes the method of performing the complement fixation test for syphilis as now used in the Hygienic Laboratory of the United States Public Health Service. It is a modification of the Wassermann test and the description is full and complete, with a list of the apparatus and reagents required.

THE MORPHOLOGY OF THE INFLUENZA BACILLUS *

GLADYS HENRY DICK, M.D.
AND
ELEANOR MURRAY
CHICAGO

Pfeiffer[1] described a "true influenza" bacillus and a "pseudo-influenza bacillus." He was unable to distinguish these organisms in direct smears of exudates, where they both appeared as small bacilli with rounded ends. Culturally they were identical. He based his distinction on the fact that smears from cultures of the true influenza bacillus showed small bacilli with few longer forms, while smears made from cultures of the pseudo-influenza bacillus showed long, threadlike organisms. The pseudo-influenza bacillus was isolated by Pfeiffer from three cases of bronchopneumonia.

In bacteriologic examinations of the sputum, blood and lungs during the present epidemic of influenza, both forms of the influenza bacillus have been encountered. In some cases aerobic plates of the sputum have yielded practically pure cultures of the small gram-negative bacillus contaminated only by rare colonies of staphylococcus. Sputum from other cases has yielded equally pure cultures of the long, threadlike organism designated by Pfeiffer as pseudo-influenza bacillus.

This long, threadlike form appeared in the blood culture of a patient whose sputum contained the same type of organism. Aerobic plate cultures of the pneumonic area in a lung showed a pure culture of an organism which at the end of twenty-four hours' growth appeared in smears as a very small, gram-negative bacillus, and at the end of forty-eight hours, as long, wavy or curled, gram-negative threads which would ordinarily be classed as a leptothrix. In every case direct smears of the sputum showed only the small, bacillary form.

These findings suggested that however unlike the two forms appeared in smears made from cultures, there was a possibility that they were the same organism.

In order to determine if the reaction of the medium influenced the morphology of the organism, medium was prepared by adding human blood to a series of tubes containing agar which, after sterilization, titrated 1.5, 1.0, 0.4, 0.2 acid, neutral, 0.2, and 0.7 alkaline expressed in percentages of normal sodium hydroxid with phenolphthalein as an indicator. Seven sets of these tubes were inoculated with different strains of organisms. Four of the strains used were small bacilli, such as Pfeiffer termed true influenza. Three were the threadlike forms which he considered pseudo-influenza bacilli. Smears were made from the tubes at the end of twenty-four and forty-eight hours.

The three strains that resembled leptothrix in the original cultures still showed the long threads in the more acid medium, but on the 0.2 acid and neutral tubes they grew as small bacilli which could not be distinguished from true influenza bacilli. The four strains that grew in the original cultures as small bacilli showed transitions from the longer, sometimes threadlike forms on the more acid medium to the small bacillary forms on the slightly acid and neutral tubes.

Kato[2] reported a gram-negative leptothrix which he believed to be the cause of pleuropneumonia. In a bacteriologic study of the pneumonia occurring at Camp Pike last winter, Dick[3] found leptothrix organisms predominating on plates of the sputum in 6 per cent. of the cases. He described them as "very minute colonies, barely visible to the naked eye, but extremely numerous. There was no effect on blood. The organisms were gram-negative and varied in length from organisms resembling influenza bacilli, to long, slightly wavy organisms extending half way across the field. It was not possible to cultivate these organisms beyond one or two subcultures, and their importance is undetermined."

Where there is such variation in morphology in different cultures of the same strain, it does not seem justifiable to classify influenza bacilli as true and pseudo on the basis of morphology alone. In attempting to isolate influenza bacilli, it is important to recognize the leptothrix-like form as well as the small bacillary form.

NOTES ON THE PRESENT EPIDEMIC OF RESPIRATORY DISEASE *

SOLOMON STROUSE, M.D., AND LEON BLOCH, M.D.
Attending Physician and Associate Attending Physician, Respectively, Michael Reese Hospital
CHICAGO

From September 20 to October 31, we saw both in our services at the Michael Reese Hospital and in private practice approximately 500 cases of epidemic respiratory disease. The various forms of onset will easily fall into three groups: the first characterized by symptoms of a more or less severe coryza, the second by varying degrees of prostration, backache, headache, chilly sensations and elevated temperature, and the third by a feeling of indefinite discomfort, with no fever, but in a few hours a definite rise of temperature. Careful examination at the beginning of the disease, in all cases, usually revealed few signs, except for a slight reddening of the anterior pillars of the pharynx, and in many instances an intense congestion of the conjunctivae. Many patients who were coughing violently showed no signs of bronchial involvement, the cough probably being due to an intense congestion of the trachea. However, in a large percentage of our cases, careful examination at the onset showed a more or less circumscribed area, sometimes no larger than the bell of a stethoscope, which would manifest râles or dulness or changes in the breath sounds. It is our opinion that all these cases should be considered pneumonia, as a large percentage of this type does not show the drop to normal in three or four days.

DANGER OF PULMONARY SIGNS

One of the most important lessons learned from the epidemic is the potential danger residing in these small pulmonary signs, even when the temperature is normal. In several of our cases, a very slight pulmonary condition, after careless exposure to cold, developed into severe pneumonia. The development of pneumonic symptoms in these patients occurred either (*1*) after a complete defervescence, following on the footsteps of a more or less severe febrile period, lasting from one to two days; (2) after a drop in temperature, but not to normal, or (3) without a reduction, but instead with an elevation of the temperature on the third or fourth day. In any one of these three forms, the physical signs of bronchopneumonia would be present at the beginning of this phase of the disease, or would appear within a day or two. It is our opinion that the persistence or appearance of a rise in temperature on the third day indicates bronchopneumonia.

---

* From the Medical Service of the Michael Reese Hospital.

The appearance of the patient early in the disease does not betray his condition. Aside from the conjunctivitis and mild pharyngitis, already mentioned, the patient does not appear ill. Later, however, with the advance in the pneumonic process and an increase in the toxemia, cyanosis, sometimes with more or less edema of the face, becomes prominent. Stupor, restlessness and delirium may appear. At times, the uncanny combination of absence of the radial pulse, profuse perspiration and cyanosis, with the patient in full possession of his mental faculties, indicates only too clearly the fatal termination. The low pulse rate, which has been so characteristic of the disease, is a definite sign. Patients seen early with a pulse rate above 100 always evoke a suspicion of some other disease, although occasionally an increased pulse rate may have been caused by too large doses of acetylsalicylic acid. Late in the disease, with an increase in the severity of the condition, a rapid pulse rate is present. One rather striking feature was the inverted type of temperature. Many of our patients would be normal except at 4 or 8 a. m. The combination of the slow pulse, with this inverted type of temperature, sometimes made the diagnosis of influenza, when otherwise the diagnosis would have been difficult to establish.

Perhaps the most common site of the pneumonic disturbance was in the left lower lung, posteriorly, although no portion of the lung was particularly exempt, and no particular site had any special prognostic value. The type of pulmonary pathologic condition varied clinically from the small patch, which ordinarily would be considered merely a bronchitis, to a large massive pneumonia, with general edema of both lungs, and expectoration of bright red blood.

RESPIRATORY RATE

The respiratory rate early was as a rule slow, even though the temperature and pulse rate were increased. The appearance of an increased respiratory rate, from 40 to 50, indicated not only an increase in pulmonary involvement, but what seemed of more significance, an increase in toxemia. At times a definite air hunger, suggestive of a severe acidosis, made its appearance. From our experience, we have come to look on an increased respiratory rate, even though the temperature and pulse did not become elevated, as of more unfavorable significance than almost any other sign. On the contrary, when the temperature was high and the respiratory rate low, the condition was not considered unfavorable.

COUGH AND EXPECTORATION

Cough was a prominent and troublesome symptom in the majority of cases. Generally unproductive at the onset, later it became painful and accompanied by nummular expectoration and abdominal pain, probably muscular, from the strain of coughing. Where bloody expectoration occurred, the cough was not so frequently accompanied by pain.

PLEURITIC PAIN

Actual pleuritic pain, either thoracic or referred abdominal, occurred in a small percentage of cases. In these cases a pleuritic friction rub could be heard. Fluid in the chest, either serofibrinous, bloody or purulent, occurred, more frequently later in the epidemic than at the beginning. The removal of the fluid except in cases of empyema even in small amounts, by exploratory thoracentesis, seems to be followed by definitely favorable changes in the course. Involvement of the accessory sinuses of the nose is probably very common, and a routine examination ought to be established to rule this out. Ear infections, which were so common in the epidemic of 1891, were comparatively rare at the beginning of the epidemic, but apparently are becoming more prominent as late sequelae.

BLOOD PRESSURE

There was a normal or slightly diminished systolic blood pressure in those patients in whom the disease ran a moderate course. The diastolic pressure, however, was considerably lower than was to be expected. A systolic pressure of 100, with a diastolic pressure of 40, was a not uncommon occurrence. When the diastolic pressure was high or comparatively high, some cause was to be found, as a nephritis. One patient whose systolic pressure was 120, diastolic 85, with Cheyne-Stokes breathing during her pneumonic phase, had a systolic pressure of 180, and diastolic of 115 on recovery from the pneumonia. In no case, except when an organic heart lesion had previously existed, was there found a dilated right heart indicative of cardiac failure.

MENSTRUATION

In the women practically all menstruated between the first and third day of the disease, and many of these patients had considerable menstrual difficulty in the period following the disease. It is too early yet to speak definitely on this subject. Many women had considerable difficulty in urination at the beginning of the disease. Anuria of from twelve to twenty hours was not uncommon, so that catheterization had to be resorted to on account of a large urinary bladder tumor. Albumin and casts were found frequently in the later stages of the disease. Intense headache, rigidity of the neck and back, with spinal fluid under high pressure, suggested meningitis. However, cytologic and chemical study of the spinal fluid yielded negative results. The patient made an uneventful recovery.

Although one hears considerable of gastro-intestinal influenza, the large majority of the patients do not have gastro-intestinal symptoms, except when they are severely ill, when nausea, vomiting, and complete anorexia may set in. Many patients, however, complained of intense abdominal pain, which was apparently due to a muscular disturbance from the violent coughing. In the later stages of the epidemic, and likewise perhaps two or three weeks before the epidemic reached Chicago, we saw a number of cases of acute gastro-enteritis which may or may not have been associated with the epidemic. In many instances, the clinical picture was similar except for the location of the disease.

BACTERIOLOGIC FINDINGS

The accompanying table (1) shows clearly the incidence of positive bacterial findings. Positive blood cultures were without prognostic significance. A leukopenia was the rule, except when an empyema developed. In these cases, a leukocytosis from 10,000 to 18,000 obtained.

We had a number of cases complicating other diseases, and strangely enough these patients were apparently no worse off than others. We had three cases complicated by bronchial asthma, one with a massive pneumonia, and another in which the patient was not so severely ill; all made uneventful recoveries. At least one case, and perhaps more, occurred on top of an old pulmonary tuberculosis. Several patients had organic heart disease, and none of these died. Two cases complicated chronic nephritis; one patient made uneventful recovery and one died.

* This table was kindly prepared by Dr. Katherine Howell, who will later make a detailed report of her studies.

PREGNANCY AS A COMPLICATION

Perhaps the saddest feature of the whole epidemic was the effect on pregnant women or women with very young children. These cases were unquestionably the most severe in our experience, and many of these patients died. At present it is impossible to collect our statistics. These patients very early became markedly cyanotic, dyspneic, had rapid pulse, and massive (often hemorrhagic) pneumonia, and many of them from the first day of the illness gave an absolutely unfavorable prognosis. One patient in particular, a healthy young woman with two children, seen early in the epidemic, was moribund in twenty-four hours from the onset.

CLINICAL COURSE

The clinical course ranged from a few days to two weeks of acute symptoms. The distressing feature in many cases was that when the patient seemed to be progressing favorably toward an uneventful recovery, suddenly like lightning from a clear sky he would develop an increasing cyanosis, high temperature, high pulse and respiratory rate, a severe toxemia and pass away in from twelve to thirty-six hours. Relapses did not occur, although in two instances that came to our notice, patients died one week later from what appeared to be pulmonary embolism.

Convalescence was often very greatly prolonged, so that at times two or three weeks were required before the patient felt well enough to be up and about.

PROGNOSIS

No disease has ever been encountered in which it was more difficult to outline a prognosis. Patients, apparently mildly ill, suddenly on the third or fourth day would show a high temperature, cyanosis, rapid respiration and pneumonic consolidation, and would rapidly get worse. On the other hand, quite a number of our cases, especially those seen in the hospital, with cyanosis, lobar pneumonia and extremely toxic symptoms, pulled through to uneventful recoveries, without any special line of treatment. All the cases that were not complicated by pneumonia offer an absolutely good prognosis, but we had to be extremely cautious in all the pneumonic cases. Some factors which we considered of importance for prognosis are immediate taking to bed and keeping warm, with plenty of fresh air in the room and proper bedside care. By proper bedside care we mean absolute bed rest, the patient not being allowed to leave his bed for any purpose whatsoever. In several apparently mild cases pneumonia developed when the patient got up too soon, and it is our opinion that a certain percentage of the mortality from the epidemic might be prevented. Some patients die, no matter how excellent the care they obtain; but such a large proportion of the deaths occurred in patients apparently well who suddenly develop pneumonia, after exposure, that the impression of cause and effect is very definitely produced.

MORTALITY

The hospital statistics for the month of October show 269 admissions of all types, including moribund pneumonia patients. Of this number, forty-seven, or 17 per cent., died, but eleven of the forty-seven were in the hospital less than twenty-four hours, reducing the mortality to 13.4 per cent. From the hospital personnel of approximately 400 there were 107 admissions, of whom three, or 2.8 per cent., died.

TREATMENT

Prophylactic vaccination is as yet of unknown value. We know of at least three instances in which three doses of a vaccine had been given and influenza subsequently developed, and of over twenty instances in which one or two doses had been given, followed later by typical attacks of influenza and pneumonia.

We feel definitely that at present there is no special treatment. The two of us, working on independent services, gradually evolved an identical plan of practically leaving the patient alone and treating symptoms as they arose. We have used acetylsalicylic acid, 10 grains, or powder of ipecac and opium (Dover's powder) 10 grains, or both, with hot alkaline drinks and purgation for the first two days; then if there were any evidences of pneumonia, medication was removed and the patient treated purely for his symptoms. Heroin or morphin were found to be the best sedatives for the violent coughing and to keep the patient in comfort. We found that the administration of large quantities of fluids of all kinds by mouth, and when not retained, by rectum, either as plain tap water or with the addition of glucose, in 5 per cent. solution, and of urging the patient to take as much food as possible, with plenty of fresh air and warm coverings, were the most important factors in the treatment.

Early in the epidemic, we found that the administration of expectorants, salicylates, hexamethylenamin, quinin, etc., were of little value. Hexamethylenamin seems definitely contraindicated because of its tendency to produce hematuria. Cardiac stimulants, as digitalis, caffein and sodium benzoate, by mouth or hypodermically, were used, but with questionable value. Camphor in oil, pituitary solution in 7 minim doses, epinephrin in physiologic sodium chlorid solution by hypodermoclysis, and atropin in 1/60 to 1/100 grain doses, especially when an edema of the lungs was imminent, did not seem to alter the course of the disease. Whisky, brandy and aromatic spirit of ammonia were all used, but except for a temporary stimulation seemed useless. Champagne served in teaspoonful doses, with ice pellets, was sometimes the only thing the severely ill patients could tolerate without nausea. Oxygen by inhalation relieved the cyanosis, but had no effect on the course.

Convalescent serum (400 c.c.) was administered in one case, without preventing a fatal termination.

CONTAGIOUSNESS

A word as to the element of contagion. All of the interns who became ill had been in close contact with the patients, and many of the nurses who attended influenza patients subsequently became patients themselves, despite the fact that they took precautions to wear face masks while on duty taking care of patients, and to wash their hands in antiseptic solutions before leaving their patients. The air in one of the wards, on culture, yielded the hemolytic streptococcus.

CONCLUSIONS

1. The present epidemic of "influenza" or "influenzal bronchopneumonia" or "epidemic pneumonia" is as yet of unknown etiology.
2. The course of the disease, apparently mild at first, is treacherous, and not associated with any symptoms that might indicate the intensity or the severity.
3. In our hands no specific treatment seemed to have greater value than the induction of symptomatic relief, which we believe should be the hub of the treatment.

TWO CASES OF HUMAN ANTHRAX AT CAMP JACKSON [*]

OSCAR T. SCHULTZ, M.D. (Chicago)
Captain, M. C., U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

Anthrax, a disease of relatively rare occurrence in civil life in this country, has assumed a certain degree of importance because of scattered cases that have appeared in Army camps. A few cases have occurred in camps in this country, and in the British army the cases have been more numerous. Usually it is possible to trace the infection to contaminated shaving brushes. The occurrence of two cases in Camp Jackson within a very short period of each other, the first reported from this camp, appears worthy of record, especially in view of the fact that the first case was so atypical clinically that the nature of the condition could not be suspected without the laboratory findings.

REPORTS OF CASES

Case 1.—*Clinical Course.*—A private of the One Hundred and Fifty-Sixth Depot Brigade, white, aged 23, was admitted to the base hospital, July 17, 1918. The family and previous history were negative. July 14, while shaving, he noticed a small pimple on the neck. He squeezed out a small amount of fluid; the lesion began to swell and grew worse from this time. By July 16 the swelling had extended well down on the chest. On admission both sides of the neck were swollen, the swelling extending downward on the chest to 1 inch below the nipple line. There was a small abrasion on the left side of the neck anteriorly. The pulse was weak, the skin was somewhat cyanosed, and respiration was sighing in character. The temperature on admission was 97.2, the pulse 124, respiration 26. The white blood cells numbered 16,500, of which 78 per cent. were neutrophils, 2 per cent. basophils, 13 per cent. small mononuclears, 5 per cent. large mononuclears, and 2 per cent. transitionals. The diagnosis made at this time was cellulitis of the neck. The patient's condition rapidly became worse. At 3 p. m. of the day of admission the swollen tissue was incised and drained, the incision consisting of a 4 inch median longitudinal incision, with a 4 inch subclavicular incision at each side. No pus was present. The incised tissue was edematous. Smears and cultures were made from the fluid that exuded from the incision. A blood culture was taken on the evening of the day of admission; the blood at this time was very thick and dark and coagulated quickly. When the dressing was changed at 3:30 a. m. of the next day a large amount of serum was present, and the swelling of the chest had decreased slightly. The patient appeared very ill. Examination of the cultures made from the incision and of the blood culture showed the presence of *B. anthracis*. At 9 a. m., July 18, the dressing was changed again, a large amount of serum being present. The patient failed rapidly and died at noon, July 18.

Necropsy.—This was done four hours after death. In the region of the upper chest was an open crucial incision that extended through the skin and soft parts to the underlying bone. The longitudinal limb of the incision extended from the sternal notch to the middle region of the sternum. The horizontal limb extended from the middle of the left clavicle to the middle of the right clavicle. The margins of the incision were retracted, and the exposed tissue was found to be covered by a thin layer of grayish white material. Slightly to the left of the midline of the neck and 5 cm. above the clavicular line was an oval superficial skin lesion, 0.5 by 1 cm., covered with a dark crust. The neck was swollen, the swelling extending laterally on each side to the line of the mastoid region. The skin of the swollen region was slightly reddened and felt boggy. The cervical glands were not palpable. In the inferior chest region, below the lower end of the longitudinal incision, the subcutaneous tissue was edematous and gelatinous. The loose tissue of the upper anterior mediastinum was edematous. The spleen was increased in size to about four times the normal. The capsule was tense, free of adhesions, and bluish. The tissue on section was dark red and moderately firm. The malpighian bodies stood out as grayish translucent points up to 1 mm. in diameter.

Microscopic Examination.—In sections from the edematous subcutaneous tissue of the chest, the collagen fibers were swollen, fibrillated and granular, and the tissue spaces were filled with granular, eosin stained, structureless material in which a fibrin meshwork was present. The tissue was richly infiltrated with polymorphonuclear leukocytes, and contained many large gram-positive bacilli, which often formed long threads. In the underlying muscle, some fibers were swollen and faintly stained, and others were compressed and hyaline; most of the fibers had lost their cross striations. Sections of organs and tissues other than the subcutaneous tissue contained a few scattered, large, gram-positive bacilli in the capillaries. In the subcutaneous tissue the bacilli were numerous.

Bacteriologic Examinations.—Cultures from the small local lesion of the neck and from the fluid of the incision, made at the time of operation, gave a pure culture of a gram-positive, nonmotile bacillus, morphologically *B. anthracis*. A blood culture made on the evening of the day before death gave a pure culture of the same organism; 0.1 c.c. of this culture inoculated subcutaneously into a white mouse caused the death of the latter in twelve hours, and from the heart's blood of the mouse *B. anthracis* was again isolated. Smears from the spleen and liver at necropsy showed the same organism obtained in culture. Cultures from the spleen gave a heavy growth of *B. anthracis.*

---

[*] From the laboratory of the Base Hospital, Camp Jackson, Marshall A. Barber, Captain, S. C., U. S. Army, Chief of Laboratory.

Diagnosis.—The findings in the case may be thus summarized: anthrax of the skin; generalized anthrax bacteremia; gelatinous subcutaneous edema of neck and chest; surgical incision of upper thorax; acute splenic tumor; passive congestion of the liver; cloudy swelling of the liver and kidneys.

Cultures were made of the shaving brush, shaving soap and razor strop used by the soldier, but *B. anthracis* was not isolated.

CASE 2.—*Clinical Course.*—A private of the One Hundred and Fifty-Sixth Depot Brigade, aged 26, white, was admitted to the base hospital, July 27, 1918, with swelling and edema of the right side of the face and neck. He arrived at camp with a group of drafted men, July 27, at 1:30 a. m., having come from Dayton, Ohio. He gave a history of having shaved at Dayton with a new shaving brush, July 24. He noticed a small, pimple-like lesion of the center of the right cheek a day or so later. When admitted there was a black necrotic area one-eighth inch in diameter at the center of the right cheek, surrounded by a red ring with a few broken vesicles. The whole cheek from the eye to the side of the neck was edematous. The supraclavicular glands were enlarged and tender. The temperature on admission was 101, going to 103 at 6 p. m. of the same day. The patient appeared only moderately ill. A diagnosis of probable anthrax was made by Major James S. Stone, chief of the surgical service.

Smears and cultures from the lesion and a blood culture were made immediately after admission. Clear serum in large amounts exuded from the inflamed tissue about the escharotic center. The smears showed the presence of a large, gram-positive, encapsulated bacillus, morphologically *B. anthracis.* From the cultures of the local lesion, *B. anthracis* was obtained. The blood culture showed no growth during the first twenty-four hours, but at the end of a second twenty-four hour period of incubation *B. anthracis* had developed. This material inoculated into a white mouse killed the animal within twenty-four hours, and from the heart's blood of the mouse, *B. anthracis* was again isolated.

Treatment and Result.—At 4 p. m. of the day of admission, 50 c.c. of antistreptococcic serum were given intravenously. The entire treatment was conservative. The lesion was not excised or incised, but was kept covered with a moist Epsom salt dressing. On the day after admission the evening temperature rose to 103.1. The swelling of the face had increased, the right eye was closed, but the general condition was good. On the second day after admission (July 29) the edema of the face had begun to decrease and the patient felt well; the maximum temperature (evening) was 101.2. By July 31 the swelling had decreased to such a degree that the right eye was open, and the temperature and pulse had returned to normal, remaining normal throughout the rest of the course of the disease. Later notes found in the clinical record are: August 4, "Condition good. Pustule cleaning." August 11, "Depression in right cheek, about size of a quarter, looks fine; granulations forming. Swelling subsiding." The further course was uneventful. The blood examination at different times gave:

	Red Blood Cells	White Blood Cells	Hemoglobin	Polymorphonuclears	Small Mononuclears	Large Mononuclears
Aug. 1	4,060,000	10,000	90%	76%	22%	2%
Aug. 2	4,060,000	10,200	....	78%	19%	3%
Aug. 16	5,300,000	4,000	95%	72%	25%	3%

Cultures were made of the shaving brush, a new one used for the first time, July 24, and not used again thereafter, but *B. anthracis* was not isolated.

Two other cases, proved by laboratory examination to be not anthrax, are of interest because they were clinically so much like anthrax that this was the probable clinical diagnosis on admission. In each case the local lesion was noticed while the patient was shaving or a day thereafter.

In the first of these two cases, in which the patient was admitted a few days after the first patient with anthrax there was a reddened area on the anterior portion of the left cheek, and the entire cheek was markedly swollen. Smears and cultures showed the presence of streptococcus. Surgical incision opened a small collection of pus deep in the cheek. Recovery was rapid and uneventful.

The second patient was admitted two weeks after the second patient with anthrax. On the right side of the chin there was a dark, dry, escharotic lesion 0.5 cm. in diameter, surrounded by a red ring, on which were a number of small, superficial vesicles from which much clear serum exuded. The surrounding skin was swollen and hard. The lesion had the appearance of a typical malignant pustule. There were no constitutional symptoms. Smears and cultures made at repeated intervals on the day of admission and on the succeeding day revealed only *Staphylococcus albus.* By the second day the lesion had lost its anthrax-like character and had taken on that of a simple abscess. The further course was that of a staphylococcus abscess, and the lesion healed rapidly without incision.

COMMENT

The cases here reported add two more to the number of cases of anthrax that have occurred in Army camps in this country. In each case the development of the initial lesion bore a relationship to the use of a new shaving brush. Although *B. anthracis* was not isolated from either brush, perhaps because the brushes had been well washed after use, it is probable that the infection in each case was derived from a contaminated brush. Because of the danger of infection by brushes made from the hairs of animals dead of anthrax, the sale of such brushes should be prohibited. Attempts have been made in this laboratory to sterilize shaving brushes on sale at the exchanges in this camp, but the various methods tried result in the destruction of a large part of the brushes, especially the cheaper kind, which are most to blame.

SUMMARY

Two cases of anthrax have recently occurred at Camp Jackson. In each case the infection was probably due to the use of a contaminated shaving brush.

One case was atypical clinically and ended fatally. In the other, which was clinically a typical case of malignant pustule, the patient recovered. In each case *B. anthracis* was obtained in blood culture.

Two other cases simulated very closely the malignant pustule form of anthrax, but were proved by bacteriologic examination to be due to pyogenic cocci.

Every suspicious lesion of the face should be examined early for *B. anthracis,* and the examination should be repeated if negative.

The sale of all shaving brushes in which there is a possibility that the hairs of animals dead of anthrax have been used should be prohibited.

Exclusion of Pylorus by Rubber Band.—A. L. Soresi passes an ordinary rubber band around the pylorus by a thread attached to one end of the cut band. The band is drawn up tight to ligate the pylorus, and the ends are tied with silk or linen thread and are then cut off close. The rubber band is the ordinary office kind, about 3 cm. in diameter and 0.5 cm. wide. The gentle persistent pressure from the band prevents the plyorus from getting a chance to open, and its power of contraction is thus gradually completely lost. The compressed portion becomes anemic, and the tissue on each side of the anemic strip hypertrophies. With any other method of occlusion, as the compressed strip atrophies, the compression grows less, and the pylorus gets a chance to contract. This cannot occur under the continuous elastic pressure which keeps up the same no matter how much the tissues beneath atrophy. His method was illustrated in the *Clinica Chirurgica,* 1917, 25, 386.

INFLUENZA

ABSTRACTS OF FOREIGN LITERATURE COMPILED BY BRITISH MEDICAL RESEARCH COMMITTEE

[Note.—The following abstract on influenza is taken from the Medical Supplement compiled by the Medical Research Committee of Great Britain and issued by the General Staff under date of October 1. It apparently covers all the important recent literature on this subject, and especially German literature, which is not now available in this country.—Ed.]

In spite of the fact that influenza recurs in modern times every twenty to thirty years in explosive waves spreading through whole continents, and that twenty-seven years have elapsed since the last pandemic, there has been neither an intelligent anticipation of the event nor certainty as to the true nature of the gigantic outbreak when it appeared a few months ago.

Responsible authors lamented the coming of a new "Spanish" disease, oblivious of history, which records epidemics of "Spanish catarrhs" as far back as the sixteenth century. Incredible as it may seem, the convenient hypothesis of "collective food poisoning" was not lost sight of. In fact, one cannot but agree with Bergmann of Marburg, who remarks that the present epidemic would not be typical if typical mistakes were not committed again this year. "The meteorologists try again to ascertain the course of the epidemic, the English again recommend quinin as a panacea, and a new erroneous teaching seeks to explain the progress and intensity of the disease (in Germany) by malnourishment, although it does not spare better stocked countries. The epidemic has always adapted itself to the rapidity of the human means of communication. In Turkestan it spreads with the rapidity of a caravan, in Europe with that of an express train, in the wide world with that of an ocean liner, and today perhaps with the speed of a Rumpel-Taube or a Fokker."

The symptomatology is held by certain authors to differ from the pandemic of 1890-1892 in certain respects, as, for example, in that acute nasal catarrh was conspicuous by its absence this year. This raises the fundamental question as to the concept of influenza. Is it the clinical picture down to the least significant symptom or the epidemiologic characters of outbreak and course of spread which make of "influenza" an entity?

EPIDEMIOLOGY

Epidemiologically the extreme contagiousness of the disease was proved to be due to its aerial convection, namely, by means of the "drop infection" from person to person, and not by transportation of the virus through the air at large, through winds, etc.

Thus in July this year in a German field regiment the first battalion to be attacked was that which fought at close quarters with a—presumably infected—American detachment. During a temporary lull companies of the other battalions fell victim to the infection in order as they were sent to relieve one another in a tunnel which was the scene of the fighting. The infection is always bound up with the diseased individual.

HISTORICAL

This infection one was taught since 1892 to regard as being identical with the hemophilic *B. influenzae* discovered by R. Pfeiffer during a secondary recrudescent wave of the last pandemic. It has often been isolated in the interval from sporadic cases or limited outbreaks of nasobronchial affections giving a picture of "grip." It was found, as a rule, in the sputum or the nasal discharge, though records of recoveries from various serous cavities, etc., are also scattered through the bacteriologic literature of all countries. Although Pfeiffer's bacillus was found to be practically nonpathogenic to animals and proved to be a very unreliable antigen, yet its regular plentiful presence in the lungs in fatal cases of bronchopneumonia during the secondary epidemics of 1892-1893, and its obvious intimate connection with characteristic pathologic processes earned for it an unassailable position as a classical specific virus. Modern bacteriology identified the bacillus with influenza, and thus the orthodox concept of this disease resolved itself into the belief that there was no influenza in the absence of Pfeiffer's bacillus. With the final disappearance of all the after-epidemics of the 1890 decade, the findings of the Pfeiffer bacillus became less frequent, yet Europe was not free from widespread localized outbreaks of influenza-like diseases. Wassermann sought to explain this phenomenon by the assumption that the population of Europe had become immunized after the prolonged prevalence of influenza, and that consequently the bacilli tended quickly to disappear from the sputum and to elude cultural recovery. However, as time went on and the bacteriologic technic increased in perfection, various organisms other than *B. influenzae* were being discovered as their several etiologic agents with as much evidence as there was for the acceptance of the Pfeiffer bacillus. In fact, if an organism was recovered from the majority of cases, if it was present in tissues in undoubted connection with the lesions, if the character of growth made of it an "unusual" host, if it was cultivated from the blood of the patients, and if it induced a serologic response on the part of patients and convalescents, there were no grounds—in modern bacteriologic reasoning—to doubt its association with the epidemic. The Pfeiffer school stuck, however, to its guns, and maintained that the various non-Pfeiffer epidemics were not a true influenza. These, in their reasoning, were all members of a large group of "endemic grip" characterized by coryza, and were similar to ancient affections well described by the authors of the seventies and eighties prior to the last pandemic. Yet, the argument continued, when the pandemic broke out, the same authors acknowledged its essential difference from the previously prevalent "contagious catarrhs," and recognized it as a disease completely new in their experience. One need not quote extracts, for, indeed, the European medical literature of the last two months abounds in statements of an identical nature! The Pfeiffer school further insisted on epidemiologic dissimilarities, and argued that Pfeiffer's bacillus was the cause of the real pandemic disease, while the multiform catarrhal outbreaks, the "endemic grip," were indeed caused by a whole museum of bacteria mainly belonging to the coccal group. This was the argument developed by Scheller, a prominent pupil of Pfeiffer, in August, 1917, when Stephan described *Diplococcus mucosus* as the agent of a clinically typical "endemic" of influenza which broke out in December, 1916, in Strümpell's clinic at Leipzig. The diplococcus was isolated from the sputum and the blood of the patients, it was specifically agglutinated by an immune serum as well as by patients' and convalescents' serum. Not unlike the meningococcus, it differed from it in that it produced a capsule in the body and mucus on some mediums that it grew on ordinary agar and at 20 C., as well as by its variable retention of Gram's staining. Nonpathogenic to animals, it could not be identified with *Streptococcus mucosus* of Schottmüller; insoluble in bile, it was not identical with the group of pneumococci, particularly the *Pneumococcus mucosus* of the American authors. Fermenting maltose, glucose, levulose and galactose, it differed from the *Micrococcus catarrhalis* group. Its immune rabbit serum differentiated it easily from both the *Diplococcus crassus* and *flavus*.

Lingelsheim promptly acknowledged the organism as one described by him some years previously during his studies on the meningococci, but Scheller, who examined Stephan's cultures, could not confirm its variable behavior to Gram, and pronounced it frankly gram-positive. It is worth mentioning that in Strümpell's clinic the influenzal infection produced by the *Diplococcus mucosus-Leipzig*, as it was designated by Stephan, was held to have been a true septicemia, and that hemorrhagic nephritis was a frequent complication, while in some cases there was distinct meningism. This last finding is of some interest, for Stephan recovered a somewhat similar organism from the cerebrospinal fluid in an epidemic investigated by him in 1916 in a fever hospital in northern France. It was found, on the whole, not to possess a marked virulence.

BRITISH EPIDEMIC OF 1915

The Leipzig epidemic was not an isolated instance of a European influenzal disturbance. Shera early in 1917 gave an account of an influenzal epidemic of the spring of 1915 in London and the southern counties, in which he claimed to have occasionally isolated a bacillus similar to *B. influenzae*, but it is somewhat difficult to identify it from the scanty details given. Lenz drew attention to very frequent occurrence of pneumonias in 1915 in German prisoners' camps. Coincidently with both the epidemics observed by Stephan, catarrhs and bronchitic infections localized in the bronchioles appear to have been very prevalent in December, 1916, and January, 1917, in military hospitals in France and also at home. The *British Medical Journal* drew attention to their extent in a special article, stating generally that their bacteriologic character was rather undecided, though a coccal (mainly pneumococcal) nature was assumed. The infections were stated to have run an acute course. At about the same period, in the late winter of 1917, a "grippal" outbreak visited Vienna and lower Austria, but *B. influenzae* was not found, because Economo (*Medical Supplement*, 1918, **1**, 220), in his account of encephalitis lethargica, insists in his differential diagnosis on this fact. Von Wiesner (*Medical Supplement*, ibid.), describing the diplococcus which, he claimed, had caused the epidemic of encephalitis, emphasized the frequent findings on postmortem examinations of that period of lesions indicative of hemorrhagic diathesis, produced, in his opinion, by the "diplococcus of encephalitis." It may be noted that this organism was held to behave variably toward gram-staining, to have been pleomorphic, and insoluble in bile. The pleomorphic diplococcus discovered and described by Rosenow and his collaborators in America at the time of the 1916 and 1917 epidemics of poliomyelitis falls undoubtedly into the same group of organisms. Incidentally it may be added that bronchopneumonias were often found to have been the determining cause of death in both the Viennese and the American outbreaks of poliencephalomyelitis.

EPIDEMICS IN 1917

The winter of 1917 was indeed pregnant with unusual diseases, for very fatal infections of purulent bronchitis were recorded at the base hospitals in France. Hammond, Rolland and Shore gave an exquisite account of their bacteriologic and pathologic characters. Gram-negative coccobacilli identified as Pfeiffer's bacillus, nonvirulent to animals, assuming coccoid forms when degenerating, were obtained from the sputums in a proportion of eighteen out of thirty; they were grown on trypsin-broth-legume-agar, and the authors, one may assume, were satisfied as to their true hemophilic nature. Pathologically, there was marked purulent bronchitis, the smallest bronchi being filled up with pus, and in some cases secondary bronchopneumonias developed. Pleurisies and empyemas were a feature, while there was also general evidence of a toxemia in the organs and the heart muscle. Signs of a right-side heart failure were frequent.

Having subsided during the summer, the epidemic seems to have broken loose again last autumn, and Hallows, Eyre and French reported very fully on an epidemic of pneumonia at the Aldershot command in September, 1917. Purulent bronchiolitis, identical with that of Hammond, Rolland and Shore, was found, and both typical *B. influenzae* (Pfeiffer) and the pneumococcus were recovered from the sputums of the organs, though *B. influenzae* was not obtained in any large proportion of cases.

INFECTIVE ENCEPHALITIS

The late winter and spring of this year witnessed the epidemic of infective encephalitis in this country, while isolated outbreaks of virulent pneumonias seem also to have been observed. At one of the London hospitals (unpublished observation) a diplococcus identical with that of Rosenow was obtained in several cases of encephalitis and frequently found in the routine examination of throat swabs. "During the first week of May of this year an acute febrile disease with symptoms resembling those of influenza invaded three factories and one industrial home for boys in Glasgow," to quote MacLean. "The bacillus of influenza was invariably absent. . . . A gram-negative diplococcus resembling the pneumococcus has frequently been obtained from the nose, throat, lungs and membranes of the brain." A few months ago Rosenow found streptococci in an outbreak of "grip" in Chicago.

Thus it is clear that in the three years 1915 to 1917 diplococci were the predominating organisms associated with influenza-like infections, although it is difficult to pronounce as to the identity of the several strains described. Hemorrhagic lesions seem to have been induced by two types. The bacillus of Pfeiffer had been found but occasionally. This was in keeping with the orthodox teaching which claimed that only a new pandemic of true influenza could finally decide, and would convince the disbelievers, as to the real specific nature of the organism. The results of the work of the last three months, however, have belied these expectations.

The two leading London medical weeklies contain to date seven original contributions to the elucidation of this crucial problem.

BRITISH LITERATURE

Little, Garofalo and Williams flatly deny that the pandemic is a true influenza. For, first, no relapses or complications were observed by them in France; secondly, in the twenty cases examined by them, there was very slight leukocytosis with a proportional lymphocytosis of a small mononuclear variety, and lastly, as in all the twenty cases, a very small gram-positive diplococcus was of "universal predominance." It was absent from the two blood cultures that were undertaken. It was recovered from nasopharyngeal and throat swabs and from the sputum. Morphologically it was flattened out on apposing sides. It appeared sometimes in pure culture. Grown on legumin-serum agar, it developed in small transparent granular streptococcal-like colonies. It showed a slight tendency to anaerobic growth, fermented no sugars and was nonpathogenic to animals.

The reported absence of *B. influenzae* would sound more convincing if the elementary precaution of planting out sputums on blood agar had been adhered to.

Burnford characterized the outbreak as an acute fever accompanied by a general polyadenitis with no specific "germs" discoverable to account for the condition.

Gotch and Whittingham examined carefully fifty cases. Leukopenia with a neutrophilia at the height of fever, accompanied by a slow pulse, were pathologic features observed. In 8 per cent. of the throat swabs and sputums, *B. influenzae* was found. In the remaining cases there was constantly present a gram-negative diplococcus not unlike *M. catarrhalis*, while in 10 per cent. of cases there was also a coccus similar to the meningococcus. The fairly large predominant diplococcus was also recovered from the blood, and its cultures proved pathogenic to man in the two instances in which the disease was experimentally transmitted by means of its cultures. The organism, if properly investigated, might be found related to the larger group of cocci previously dealt with.

On the same date Krumbhaar related in a letter the results of his study in a "small group of cases," from three quarters of the number of which a short, moderately slender, gram-negative bacillus tending to form groups and growing in typical, small watery colonies on blood agar was recovered and identified as *B. influenzae* on the ground of the foregoing characteristics. It was added that according to verbal communications from France, Pfeiffer's bacillus was being isolated from sputums.

Matthews, who examined in London "about a dozen typical cases," ascertained in every one of them by means of the West postnasal swab planted on the author's trypsinized broth-blood agar the presence of *B. influenzae* "as a rule typical, but not infrequently in enormously long filaments." On ordinary blood agar the strains recovered their typical appearance, while on the author's medium they grew in large-sized colonies, 3 mm. broad, translucent, of hemispherical shape, brownish tinged with a regularly circular outline. No more precise details are given.

Averill, Young and Griffiths had under their care 1,439 patients, of whom sixteen developed lobar pneumonias with seven fatal issues. No account is given of postmortem examinations. Forty-three cases were examined bacteriologically. *B. influenzae* was not detected in the nasopharynx, a gram-positive diplococcus being predominant. The sputum of forty-one patients showed in thirty-two cases the presence of the same diplococcus associated with a gram-negative bacillus often in clumps. In nine other instances the diplococcus retained the field to itself. Grown on ordinary agar the sputums yielded colonies of the diplococcus only, while on blood agar discrete, transparent, smooth, rounded-edged colonies developed in addition. On prolonged counterstaining of the culture smears with 5 per cent. carbolfüchsin (ten minutes), small gram-negative coccobacilli with rounded ends, slightly bipolar and slightly larger than in the direct films were detected. They refused to grow on ordinary agar, fermented no sugars, and were, therefore, identified as Pfeiffer's bacillus, while the coccus was diagnosed as a pneumococcus.

Both these conclusions require further evidence, as the description of the coccobacilli fits in rather with the characters of Bordet's *B. pertussis* than of the classical bacillus of Pfeiffer, while no reasons are given for the assumption of a pneumococcal nature of the diplococcus.

Finally, Maude, who observed 2,067 cases, of which 248 were hospital admissions with three deaths, insists on the high percentage of patients who developed the complex lung conditions previously described by Hallows, Eyre and French. No systematic bacteriologic examinations were made by the author, who relies on the definition given in September, 1917, by Eyre of a double successive infection by *B. influenzae* and the pneumococcus.

Thus—on a summary—*B. influenzae* was doubtfully reported in some, undoubtedly present in other groups of cases, while two types of cocci were predominant in the hands of the remaining authors. Unfortunately the material actually dealt with so far was not sufficient in quantity to warrant the responsibility of drawing therefrom any general conclusions.

GERMAN LITERATURE

In Germany the widespread outbreak of influenza aroused a considerable and immediate scientific interest; the medical societies of Berlin and Munich held special meetings early in July, at which the identity of the prevalent disease with the last pandemic was recognized by a majority of the authorities after detailed discussions. This recognition was made all the easier as organs preserved since 1890-1892 were found on comparison with those obtained from fresh fatal cases to exhibit corresponding lesions, Lubarsch and Hansemann particularly insisting on the essential similarity.

The morbid anatomy of the present pandemic was studied in detail by a number of authors. Thus:

Oberndorfer investigated a large series of postmortem examinations in Munich (number not stated: apparently thirty-one).

Lubarsch reports on fourteen postmortem examinations from Berlin.

Schmorl reports on fifty postmortem examinations from Dresden.

Bernhardt and Meyer report on twenty-eight postmortem examinations from Stettin.

Simmonds reports on twenty-eight postmortem examinations from Hamburg.

Hirschbruch reports on sixteen postmortem examinations from Metz.

Dietrich reports on seven postmortem examinations from a field laboratory.

Bergmann (Marburg), Selter (Königsberg) and Gruber and Schädel (Mainz), a few each.

Oberndorfer's, Schmorl's and Lubarsch's descriptions may be taken as a standard, the other authors generally finding themselves in agreement with them.

Oberndorfer examined only very acute cases of the first fortnight of the epidemic. These were all men, mainly between the ages of 17 and 25. The lesions of the respiratory organs were so typical that the author could almost dictate seriatim identical protocols.

SYMPTOMS AND PATHOLOGY

In the initial stage of the affection of the lungs, namely, when only small foci without any great reaction in the immediate neighborhood are observed, the most striking findings were small, bean-sized hemorrhages projecting into the lung tissue. As a next step there followed a firmer infiltration of the parenchyma, the nodules sitting subpleurally and raising the pleura in consequence. A whole scale of intermediate formations lay between these small nodules and large hemorrhagic tuberous infiltrations; all possible gradations were observed from simple blood extravasations into the lung tissue, still containing air, to firm, almost dry, infarct-like hemorrhages of a bluish-black tinge. These extensive infiltrations were of the same shape as the usual pulmonary hemorrhagic infarcts, namely, they had the form of a wedge with its base resting on the pleura, thus clearly indicating an intimate relationship with the vascular system of the lungs. In this purely hemorrhagic initial stage no thrombi were ever found in these arteries, the extravasation of red cells being obviously due to an abnormal permeability of certain portions of the arterial system.

The second stage was characterized by exudative pneumonic processes combined with hemorrhages. The picture varied considerably at times. There may be a true croupous hepatization of lobular, or even lobar, extent, both red and gray, though the tinge was usually brownish and not as a rule very distinct. These pneumonic infiltrations usually embraced in their center circumscribed hemorrhages. The surface on section was not dry, being covered by a slimy, dirty coating, thus resembling a picture of Friedlaender's pneumonia. The pneumonic foci were sometimes flattened out at the ends into yellowish white wedge-shaped strictures corresponding to anemic infarcts both in form and color. These often became the seat of gangrene or suppuration, the pleura also being obviously involved in the process. In the majority of cases it was a catarrhal and desquamative succulent infiltration rather than a fibrinous exudation, but almost always severely complicated by suppuration.

The bronchi were filled with pus already in the first stage, the smaller branches containing thin fluid, though at times dried-up exudates formed firm plugs occluding the lumen of the bronchioli. This purulent bronchitis had as its consequence an extensive bronchiectasis with the bronchi distended cylindrically. The bronchi and their blood vessels were often surrounded by purulent infiltrations originating from the lymphatic system. In other cases, again, there were seen on section enormous numbers of minute abscesses surrounded by hemorrhages, the suppuration being obviously hematogenic in origin. These minute abscesses often became confluent, thus ending up by the formation of large caverns of pus.

The pleura participated in the process. The first signs consisted in punctiform hemorrhages, or ecchymoses; serous exudations followed next, and, as often as not, empyemas completed the picture. As a rule, one side only was affected. Pericarditis was a natural consequence of pleuritis. There were no gross changes in the heart save for some thickening of the arteries of the lung hilum. Occasionally incipient endocarditis was encountered.

The larynx and the upper third of the trachea showed no involvement in the process. The lower portion, however, was the seat of an intense mucopurulent exudation, which in many cases assumed a fibrinous character, with the consequent formation of extensive pseudomembranes in the lower trachea and down into the bronchi. Sometimes edema of the epiglottis was observed.

A striking feature was presented by the hyperplastic condition of the lymphatic apparatus of the tongue and the tracheal ring. The thymus was well preserved, the cervical and axillary, but not the inguinal, glands were enlarged. On the whole, an impression of the existence of a status thymolymphaticus was conveyed. As young individuals were mainly affected, these two facts may stand in a relation of cause and effect.

The spleen was enlarged, sometimes a septic spleen tumor being found.

The liver was but seldom involved; the kidneys showed a general hyperemic condition. In the brain and the meninges there was a marked vasodilatation, but no meningitis was noted. Punctiform hemorrhages, in the form of a purpura hemorrhagica, were met with in the corpus ammonis and the cerebellum.

The histologic examination revealed the following unusual findings: in the trachea, an intense exudation of fibrin in the deep layers of the mucosa, and a progressive inflammation of the deeper portions of the tracheal walls; in the lymphatic glands, an enormous vasodilatation, hemorrhages, as well as proliferation of the endothelium, particularly in the axillary glands.

The foci of inflammation in the lungs showed a leukocytic infiltration around the alveoli, bronchi, and the walls of small arteries. It did not involve the whole vessels, which were dotted with isolated spots of infiltration. There were also hemorrhages into the heart valves, with a consequent displacement of the fibers and damage to the endothelium; thus no definite endocarditis, but lesions, which facilitated the development of a secondary mycotic endocarditis. There were, therefore, signs of a lesion of the walls of the vessels, which were particularly marked in two cases in the arteria pulmonalis. A very advanced mycotic arteritis was detected here, exhibiting a leukocytic infiltration of the whole wall, particularly of the innermost layers, with displacement of elastic fibers and a necrotic fibrinous coating on the partly necrosed intima. The gram-staining revealed the presence of masses of streptococci, though there was no indication in these cases of a lymphangitis. Thus the whole character of the lesion, and particularly the localization of the most intense process on the internal wall, points to a primary affection of the intima.

PATHOLOGIC PICTURE

The essence of the whole pathologic picture consists, therefore, in the abundance of hemorrhages seen in the mucous and serous membranes, in the respiratory tract, and in the lungs, which indicated a damaged condition of the capillary vascular system. The abscesses, save for those originating in the bronchi, were also of a hematogenic nature. The whole process seems to be primarily a bacteremia localized in particular in the pulmonary blood vessels. Hemorrhages in the lungs pave the way for a secondary infection, the results of which dominate the whole field in the later stages. In any case the wedgelike shape of the pulmonary foci indicated a vascular origin of the lesions. From a purely anatomic point of view the condition bears many points of resemblance with pneumonic plague, though there is no indication as to an entry of the virus through definite lymphatic channels. The primary bacteremic condition was not found to be due to *B. influenzae* (Pfeiffer), and thus the invading virus remained undiscovered.

Lubarsch found essentially similar lesions in his fourteen cases. The age and sex incidence was the same, all being men, six of them under 20, five between 27 and 29, and only three over 30 (30, 33, 42). They were particularly well-built and well-nourished individuals. The author lays more stress than Oberndorfer on the pseudomembranous condition of the lower trachea and the bronchi, which sometimes attained the intensity of a true diphtheritic inflammation in the sense of Virchow, one could almost say of a necrosing inflammation. The changes in the lungs are particularly characterized by the tendency to spread over the pleura in an extraordinarily quick time, so much so that a genuine necrosis of the pleura is sometimes seen. In some cases the pleuritic lesions constitute the main damage, and death is caused by the consequent compression of the lungs. The essentially hemorrhagic character of the pulmonary processes is shown by the fact that in the rare cases in which the naked eye appearance gives no ground to suspect hemorrhages these are revealed by microscopic examination. Blood extravasations were also found in the mucous membranes of the stomach, the intestines and in the pelvis of the kidneys.

B. influenzae was found only once, namely, by microscopic examination of a section of the lungs. Streptococci were usually recovered from the blood, the lungs or the spleen. It is these organisms which caused death, not through generalized infection, but by producing fatal local lesions. Pfeiffer's bacillus, should it ultimately be found to be the primary cause of the pandemic, is not in any case a virulent agent, its exclusive multiplication in the body leading only very occasionally to a fatal issue.

Schmorl's fifty patients again corresponded in age incidence with the previous series. The ages of forty-seven ranged between 11 and 27, the remaining five consisting of two aged 48, two 36, and one 70. They were all persons in vigorous health. While in general agreement with the previous authors, he was particularly impressed by the diphtheritic inflammation of the trachea and bronchi, which he examined very carefully in sections, and found streptococci and pneumococci, occasionally staphylococci, associated with it, but neither *B. influenzae* nor *B. diphtheriae*. This condition is, in his opinion, very rare in influenza, but forms a strikingly common feature of the present epidemic; if diligently looked for, it will not be missed in many cases. A waxy degeneration of muscles, particularly the rectus abdominis, was encountered, as an indication of a central toxic influence.

But the most interesting finding of Schmorl is the frequent occurrence of hemorrhagic encephalitis. During the 1890 pandemic Schmorl made 120 postmortem examinations at Leipzig without recording this condition once. This year out of forty-four cases in which the central nervous system was examined, it was present in fifteen. The white substance of the cortex and both the gray and white of the central ganglions abounded in punctiform hemorrhages, the posterior part of the corpus callosum being most affected. The cerebellum, pons and medulla oblongata, as well as the parenchyma, are only occasionally involved. In some cases the thalamus opticus alone shows the lesions. Histologically, the few sections made so far show circular hemorrhages with a necrotic center situated around small vessels, while the periphery of the necrosis is surrounded by agglomerations of large cells, which also embrace the extravasated blood corpuscles. In other cases there is but a simple destruction of the substance of the brain by the extruded red cells. There were no pronounced inflammatory lesions. Of the seven brains examined bacteriologically, in two very small diplococci were found, which grew on blood agar like *B. influenzae*. The author questions, however, their etiologic significance. In spite of some disparity in pathologic findings, the author considers the infection to be real influenza, but he rejects Pfeiffer's bacillus as its cause, since it was found in the bronchial mucus in only three out of his fifty cases.

The other authors add few important observations. Simmonds maintains that the only difference as against the 1890 pandemic consists in the more frequent occurrence of secondary streptococcic infection. Bacteriologically he found *B. influenzae* in both the sputum and the postmortem material, "very frequently." Hirschbruch found *B. influenzae* in one case, the remaining fifteen being associated with cocci. Gruber and Schädel insist on the frequency of periarteritis and panarteritis, and note an acute dilatation of the right heart in most cases, a finding identical with that of Hammond, Rolland and Shore (see above). Diplostreptococci were the only bacteria found by them. Bergmann never found Pfeiffer's bacillus in postmortem material.

The observations made by Dietrich in the field deserve special mention. *B. influenzae* was recovered from the first seven postmortem examinations and identified as such by Neisser. They were found during the acme of the process in the alveoli, between the leukocytes or under the epithelium, or again in small mucous plugs occluding the bronchioli; there were none or very few in a multitude of other species in the trachea. The more advanced the lesions the more complex their bacterial form. In his opinion, Pfeiffer's bacillus was the "pioneer" of the lesions, while the secondary infections proved fatal. He denies the occurrence of a *status thymo-*

lymphaticus and believes that the exertions of the service, wounds, etc., prepared a disposition in his cases. Hemorrhagic diathesis of the tissues and very frequent findings of streptococcic meningitis and endocarditis differentiate his results from that of the other authors. He also agrees with the assumption of a primary affection of the vessels, but it is *B. influenzae* which in his opinion inflicts the damage, being also responsible for the edematous purulent bronchitis and thus forming a favorable basis for the subsequently fatal secondary infections.

Bernhardt and Meyer divide their twenty-eight cases into three categories: (*a*) Six severe hospital cases in which there were other affections and which were secondarily infected with influenza; (*b*) seven mild hospital or outside cases weakened by the previous illness; and (*c*) fifteen healthy individuals or surgical patients who were admitted to hospital for influenza. In this way the authors claim to have been able to watch the progressive development of the pathologic process, which in no way differs from that described by Oberndorfer. The inflammation of the intima in pulmonary arteries was noticed in one case. Encephalitis was present once, but it was a purulent hemorrhagic inflammation. Perichondritis arytenoidea and hemorrhages into, and swelling of, the suprarenals were among occasional findings. On the whole the process was localized almost entirely in the lungs and in the pleura in conformity with the experience of the 1890-1892 pandemic. *B. influenzae* was found in no instance, the majority of the cases yielding a pure growth of diplostreptococci which were obtained from the lungs, the heart blood, spleen and liver. It is difficult to decide whether all the strains belong to the same species. They tend to degenerate in involution forms; the virulence for mice varies from strain to strain and from culture to culture, to the extent of 0.001 c.c. to 0.1 c.c. of a broth culture by intraperitoneal injection. There may be, however, a relative unity of species in view of the contagiousness of all the strains and the explosive character of their transmissibility in a given group of patients (a hospital ward, barracks, etc.). The organisms must be regarded as companions of the unknown primary agent of the pandemic, the epidemiologic and pathologic symbiosis being regulated by definite biologic laws. In any case the cocci are of decisive importance for the pathogenesis of bronchopneumonias and all fatal complications.

Bernhardt previously examined forty-seven acute cases during life, and while failing to isolate *B. influenzae* from any, he regularly recovered from the cultures of the posterior throat and the expectorated mucus the same diplostreptococcus in enormous numbers and often in an almost pure condition. In direct films they are frequently intracellular, mainly in twos, sometimes in thick groups or in whole chains of four to six members. Minute in size, they appear oval or round, an impression of a capsule being at times conveyed. Growing sparsely on ordinary agar, they give on ascitic agar very small, translucent, round, sharp-edged, flat colonies which do not become confluent, however abundant the film. On human blood agar the very minute colonies seem to avoid the portions with deep layers of blood. They are hemolytic if not more than one twentieth to one thirtieth of blood is added, changing the color to a black greenish tinge like *Streptococcus mitior*. The cultures are not soluble in bile. Distinctly gram-positive, the organisms tend to involute, longish chains being met with composed of single cocci varying in size within one chain or in different chains in one field, so much so that an impression—proved experimentally to be erroneous—of a mixed growth is obtained. From glucose broth two varieties of colonies develop: a typical, delicate, clear and a thicker slimy colony which consists of twelve to fifteen membered chains. The cultures are not very viable, twenty-four to forty-eight hours sufficing to reduce greatly the abundance of subgrowth. Ascitic broth cultures are virulent to mice. In normal controls the organism is not encountered or is extremely sparse if present. Patients while coughing conveyed the organism to a distance of at least 50 cm., the colonies growing on exposed plates in groups of ten to fifteen. Such experiments were negative with convalescents after the fall of temperature. The diplostreptococcus is very aptly designated by Bernhardt as *Diplococcus epidemicus*. It bears most resemblance to *Streptococcus conglomeratus*.

Mandelbaum, who investigated bacteriologically Oberndorfer's cases, recovered streptococci in twenty-five, pneumococci in three, staphylococci in two, and *Streptococcus mucosus* in one case from the bronchial secretion on postmortem examination. He does not specify the characters of his cultures, which he considers all as secondary infective agents equally responsible for the lesions. He denies emphatically the causal relationship of Pfeiffer's bacillus to influenza. It should have been present in the lungs if it were the agent of the pandemic. The remarkable immunity of the groups of population over 30 clearly indicates a survival immunity to influenza, whereas classical experiments of Delius and Kolle had shown that Pfeiffer's bacillus is incapable of inducing active immunity in the animal body. It has been often isolated since 1892 in various countries, and yet there was no pandemic, in spite of its ubiquity. Thus other factors must be responsible for the outbreak of influenza.

Selter also failed to find *B. influenzae* in the sputums of thirty-three cases examined at Königsburg, although the cultural investigations were carried out with all care and rapidity. He does not consider Bernhardt's *Diplococcus epidemicus* to be the agent of pandemic. It belongs to the group of pneumococci, and is no doubt transmissible with the real virus. This—he agrees with Kruse—belongs most likely to the family of aphanozoa, invisible microbes, for it is striking that Pfeiffer's bacillus met until 1904 in many outbreaks was entirely absent from the big epidemic of 1908 in western Germany and France. He submitted himself and his woman assistant to an interesting experiment: their throats were sprayed for one-half minute with a saline filtrate of throat swab and throat washings of several patients. Both of them developed a typical though mild attack of influenza.

Kroner, Kisskalt in Kiel, Friedemann in Berlin, Kolle in Frankfort and Hirschbruch at Metz have failed to isolate *B. influenzae*. Kolle, it may be remembered, found a diplococcus apparently identical with that of Bernhardt.

Gruber and Schädel occupy an intermediate position. Of the 250 cases examined at Mainz they found *B. influenzae* only in fourteen, while from the overwhelming majority diplostreptococci were recovered. Bergmann found both the pneumococcus and *B. influenzae* at Marburg, the latter being isolated in a high percentage, in fifteen out of the twenty sputums examined. The strains were identified on the basis of the few typical characteristics. Pfeiffer (*Medical Supplement*, 1918, **1**, 306) has so far confined his observations to a short note stating that the inconstant finding of his bacillus was still under investigation. Simmonds reported very frequent findings of Pfeiffer's bacillus at St. George's Hospital at Hamburg, while Dietrich isolated regularly *B. influenzae* in the field, and had his cultures identified by Neisser. Gotschlich obtained 12 per cent. positive cultures from a series of twenty-three sputums in Giessen.

Uhlenhuth, a "die-hard" of bacteriologic orthodoxy, has clearly shown signs of uneasiness. Two series of cases were carefully scrutinized. In one group of fifty-one, "suspicious" bacteria were seen in direct films in 66 per cent. of specimens of sputum, the cultural recovery being limited to 13 per cent., while in addition one empyema and one throat swab yielded the looked-for growth. In a second group of forty-seven, eighty-four sputums were examined, and thirty-three cultures obtained from twenty-two cases, a percentage of recovery equaling 46.8. Blood cultures were uniformly negative. Thus Uhlenhuth cautiously concluded that *B. influenzae* is detectable in "not inconsiderable numbers." Yet he admits the extraordinary scantiness of the bacilli in films, although he blames the young bacteriologists for either not knowing how to recognize Pfeiffer's bacillus or inversely for producing, when challenged, cultures of any small gram-negative bacillus as *B. influenzae*.

He believes that experimental transmission of the disease should be tried; he himself failed to infect a monkey with Pfeiffer cultures, and shrank from experimenting on man in view of the danger of a complicating pneumonia. No "urgent reasons" exist in his opinion for abandoning the conception of the etiologic importance of *B. influenzae,* and he warmly recommends the use of the new mediums advocated by Levinthal.

Levinthal, some months before the epidemic started, set out to strengthen Pfeiffer's concept of influenza by raising the percentage of positive recoveries from sputums. It is admitted on all hands, and it has also found expression in the reports of the skeptics, that *B. influenzae* is notoriously difficult to cultivate even from a material microscopically swarming with it.

Symbiotic cultivation, particularly in a mixture with staphylococci, was experimented with many years ago, and furnished valuable indications as to the biology of the microbe, but did not prove a helpful means for routine diagnosis. It is, of course, a commonplace of bacteriology that *B. influenzae* thrives on hemoglobin and its break-down products and not necessarily on fresh blood. Guided by this, Levinthal concocted a new medium by adding fresh blood in a proportion of 1:20 to melted sterilized faintly alkaline agar, and, after thoroughly mixing, by boiling the whole for a few minutes, and then bringing it twice more to the point of ebullition. The blood clots and reclarifies the medium, which should now be filtered aseptically through gauze or paper, and kept ready for use in deep test tubes. The resulting agar is perfectly transparent, and grows *B. influenzae* in giant absolutely translucent colonies.

The yield is increased very considerably, the filamentous pseudoforms of the bacilli revert to the type, and, more important still, the cultures emulsify readily and keep in suspension without clumping spontaneously. Thus a basis was obtained for the application of the agglutination test as an additional means of diagnosis. Levinthal claims that live cultures on his medium produce highly specific potent serums when injected into rabbits, and that inversely patients or convalescents, but not controls, agglutinate his emulsions electively in dilutions of one fiftieth to one four-hundredth.

While highly praising the enriching qualities of this medium, Uhlenhuth was unable to confirm the virtues of the suggested "influenza Widal," which seems to have passed unheeded in the German literature.

. . . .

The story breaks here at present, and although Pfeiffer may yet furnish reasons why the verdict should not be pronounced, there is already sufficient material to shake the orthodox conception out of its high altar. Two facts stand out prominently: the generally acknowledged, or by some reluctantly admitted, absence of *B. influenzae* from the organs on postmortem examinations, and the universally recorded findings of diplostreptococci, singly or in association with the Pfeiffer bacillus.

DISCUSSION

The Pfeiffer conception, robbed of all hypothetic superstructure, rested in its essence on the fact of the obvious intimate relationship between bronchopneumonic lesions and the—practically never absent—bacilli. In 1892-1893 it was already reported that sputums may yield negative results; but the postmortem findings silenced the critics, who were persuaded that it was only faulty technic and capricious eccentricity of an unusual organism which vitiated the otherwise perfect harmony of theory and histologic pictures. Some few fossils of the heroic epoch never admitted defeat, and one of them, Hueppe, in an open letter to the *Deutsche medizinische Wochenschrift,* triumphantly points to the present negative findings as confirming his unabated disbelief in the etiologic significance of the hemophilic bacillus.

Doubtless the present outbreak deviates in certain particulars from the last pandemic. First, the age incidence is remarkable, and it must frankly be conceded that the hypothesis of a "survival immunity" is not convincing, since similar factors should have operated twenty-seven years ago, when they did not. One should rather agree with Lubarsch that the disturbance of the war has caused a profound alteration in the normal course of the epidemics. Indeed, there is the precedent of poliencephalomyelitis, which many authors sought to differentiate from the Heine Medin concept on the basis of an unusual age incidence. Secondly, the blood picture is not one of leukocytosis, as classically described. Levy, at the Berlin Charité, came to conclusions corresponding with the English experience, namely, that there is leukopenia at the expense of polynuclears, the lymphocytes and large mononuclears increasing proportionately, the latter reacting sometimes even 21 per cent. of the total. Leukocytosis should be regarded as a sign of complications, while complicating infections without it are prognostically ominous. Thirdly, there is the seasonal difference (spring and not autumn), and the apparent western origin of the explosive outbreak. As to that, great caution is indicated. The whole globe being at present a "ward in censorship," it is not possible to decide whether the present is a European or a world pandemic, a problem of great importance in view of the seemingly varying cycles of the two (twenty to thirty to forty to fifty years), a circumstance which might throw light on factors regulating the immunity. Neither is the western origin to be taken as granted. Ginns, at the Medical Society of Berlin, suggested that the virus might have been imported by Chinese laborers, employed behind the front, while Legroux of the Pasteur Institute stated in the public press that the "Spanish" disease made its first appearance in the area of Dunkirk, and only thence traveled southwest. The absence of prodromal catarrhal symptoms may be explicable by the unusual season of outbreak, and it is to be feared that epidemiologic purists may yet obtain satisfaction at seeing a much graver catarrhal form during the second tide, which already had begun to rise in Spain and in Sweden, as well as in Italy, as an apparently more severe illness.

Without laying too great a stress on the (so far) scanty publications from the field, it cannot be denied that *B. influenzae* was more often recovered from troops in the battle zones, who seem to have been subjected to a much milder type of attack. It is interesting to note that the Budapest clinic claimed to have isolated the Pfeiffer bacillus from every case examined—a fact which, if correct, might be correlated with the observations from the fronts.

The cold logic of the postmortem room in the dispassionate home surroundings does not leave, however, any doubt that Pfeiffer's bacillus when present did not play any more important part than the ubiquitous diplostreptococci. The real virus classified "faute de mieux" as "invisible" or a "filter passer," so as to cloak our ignorance of its nature, remains to be discovered.

THE DIPLOSTREPTOCOCCI

The diplostreptococci, although secondary in point of time and apparently primary in deciding a fatal issue, seem to be transmissible from man to man equally with the main virus. The observation that bronchopneumonias tend to spread in the wards of fever hospitals was made years ago, and there are institutions, as, for example, the Plaistow fever hospital, which include the disease in their list of infections to be "barriered." The remarkable frequency of fatal pneumonias during the last three years has been commented on. It seems to have risen again some two months before the first tide of this pandemic almost all over Europe. It was characterized by the circumscribed character of the outbreaks and by a preference for attacking young, vigorous men. There is room for inquiry whether these isolated epidemics were not the brewing ground, the preparatory drum fire, preceding the general assault by the main virus. It may cause surprise that these bacteria were not universally encountered before, or that, if met with, no significance was attached to their presence. But, first, there has been growing of late a tendency for disregarding organisms of the textbook type as mere obsolete formations, a sort of background scenery amid which the real virus must hide somewhere in its commonly assumed invisible form. Secondly, with a few exceptions, these diplococci remain unclassified both on account of the unsatisfactory or insufficient standards of identification, and of the deplorable multiplication of researchers who have invaded laboratories with a very inadequate scientific equipment aggravated by a firm refusal to practice modesty of conclusions, or to observe elementary accuracy in recording observations.

A breadth of outlook is also a necessity. The cyclical appearance of epidemics causes no surprise, but it is obviously based on a (so far) unaccountable periodic visitation of the globe by unusual bacteria. It may be that the diplococci are the novelty of the present season, condemned to oblivion after the ebb and flow of influenza and its companions will subside, and Bernhardt's designation of *Diplococcus epidemicus* is a fitting provisional label. Among the companions of "grip," epidemiology records almost regularly coincident epizootics among horses. There are two varieties: the "pink-eye," the *Pferdestaube*, or *Druse*, strangles of English and *gourme* of French authors, a coryza contagiosa equorum clinically manifesting itself as an influenza catarrhalis, and the pneumopleurisy, *Brustseuche*, an influenza pectoralis. Now, the latter infection gives anatomic pictures closely resembling those of the present pandemic. Purulent fibrinous bronchitis, bronchopneumonias, swelling and suppuration of lymphatic glands, as well as the lightning character of the outbreak and the prevalence of the first catarrhal variety on the onset, make of this epizootic an analogous infection. Some authorities hold that the two epizootic types are distinct "entities," and the *Streptococcus equi* of Schütz has been long ago identified with strangles, while the French school of Lignières associates *B. bipolaris-equisepticus*, a member of the manifold group of "Pasteurella," with the pneumopleurisies. The strangles has been lately transmitted from horse to horse by means of filtrates of infectious material, while Gaffky and Lührs have infected horses with inflammatory mucus of the pneumopleurisy at a stage of its microscopic sterility. There is complete unanimity, however, that the two bacteria are commonly found in the excretions and organs of the exudative inflammatory period of suppuration. Now *Streptococcus equi* in microscopic morphology and type of growth strikingly resembles the diplococcus of Rosenow, and most likely the *Diplococcus epidemicus* of Bernhardt. As to *Bacillus bipolaris-equisepticus*, morphologically it is indistinguishable from some of the gram-negative bacilli described by certain authors mentioned above as Pfeiffer's bacillus deviating from the type. It is not, however, hemophilic, and grows easily on ordinary mediums. It is undeniable, nevertheless, that during the present pandemic bipolar gram-negative, delicately growing, and nonhemophilic bacilli were often isolated from the organs. Hirschbruch, who regards these organisms as most likely corresponding with the bacteria of the human infections, draws attention to the fact that neo-arsphenamin, a proved remedy for the epizootics, has been successfully applied in Switzerland in the treatment of severe cases during the present pandemic. The Swiss have also isolated Pfeiffer's bacillus only occasionally, and also dwell on the presence of secondary diplostreptococcic infections.

Thus a fruitful field for research is opened in many directions. It is, unfortunately, only too certain that a second and more severe wave of influenza will spread over Europe in a few months. The results of the experience gained so far suggest that active immunization, both for prevention and treatment of the grave complications, with the diplostreptococci should be attempted. Streptococcal serotherapy might also be tried. A large group of several hundreds of cases should be thoroughly investigated by a team of workers—clinicians, bacteriologists, morbid anatomists and epidemiologists—working in correlated agreement. Experimental transmission to animals should enter in the scheme, while cultures obtained from various districts should be sent for classification and comparison to the main working center.

The team of workers would doubtlessly remember that "it is the property of things seen for the first time, or for the first time after long, like the flowers in spring, to reawaken in us the sharp edge of sense and that impression of mystic strangeness which otherwise passes out of life with the coming of years."

Rest and the Tuberculosis Patient.—The influence of rest in abating the severity of an inflammatory process is well known. The effect of motion and of friction in spreading infection from a suppurating focus is a familiar surgical fact. Not only should deep breathing be avoided in the tuberculous patient but motion of the upper extremities should be reduced to a minimum. Rest is also highly desirable to promote a cicatrization and encapsulation. And lastly rest of the body is needed for its recuperation. Psychic and physical relaxation should both be practiced. The neurasthenic tuberculous patient with the anesthesia of fatigue or the restlessness of the overfatigued who are "too tired to rest" must learn to rest and relax not only to recreate his energy in some measure, but to store it up. Rest must be the only means associated with the outdoor life so far as is practicable.—*Amer. Rev. of Tuber.*

OBSERVATIONS ON THE PRESENT EPIDEMIC OF SO-CALLED INFLUENZA IN EUROPE

The highly interesting abstract of recent English and German articles on so-called epidemic influenza, prepared by the British Medical Research Committee and printed verbatim in this issue of The Journal,[1] invites a few brief comments. The abstracts do not convey any clear information as to the extent of the spread or the severity of the disease in Europe. Judging, however, from the number and the nature of the articles abstracted, it looks as if the disease, thus far at least, has been more severe and more extensive in Germany than in England. One also receives the impression that the results of the bacteriologic and anatomic studies in Germany correspond more closely, perhaps, to the results that are being obtained in this country than do those coming from England. But it is entirely too early, of course, to form any reliable conclusions.

The articles abstracted seem to have been meager in clinical detail. It is evident that the observations at hand do not indicate the present epidemic to be a distinct clinical entity, clearly differentiated in its clinical activities from similar previous epidemics of more limited extent. The present epidemic apparently differs from these earlier epidemics mainly in contagiousness and in its extensive spread. The many minor epidemics of respiratory infections preceding the present epidemic are of great epidemiologic interest, but their true relation to the European influenzal disturbance can probably not be traced accurately. The fundamental anatomic changes in influenza, according to the German reports, seem to have been hemorrhages, especially in the respiratory tract, as well as inflammatory foci, the whole suggesting to some of the investigators a primary infection of the blood with localization especially in the pulmonary vessels. It would seem, however, that the possibility of direct infection of the respiratory tract cannot be excluded. These changes are regarded as paving the way for secondary infections. It is of great interest that there is no unanimity of opinion whatever as to the nature of the primary infecting agent.

The bacteriologic results do not appear to warrant the assignment of any greater importance to the influenza bacillus than to the organisms described as diplostreptococci. These diplostreptococci are not described fully, but they most probably are nonhemolytic streptococci of the viridans type. Only slight mention is made of hemolytic streptococci or of pneumococci, which appear to be isolated in a certain proportion of the cases of influenzal pneumonia in this country.[2]

On the whole, the results of the work covered by the abstracts support the conclusion that we do not understand the true nature of the condition now being called epidemic influenza; that there is not sufficient evidence to regard any one of the different forms of bacteria found in the respiratory tract in the cases of the disease as the primary cause, but that all the bacteria, the influenza bacillus, as well as the so-called diplostreptococci and others, may be secondary invaders, transmissible from person to person with almost the same ease as the supposed, but unknown, primary cause. The one experiment mentioned bearing directly on the question of the exact etiology of epidemic influenza is that by Selter, who produced a typical but mild attack in two persons by spraying the throat with a filtrate of influenzal throat secretions; but not enough details are given so that one can form any judgment as to the value of this experiment.

THE REDUCTION OF BODY WEIGHT IN WAR TIME

Reports that have reached this country from Germany at intervals since the beginning of the world war have indicated that the unquestioned shortage of food has not been without effect on the civil population. It has been freely stated that a loss of body weight has in many cases followed the reduction in the available food. In some quarters the lowered intake necessitated by the emergency, particularly a year or more ago, has been hailed as a change by no means disadvantageous to the organism. "We eat too much," according to the dictum of those enthusiasts who see only advantage in an enforced dietary economy for a large part of the civil population, particularly for the great number of sedentary persons whose energy demands are primarily determined by the routine necessities of life rather than by muscular work of an arduous sort.

Since the American people have also been called on to exercise economy and avoid dietetic extravagances, it is timely to ask what the available evidence justifies us in concluding on the subject of reduced rations. There seems to be little doubt that the rumors of reduction in body weight are not without foundation. Loewy,[1] a Berlin physiologist of experience in the study of nutrition, reported some time ago, as the result of statistical inquiries made by him, that already in April, 1916, the restriction in the food intake among large groups of the population was represented by an energy intake of between 2,200 and 2,300 calories a day, with an average protein content of from 65 to 68 gm. Loewy believed that such a regimen may be adequate in respect to its quota of protein, but that the energy that it represents would in general scarcely satisfy a sedentary person.

Since then a significant confirmation of the effect of the war time diet on the weight of the average German male citizen has been disclosed through the authority of Prof. Friedrich Müller, the Munich clinician. He has reported that in Munich men under 50 years of age had experienced an average loss of weight amounting to 10 per cent. in the two years preceding 1918. This leads his assistant, Dr. Jansen,[2] to remark that the former norm of 70 kg. for the adult man must be regarded as represented by 60 kg. in 1917 in Germany. Among a group of medical students examined by Jansen in the spring of 1917, all had experienced losses of weight amounting to 4 or 5 kg. during the war.

Such experiences raise the question as to the actual effect of a prolonged and considerable reduction of the diet on the metabolism. Since the law of the conservation of energy applies in the human organism, the food requirement must be equivalent to the metabolism in any event. Is this a fixed factor, so far as the maintenance component is concerned, or does it become altered with changing planes of nutrition? When the body weight declines as a result of short rations, is a point of equilibrium finally reached at which the scant supply suffices? To answer such pertinent questions Jansen has made observations on men averaging 62 kg. in weight and kept on restricted diets including 60 gm. of protein and 1,600 calories a day. The basal metabolism of these persons (at rest without food) averaged 1,400 calories. On the limited food intake there was continued loss of protein, amounting to nearly 12 gm. a day. When an additional 500 calories in the form of carbohydrate (lactose) were fed, the loss of nitrogen was nearly averted, showing that when enough total food energy is furnished, 60 gm. of protein in the daily diet may suffice to prevent loss of nitrogen from the tissues.

So far as the observations on the minimal protein requirement are concerned, there is nothing essentially new in these findings. It has repeatedly been demonstrated that the conventionally assumed requirement of more than 100 gm. of protein a day is unnecessarily high in the light of modern researches. The energy features of the restricted diets cannot be so lightly dismissed. After reduction in body weight there was a lowered basal metabolism, which Jansen, like Loewy and Zuntz,[3] attributes to a decrease in the active cell substance of the body. The persons involved were far from comfortable on the restricted diet; and when the task of a long march was further imposed on them, symptoms of distress ensued. In other words, the scanty maintenance diet of 2,100 calories for an adult man leaves no factor of safety for vigorous physical exercise.

In this country, Benedict[4] and his co-workers at the Carnegie Nutrition Laboratory in Boston have made somewhat analogous, though far more elaborate studies on the effects of a prolonged reduction of diet on twenty-five men. A gradual reduction in weight to a point 12 per cent. below the initial weight took place during a period of from three to ten weeks, with low calories and a moderate amount of protein in the food intake. The normal demand of the men prior to the dietetic alteration ranged from 3,200 to 3,600 net calories. One squad of twelve men subsisted for three weeks on 1,400 net calories without special disturbance. Benedict states that notwithstanding the great reduction in the metabolism (which he believes was due to the removal from the body of the stimulus to cellular activity of approximately 150 gm. of "surplus nitrogen"), the whole period of lowered food intake had no untoward effect on the physical or mental activities of these men, and they were able to continue successfully their college duties. The psychologic report concludes that a prolonged reduction in diet produces some decline in neuromuscular activities, but this does not seem nearly so definite or so large as the changes in metabolism and allied measurements. The psychologic changes were not such as materially to interfere with a satisfactory discharge of the common duties of student life.

Seemingly in contrast to the German experience, Benedict's carefully selected subjects were less distressed by the privations of the diet. The measurement of their metabolism in walking showed a marked saving in the energy requirement for walking in favor of the reduced diet, whether considered on the basis of the gross energy expended, which represents the real cost to the individual and to the national food reservoirs, or on the basis of the energy required per horizontal kilogrammeter. Nevertheless it will be wise, in view of conflicting statements, to hesitate to lower the body weight of the populace at large to any considerable extent by rationing measures for the debated advantage of greater efficiency. The significance of "surplus protein" has not yet been clearly defined.

MORE MILK FOR VITAMINS

More than ten years ago the English physiologic chemist, F. G. Hopkins,[1] had found experimentally that an animal cannot live "on a mixture of pure protein, fat and carbohydrate; and even when the necessary inorganic material is carefully supplied, the animal still cannot flourish." In connection with these investigations he made the important discovery that a surprisingly small amount of milk as well as extracts of some other natural foods confer a nutritive adequacy on the otherwise insufficient ration. Meanwhile Osborne and Mendel[2] in this country demonstrated that the residual part of milk from which its fat and protein had been removed exhibited a growth-promoting or nutrition-promoting property when it was added to mixtures of the purified familiar foodstuffs. Subsequently McCollum and Davis and Osborne and Mendel independently announced that the fat of milk (butter fat) also exerts a further growth-promoting influence presumably due to something different from the known fats but closely associated with them. Thus the significance of the vitamins—a water-soluble and a fat-soluble type, respectively—in milk became established.

These discoveries have since been verified for various species. The lack of either the fat-soluble or the water-soluble essential properties has been believed to lead to distinct pathologic consequences when these vitamins are not replaced from other sources in the diet. Conversely, the presence of these "specifics" for good nutrition and growth contributes in no small measure to make milk the unique food that it is justly regarded to approximate. Hence we can understand what Mrs. Rose[3] intended to imply by this fanciful comment: "When the milk pitcher is allowed to work its magic for the human race, we shall have citizens of better physique than the records of our recruiting stations show today. Even when the family table is deprived of its familiar wheat bread and meat, we may be strong if we invoke the aid of this friendly magician."

Osborne and Mendel[4] have more recently come to the conclusion that from a quantitative standpoint cow's milk is not as rich in the water-soluble vitamin as one not familiar with the experimental evidence for this property of the food might assume. This is in no sense to be construed as a denial of the "magical qualities," but rather as an argument for the more liberal use of milk when it is relied on largely to contribute the growth-promoting factors in the diet. From a practical standpoint it appears not unlikely, to cite the warning of Osborne and Mendel, that the need of children and other growing animals for the water-soluble vitamin, beyond the earlier stages of development when milk admittedly satisfies the nutritive requirements, may not be adequately filled by some of the current or enforced dietary practices. Thus, they add, with a too scanty allowance of milk, a liberal inclusion of products from cereals rendered poor in vitamin by milling, of sugar, fats, and few additional animal products other than meat (which has been shown to contain relatively little of the water-soluble vitamin), it is not surprising if disasters sometimes manifest themselves.

Another aspect of the significance of their quantitative studies of the vitamins in cow's milk has been presented by Osborne and Mendel in relation to milk dilution in infant feeding. It is a common practice to reinforce the supply of calories by diluting top milk and adding lactose. Under these circumstances, we are reminded, the child is supplied with a food that contains a relatively smaller proportion of the water-soluble vitamin than does the original cow's milk. While milk thus modified may contain sufficient vitamin as long as the food intake is normal, if for any reason the child's appetite fails, the vitamin supply is reduced and endless dietary troubles may easily result.

Without attempting to evaluate the actual degree of danger attributable to such causes in the artificial feeding of infants, we may well bear in mind the potentialities for harm. It may be that the young of healthy mothers are born with a reserve supply of the so-called vitamin substances sufficient to maintain them in good nutritive condition until the time when they begin to eat other foodstuffs. If milk is not always as rich in vitamins as is desirable at later stages of growth, there may be real wisdom in the practice of extending the diet as soon as the physiologic conditions of the individual warrant the use of other foods.

Training in Occupation Therapy.—A new course of instruction has been established by Columbia University in the School of Practical Arts in the Teachers' College for the purpose of training women in occupation therapy. The instruction will be given by specialists in nervous and mental diseases. In order to obtain a diploma, seven courses are required, comprising the medical aspects of occupational therapy, the methods of teaching this treatment, observation and practice work with the patients in institutions, the elements of psychology, art structure or design, and at least two craft courses. It is important that those taking up this work be of the normal, wholesome, well balanced type, with vigor and physical endurance. Other requisites for this branch of service are: First, the teacher should understand sick people. In the second place, she should have the psychologic background for teaching, and finally, she should be skilled in the arts and crafts.

Current Comment

VALUE OF VACCINATION AGAINST INFLUENZA

We publish in our Correspondence Department in this issue an interesting letter with the above title. In it the author apparently takes it for granted that the influenza bacillus is the primary cause of the acute epidemic respiratory infection now pandemic and being generally called influenza. There is no conclusive evidence that the Pfeiffer bacillus plays any greater rôle, if as great, in the present epidemic than any other bacteria found in the respiratory tract in this disease. This point emerges very clearly in the abstract of recent English and German literature and in the original contributions printed in this issue. We would also emphasize that, so far as we know, the influenza bacillus is a very poor antigen; there is, in fact, nothing to show that definite antibodies against this bacillus develop in the course of influenza, and the results of animal experiment show that it requires prolonged immunization before any response becomes apparent. Again, we have no record of any properly conducted and controlled experiments on human beings with influenza vaccines. No results of careful observations are as yet at hand. These things being so, what should a fair-minded and thoughtful physician say as to the face value of influenza vaccine? In this connection we give two examples of so-called "evidence" that appeared in newspapers, which seem to be the medium through which most of the evidence is appearing. One appeared in the health department, conducted by a physician, of a metropolitan newspaper in the middle west under the utterly misleading heading "Vaccine Blots Out 'Flu.'" We quote:

> The evidence of the efficiency of the treatment is this: On October 20, about half the population of a town of 10,000 had been vaccinated at least in part. There have been seven cases of the disease. All the cases were among unvaccinated people. In a nearby town, with 400 inhabitants, there have been 200 cases and fifteen deaths. In the asylum three cases developed. Everybody was vaccinated and the disease did not spread. In St. Mary's Hospital the disease got a foothold among the doctors and nurses. After vaccination the disease stopped at once.

The other appears in an eastern paper as an interview with a physician, who, incidentally, is a manufacturer of vaccines, although this vital fact does not appear in the item. Again we quote:

> I think it but just that I should report the success I have had in treating and preventing Spanish influenza with vaccine. I have given over 1,000 inoculations with 100 per cent. protection and treated several hundred cases with no deaths. Prior to the time I used vaccine nearly every one exposed to the disease contracted it. Now I blot it out of every house at my first visit by inoculating the entire family.

This so-called evidence has not yet been submitted in any scientific manner with the necessary facts and details to permit any judgment whatever to be formed as to its true value. In the meantime, we should not forget that in its natural course, epidemic influenza is affecting different, even adjacent, communities with widely varying degrees of severity, and that vaccination in an institution after the disease has appeared can have no value as an experiment because it may have been done in the wane of the epidemic. Finally we repeat: Vaccination against epidemic influenza is in a wholly experimental stage. Nothing can be learned as to its real value from indiscriminate vaccination of the public. The physician who, in view of the severity of the epidemic, feels that he is justified in vaccinating his patients, should be fair to them and protect himself by informing the patient that he regards the procedure as wholly of an experimental nature. Pending developments, nothing should be done by the medical profession that may arouse unwarranted hope among the public and be followed by disappointment and distrust of medical science and the medical profession.

EMERGENCY EDUCATIONAL STANDARDS AND STATE LICENSURE

Thirty-two state licensing boards either in the practice laws or by board rulings require that, before entering on the study of medicine, the student must have completed two years of premedical college work. This requirement as usually interpreted means sixty semester hours of work taken in two annual sessions of nine months each, and usually the two sessions are separated by a summer vacation of three months, making a total in actual time of twenty-two months. Divided into "quarters" of three months each, this would require seven quarters. Now, as noted in The Journal recently,[1] the Committee on Education and Special Training of the War Department has decided not only to do away with the summer vacation but also to condense the work of the remaining six quarters into four, or into a continuous session of twelve months. This means that the student will have to work proportionally harder at his professional studies; but with the rigid military routine there will be more time at his disposal than in the haphazard time-wasting methods of the former régime. The physical exercise required in the eleven hours per week of military drill will help to keep the student physically fit for the extra mental effort required of him. The object hoped for is to secure an equal amount of valuable training in two thirds of the time heretofore spent in obtaining it. The important question for licensing boards to decide is whether they can legally accept this course as the equivalent of the preliminary education required in their respective states, when these students apply for licenses. Based on correspondence conducted by the Council on Medical Education, nearly all the boards that were given ample authority by their practice acts stated their intention to cooperate with the War Department to the fullest extent possible in any measures made necessary by war conditions. In a few other states, amendatory clauses may need to be inserted in the practice acts so as to provide for graduates who began the study of medicine under these special regulations laid down by the War Department. This condensed schedule may, in fact, lead to permanent changes and important improvements both in methods of teaching and in state board requirements. There may, indeed, be an awakening to the fact that much valuable time heretofore has been lost to the student through the adherence to long obsolete arrangements of college curriculums as well as in the time wasted in the long summer vacations. If what has heretofore required six or seven years can be completed in four or five, the two years saved of the average student's time will make some changes in medical license regulations well worth while.

---

PASSING THE INFLUENZA BUCK

The Madrid correspondent of The Journal in his letter in this issue wishes it clearly understood that Spain does not care to take the responsibility for having initiated the present epidemic of respiratory disease. His protestations are both informing and amusing. Our Paris correspondent, also in this issue, feels too that the onus of responsibility should not be placed on Spain since the epidemic occurred both in France and in Germany. As one views the devastation which the disease has caused he is inclined to sympathize with the efforts of Spain or any other country to pass the buck.

ESSENTIAL TEACHERS AND THE DRAFT

Lists of essential teachers have been furnished by deans of well recognized medical colleges to the Surgeon-General of the Army and, as stated in a previous comment,[1] these teachers are not to be commissioned but are being retained at their teaching duties. But this arrangement does not exempt essential teachers of draft age from the requirements of the Selective Service Regulations. Such teachers, therefore, when filing their questionnaires should ask for a deferred classification on the ground that they are engaged in an activity "necessary to the public welfare and to the prosecution of the war." And whether the registrants ask for the deferred classification or not the deans of the medical schools should claim for their essential teachers this deferred classification in accordance with the Selective Service Regulations. While, as stated in one of their extracts, "it shall be the duty of advisers to confer with the managers and heads of various industries"—and this means, also, deans of medical schools—experience shows that the initiative usually has to be taken by the deans of the schools, if their essential teachers are to be retained. And this should be done promptly, since it will be difficult or impossible to get them back after they have once been classified. A ruling recently adopted in the War Department is to the effect that "men heretofore or hereafter classified in Class 1, Group A, and called to military service will not be granted furloughs." The class in which essential teachers of draft age should be placed is Class III-K, which is provided for technicians and experts in necessary industries. Since our medical schools are now practically military institutions in which soldiers on active duty in the U. S. Army are being trained to become efficient medical officers, it is important that the teaching faculties should be kept intact.

RESERVE OFFICERS FOR THE PUBLIC HEALTH SERVICE

Senate Joint Resolution No. 63, establishing a Reserve in the Public Health Service, has finally passed and been approved by the President. It authorizes the President to appoint and commission as officers in the Public Health Service Reserve citizens who, on examination, are found physically, mentally and morally qualified, the commissions to be in force for a period of five years. The officers commissioned shall be distributed in the same proportion as among the present commissioned Medical Corps of the Public Health Service among the several grades now obtaining in that service, namely, Assistant Surgeon-General, Senior Surgeon, Surgeon, Passed Assistant Surgeon, and Assistant Surgeon, which correspond respectively to the grades of Colonel, Lieutenant-Colonel, Major, Captain, and Lieutenant in the Army. Regulations for the organization and government of the Reserve Corps are now being prepared for submission to the President. In view of the manifold activities entrusted by law to the Public Health Service and the expansion of its functions by executive order of July 1, 1918, the new Reserve Corps will include in its membership a personnel with varied qualifications. In addition to physicians who will form the bulk of the reserve this will, therefore, comprise among others, sanitarians, sanitary engineers, chemists and bacteriologists. The passing of this law is another step toward adequate control of national health interests.

THE SEWAGE POLLUTION OF BOUNDARY WATERS

The International Joint Commission on Boundary Waters Between the United States and Canada has recently issued its final report.[1] The conclusions of the commission are based on the best expert knowledge and opinion now available, and will doubtless receive the consideration they deserve. The chief interest in the report centers in the limits of permissible pollution that are established. The commission recognizes that sewage disposal by dilution is a natural resource and that the utilization of this resource is justifiable for economic reasons, always assuming that an unreasonable burden or responsibility is not placed on the water purification plant, so as to occasion menace to the public health. It is believed by the commission that the safe loading of a water purification plant is exceeded if the annual average of *B. coli* in the water delivered to the plant is higher than about 500 per hundred c.c. As a working rule, it has been found that if, under conditions actually existing, the city sewage is diluted in the stream flow to 4 cubic feet per second per capita of the population, the resulting water will contain approximately 500 *B. coli* per cubic centimeter. Perhaps the essence of the report is found in the recommendation that all sewage should receive some purification treatment before being discharged into boundary waters, the degree of such treatment to be determined in large measure by the limit of safe loading of a water purification plant. The report marks a distinct progress in the practical adjustment of sewage disposal necessary to the public welfare.

Medical Mobilization and the War

Resolution to Provide a Reserve Corps for the Public Health Service

A joint resolution to provide a reserve corps for the United States Public Health Service was approved by the President on October 27. The resolution states:

> *Resolved*, by the Senate and House of Representatives of the United States of America in Congress assembled, That for the purpose of securing a reserve for duty in the Public Health Service in time of national emergency there shall be organized, under the direction of the Secretary of the Treasury, under such rules and regulations as the President shall prescribe, a reserve of the Public Health Service. The President alone shall be authorized to appoint and commission as officers in the said reserve such citizens as, upon examination prescribed by the President, shall be found physically, mentally, and morally qualified to hold such commissions, and said commissions shall be in force for a period of five years, unless sooner terminated in the discretion of the President, but commission in said reserve shall not exempt the holder from military or naval service.
>
> *Provided*, That the officers commissioned under this act, none of whom shall have rank above that of Assistant Surgeon-General, shall be distributed in the several grades in the same proportion as now obtains among the commissioned medical officers of the United States Public Health Service and shall at all times be subject to call to active duty by the Surgeon General, and when on such active duty shall receive the same pay and allowances as are now provided by law and regulation for the commissioned medical officers in the said regular commissioned Medical Corps.

Weekly Bulletin, American Expeditionary Forces

The following paragraphs are taken from Weekly Bulletin No. 26, Oct. 7, 1918, issued for circulation among American medical officers in France:

JUDGMENT AND INGENUITY DEMANDED IN TRANSFERRING PATIENTS BETWEEN HOSPITALS

(*a*) Do not transfer patients with pneumonia or respiratory tract infections; absolute rest is as vital to them while they are meeting and overcoming the infection as operation is for penetrating wounds of the abdomen. Patients with infectious diseases while still in the communicable stage should not be transferred.

(*b*) A good many patients with bone and joint injury are being evacuated from one hospital to another either inadequately splinted or entirely without splints. The excuse commonly given is that the standard splints are not available.

Such an excuse is, of course, entirely insufficient, since even though the standard splints are not available, the ingenuity of the surgeon should be used to devise some form of appliance that would be reasonably satisfactory for transport use until the regular splints can be used.

SERIOUS PRESENT SITUATION IN A. E. F.

During the past week there has been further extensive incidence of pneumonia, in almost all instances accompanying the prevailing epidemic of influenza. Large convoys brought to the base ports several thousand cases of severe influenza and many hundreds of cases of pneumonia. The death rate (case mortality percentage) among the pneumonia patients has risen to 32 per cent. for the A. E. F., and in some groups of cases it has been 80 per cent.

When unseasoned men have been sent to the A. E. F., the percentage attacked by influenza on shipboard and the percentage of complicating pneumonias developing among these contingents after arrival has been unusually high, 100 per cent. sick being reported from the Five Hundred and Thirty-Ninth Labor Battalion (Negro).

In addition to the three cardinal causes of high incidence of respiratory affections that still prevail widely (i. e., (1) overcrowding, (2) exposure to wet and cold, and (3) fatigue from overwork, long journeys, loss of sleep, or worry) there has been much pneumonia developing among men with influenza evacuated to base hospitals who should at all costs and by every means possible be kept where they are taken sick. Absolute rest, even though in the absence of skilled nursing, or under very primitive conditions of shelter, is indispensable to escape the complication of pneumonia.

Meningitis has made another sudden rise in incidence, as had been expected. Forty-eight of the seventy-one cases reported in the week were in the base sections, and thirty-three of the cases were found among troops on arrival of a convoy at one port.

Dysentery, diphtheria, measles, paratyphoid, scarlet fever and typhoid fever show a very satisfactory reduction during the week.

Provision for Essential Teachers in Medical Schools

The Committee on Education and Special Training of the War Department has issued the following circular letter relative to furloughs, induction and transfers for the information and guidance of institutions having a unit of the S. A. T. C.:

MEMORANDUM for Commanding Officers, Students' Army Training Corps, and Presidents of Students' Army Training Corps Institutions.
Subject: Policy as to Teachers Registered under Selective Service Act.

1. Men heretofore or hereafter classified in Class 1, Group A, and called to military service will not be granted furloughs.

2. Teachers who are essential are eligible to claim deferred classification under Section 80, Selective Service Regulations, and they are encouraged to do so. Such deferred classification should be claimed for them by the educational institution by which they are employed, in accordance with the paragraphs from Section 80, Selective Service Regulations.

3. Teachers who are denied deferred classification by the district board and who are liable to call to military service will be encouraged to request voluntary induction in the unit of the S. A. T. C. stationed at the institution where such instructors are employed.

4. In very exceptional cases and upon the recommendation of the Educational Department of the Committee teachers who have already been drafted and are now at mobilization camps will be transferred back as soldiers on active duty to the unit of S. A. T. C. where needed; provided such instructors do not object to return as soldier-instructors, have not been permanently assigned in a capacity wherein their services will be of great value to the Army, and have not already been designated to attend Officers' Training Schools.

5. Since the colleges are under contract with the War Department to train enlisted men in the U. S. Army, essential teachers are obviously engaged in occupations that are strictly "necessary to the maintenance of the Military Establishment." It is, therefore, expected that the really essential professors and teachers will be granted deferred classification under the law on this account. Heads of institutions should see to it that district boards and their industrial advisers are fully informed of all the facts in every case.

By direction of the Committee.

R. I. Rees,
Colonel, General Staff Corps Chairman.

October 1, 1918.

COMMISSIONS OFFERED AND ORDERS TO DUTY ON ACCEPTANCE

Alabama

To Camp Beauregard, La., Lieuts. C. E. FORD, Roanoke; R. D. PORCH, Sylacauga.

To Camp McClellan, Ala., Lieut. J. W. GWIN, Bessemer.

To Camp Sheridan, Ala., Lieut. D. H. Chilton, Patton. Base hospital, for instruction, Lieut. W. B. HARDY, Birmingham.

To Camp Wheeler, Ga., Lieut. D. R. CORNELIUS, Pratt City.

To Fort Oglethorpe for instruction, Capts. W. M. WALDRUP, Bessemer; W. S. SOWELL, Empire; W. M. BOOTH, Hartsells; Lieuts. T. COLLINS, Birmingham; E. S. PRICE, Buhl; H. F. DOWNS, Clanton; G. H. SMITH, Ensley; W. D. MIXSON, Midland City.

To report to the commanding general, Southeastern Department, Capt. A. A. KIRK, Tuscaloosa; Lieut. E. T. BARKER, McFall.

Arizona

To Fort Oglethorpe for instruction, Capt. R. B. DURFEE, Bisbee.

To Fort Riley for instruction, Lieuts. T. R. WHITE, Kingman; H. W. RICE, Morenci.

To report to the commanding general, Southern Department, Capt. E. C. BAKER, Phoenix.

Arkansas

To Fort Oglethorpe for instruction, Capts. F. E. HARRISON, Fordyce; W. A. MOORE, Rogers.

To Fort Riley for instruction, Capts. O. E. JONES Newport; A. M. ELTON, Yellville; Lieuts. E. R. KING, Ben Lomond; V. V. BUTLER, Huntington; F. YOUNGBLOOD, Huntsville.

To Fort Sam Houston, Texas, Lieut. J. R. DALE, Jr., Texarkana.

California

To Camp Cody, N. M., base hospital, for instruction, Capt. E. J. COOK, Lieut. C. E. REYNOLDS, Los Angeles. *To examine the command* for nervous and mental diseases, Capt. T. J. BERGGREN, Coronado.

To Camp Kearney, Calif., base hospital, for instruction, Lieuts. C. N. MOONEY, Blue Lake; F. W. WATT, Sacramento; M. H. ARNOLD, San Diego; H. F. ADLER, San Francisco; H. E. TEBBETTS, Whittier.

To Denver, Colo., Lieut. J. W. NEVIUS, Los Angeles.

To Fort Oglethorpe for instruction, Capt. W. S. VAN DALSEM, San Jose.

To Fort Riley for instruction, Lieut. H. C. SMITH, Glendale.

To report to the commanding officer, Western Department, Capt. J. M. WARD, Oakland; Lieuts. E. G. BASHOR, Los Angeles; H. ABRONS, Napa.

To San Francisco, Calif., Letterman General Hospital, for instruction, Capt. W. A. RECKERS, Placerville; Lieut. J. S. MASON, Ventura.

Canal Zone

To Fort McPherson, Ga., Lieut. L. WENDER, Corozal.

Colorado

To Azalea, N. C., Capt. G. H. CATTERMOLE, Denver.

To Camp Dodge, Iowa, base hospital, for instruction, Lieut. I. C. MIERLEY, Denver.

To Camp Logan, Texas, Capt. D. C. GROVES, Olathe.

To Fort Oglethorpe for instruction, Capts. C. F. EAKINS, Brush; H. R. McGRAW, Denver.

To Fort Riley for instruction, Lieuts. L. W. SOLAND, Blanca; P. A. WATERS, Monte Vista.

To Whipple Barracks, Ariz., Capt. A. G. WALKER, Denver.

Connecticut

To Camp Joseph E. Johnston, Fla., Lieut. E. J. LYMAN, Hartford.

To Colonia, N. J., Lieut. R. C. PAINE, Thompson.

To Fort Oglethorpe for instruction, Lieut. J. J. TYNAN, Torrington.

To New Haven, Conn., Capt. H. W. FLECK, Bridgeport. Yale Army Laboratory School, for instruction, Lieut. C. T. BEACH, Hartford.

To New York, Neurological Institute, for instruction, Lieut. T. W. WORTHEN, Hartford.

District of Columbia

To Camp McClellan, Ala., base hospital, Lieut. C. B. CONKLIN, Washington.

Florida

To Camp Meade, Md., Lieut. B. H. SANCHEZ, Plant City.

To Fort Oglethorpe for instruction, Lieut. R. E. CHALKER, Live Oak.

Georgia

To Fort Oglethorpe for instruction, Lieuts. W. H. ALEXANDER, Blakely; H. H. BLAKE, Savannah.

Idaho

To Fort Riley for instruction, Capts. H. D. SPENCER, Idaho Falls; H. E. MELTON, Menan; Lieuts. H. J. SIMMONS, Blackfoot; A. A. NEWBERRY, Filer; G. T. PARKINSON, Rexburg.

To report to the commanding general, Western Department, Capts. E. H. FIELD, Jerome; C. P. STACKHOUSE, Sandpoint.

Illinois

To Camp Beauregard, La., base hospital, for instruction, Capt. S. G. WEST, Chicago.

To Camp Custer, Mich., Lieut. R. V. SPENCER, Chicago Heights.

To Camp Dodge, Iowa, base hospital, for instruction, Capt. F. J. LESEMAN, Chicago.

To Camp Grant, Ill., Capt. C. E. SCELETH, Chicago. Base hospital, for instruction, Lieuts. H. O. JONES, Chicago; R. O. HAWTHORNE, Monticello.

To Camp Pike, Ark., Lieuts. P. B. JOYCE, Chicago; J. P. O'NEILL, Highland Park. *To examine the command* for nervous and mental diseases, Capt. W. A. CROOKS, Peoria.

To Camp Sherman, Ohio, Lieut. E. W. MUELLER, Chicago.

To Camp Wheeler, Ga., base hospital, Lieut. E. A. STREICH, Chicago.

To Camp Zachary Taylor, Ky., Capt. B. F. FLANAGAN, Lieut. M. SOLOMON, Chicago. *To examine the command* for nervous and mental diseases, Lieut. A. H. WATERMAN, Chicago.

To Fort Des Moines, Iowa, Lieuts. R. B. KERSHAW, M. O'HEARN, Chicago.

To Fort Oglethorpe for instruction, Capts. S. W. SHURTZ, Champaign; F. H. BLAYNEY, R. C. CUPLER, F. P. MACHLER, A. W. McCLAVE, J. M. NICHOLSON, Chicago; G. STEELY, Danville; A. L. HAGLER, Springfield; Lieuts. F. C. BAECHT, Brussels; H. W. J. KOERPER, Buda; F. G. CARLS, E. S. CLEVELAND, C. H. CONNOR, W. S. CROWLEY, E. H. FLINN, A. W. GREGG, W. P. GUNN, H. C. HANSON, E. L. HESS, F. C. JACOBS, F. E. MILLER, J. H. MITCHELL, V. V. PISANI, H. C. RUNYAN, G. E. SANDSTEDT, F. M. SCHWARZEL, R. W. E. SPRENG, Chicago; B. L. VILNA, Cicero; C. O. BULGER, Greenfield; E. G. MERWIN, Highland;; E. F. SCHEVE, Mascoutah; W. L. COTTINGHAM, Paxton; M. T. EASTON, Peoria; C. T. KELL, Salem; J. G. MEYER, Springfield; T. G. KNAPPENBERGER, St. Joseph; A. H. HUNTER, Staunton; A. J. FROELICH, West McHenry.

To Fort Riley for instruction, Capts. C. G. DAVIES, Blue Island; S. WAYLAND, Chicago; E. L. DAMRON, Effingham; L. H. TATE, Galesburg; T. E. McCALL, Vienna; Lieuts. A. TRIPODI, Benld; J. H. GAFF, O. B. FUNKHOUSER, A. MAGNUS, Chicago; G. HENDERSON, Clay City; C. M. COOK, J. L. FUNKHOUSER, Danville; F. E. HAGIE, Elizabeth; R. D. FINCH, Flora; M. L. HARTMAN, Garden Prairie; R. L. WATSON, Joliet; C. E. ERICSON, Quincy; C. H. BOSWELL, Rockford; W. E. COULTER, Seneca; J. E. MARVEL, Waynesville; S. W. BROWNSTEIN, Westville.

To report to the commanding general, Central Department, Capt. T. R. FOSTER, Watseka; Lieuts. C. P. GIERALTOWSKI, Chicago; H. C. McMILLIN, Morton.

Indiana

To Camp Custer, Mich., Capt. H. W. SIGMUND, Crawfordsville.

To Camp Greene, N. C., to examine the command for nervous and mental diseases, Capt. H. D. PURDUM, Sykesville.

To Camp Zachary Taylor, Ky., Lieut. R. M. FUNKHOUSER, Evansville.

To Colonia, N. J., Capts. J. A. CRAIG, Gary; G. D. KIMBALL, Marion.

To Fort Oglethorpe for instruction, Capts. J. B. STALKER, Borden; L. C. BICE, Edinburgh; G. S. BEATY, French Lick; J. J. BOAZ, W. B. KITCHEN, O. C. NEIER, Indianapolis; J. E. BIRD, New Albany; Lieuts. E. D. HAVENS, Cicero; T. D. PETERS, Flora; J. P. CHRISTIE, F. W. MAYER, H. F. NOLTING, Indianapolis; E. C. CEKUL, La Otto; E. BARNUM, Manilla; G. V. CRING, Portland; O. T. BRAZELTON, Princeton; F. E. BASS, Shelbyville; D. E. MURRAY, Sheldon.

To Fort Riley for instruction, Capts. R. S. CHAPPELL, W. F. KELLY, Indianapolis; Lieuts. H. S. HIATT, Albion; S. M. COMPTON, Forest; A. H. HENDRICKS, W. H. LONG, Indianapolis; W. I. SCOTT, Kokomo; P. T. GRANT, Marengo; F. T. TYLER, New Albany.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Lieut. R. E. COLE, Muncie.

To report to the commanding general, Central Department, Capt. W. G. HUFFMAN, Richmond; Lieut. J. F. DRAKE, Youngstown.

Iowa

To Camp Dodge, Iowa, base hospital, for instruction, Capt. C. E. GLYNN, Davenport; Lieut. J. A. CAHILL, Volga City. *To examine the command* for nervous and mental diseases, Lieut. F. J. VAN METER, Clarinda.

To Camp Shelby, Miss., base hospital, for instruction, Lieut. F. A. GILLETT, Fremont.

To Camp Wheeler, Ga., base hospital, Capt. J. L. SEABLOOM, Red Oak.

To Fort Oglethorpe for instruction, Lieuts. J. H. WOLFE, Iowa City; W. G. ROWLEY, Sioux City.

To Fort Riley for instruction, Capts. W. C. PHILLIPS, Clarinda; S. D. CARNEY, Sioux City; Lieuts. J. D. PAUL, Anamosa; D. F. HUSTON, Columbus Junction; G. D. CLEAVER, Council Bluffs; T. D. JACOBS, Morley; N. W. LABAGH, Mystic; W. C. CUMMINGS, Ryan.

To report to the commanding general, Central Department, Capt. J. O. GANOE, Ogden; Lieut. E. B. HADLEY, Waterloo.

Kansas

To Camp Dodge, Iowa, base hospital, for instruction, Capt. W. A. KLINGBERG, Elmo.

To Camp Logan, Texas, Capt. J. B. CARTER, Wilson.

To Camp Pike, Ark., base hospital, Lieut. R. G. SMITH, Marion.

To Fort Oglethorpe for instruction, Capts. J. S. McBRIDE, Lyon; H. E. NELSON, Sharon Springs.

To Fort Riley for instruction, Lieuts. C. F. ATWOOD, Abilene; W. W. SCOTT, Athol; G. E. MARTIN, Callison; A. W. CORBETT, Emporia; M. L. BRAKEBILL, Florence; F. L. DEPEW, Howard; D. J. MOORE, Idana; P. L. JONES, Lenexa; J. W. DEMAND, Lincolnville; H. W. DAVIS, Little River; F. R. BLAKE, Marquette; O. M. CASSEL, Norton; W. O. POSTON, Quenemo; T. A. O'CONNOR, C. S. WOLFE, Topeka; E. S. HAWORTH, Viola; E. A. MYERS, Wakefield.

Kentucky

To Camp Sevier, S. C., Lieut. T. J. ROBB, North Fork.

To Fort Oglethorpe for instruction, Capts. H. C. WHITE, Covington; H. L. McLEAN, Wilmore; Lieuts. H. V. JOHNSON, Georgetown; A. BACH, Jackson; T. M. DORSEY, I. N. KERNS, Louisville; L. O. PINDAR, Tyronne; W. G. SHACKLETTE, Valley Station.

To New York, Neurological Institute, Capt. E. T. BRUCE, Louisville.

To report to the commanding general, Central Department, Capt. W. T. McKINNEY, S. P. MYER, Louisville.

Louisiana

To Camp Beauregard, La., base hospital, for instruction, Lieut. E. L. SANDERSON, Shreveport.

To Camp Bowie, Texas, base hospital, Lieut. W. M. JOHNSON, New Orleans.

To Camp Custer, Mich., Lieut. P. C. SCHMIDT, New Orleans.

To Camp Jackson, S. C., base hospital, for instruction, Capt. R. E. Stone, New Orleans.

To Camp Joseph E. Johnston, Fla., Lieut. L. CHATELAIN, Hessmer.

To Fort Oglethorpe for instruction, Capts. E. F. BACON, E. L. LECKERT, New Orleans; Lieuts. J. K. SHEPPARD, Houghton; E. BLOCH, H. E. MILLER, E. S. SCHARFF, New Orleans.

Maine

To Camp Jackson, S. C., base hospital, for instruction, Capt. D. B. CRAGIN, Waterville.

To Camp Upton, N. Y., Lieut. C. G. FARRELL, Gardiner.

To Mineola, N. Y., Capt. S. E. FISHER, Portland.

To Norfolk, Mass., Lieut. K. B. STURGIS, Fairfield.

To report to the governor of Maine, as Medical Aide, Capt. H. F. BRADBURY, Norway.

Maryland

To Camp Lee, Va., for instruction, Capt. P. L. TRAVERS, Easton.

To Camp Meade, Md., Lieut. A. STEIN, Baltimore.

To Camp Wadsworth, S. C., to examine the command for nervous and mental diseases, Lieut. W. S. CARSWELL, Ruxton.

To Fort Oglethorpe for instruction, Capt. J. S. WILLOCK, Roland Park; Lieuts. F. H. CLARK, W. O. WHITTLE, W. F. ZINN, Baltimore; W. A. GRACIE, Cumberland; B. I. JAMISON, Emmitsburg.

Massachusetts

To Arcadia, Fla., Carlstrom Field, Lieut. W. D. STACEY, Boston.

To Camp Devens, Mass., Lieut. W. E. HUNT, Bridgewater. Base hospital, Capts. G. H. STONE, Boston; O. M. DEEMS, Springfield; Lieut. W. W. HENNESSEY, Salem. Base hospital, for instruction, Capt. D. P. O'BRIEN, New Bedford; Lieuts. T. A. DEVAN, L. E. PHANEUF, Boston.

To Camp Jackson, S. C., base hospital, Lieut. C. H. LAWRENCE, Jr., Boston.

To Camp Lee, Va., Capt. H. M. CHASE, Boston. Base hospital, for instruction, Capts. H. H. GERMAIN, Boston; G. M. SHEAHAN, Quincy. For instruction, Lieut. C. A. ORDWAY, Everett.

To Camp Meade, Md., Lieuts. A. R. CUNNINGHAM, Boston; H. KAPLOVITCH, Haverhill.

To Camp Upton, N. Y., Lieut. M. F. McMAHON, Worcester.

To Colonia, N. J., Capt. J. E. OVERLANDER, Springfield.

To Fort Oglethorpe for instruction, Capts. A. H. RING, Arlington Heights; S. F. CURRAN, L. B. MORRISON, Boston; W. B. YOUNG, East Cambridge; F. D. McALLISTER, Lawrence; S. S. ORR, West Lieuts. G. H. BINNEY, E. S. BISBEE, R. P. BONELL, W. E. CONNOLLY, J. G. HEGARTY, Z. A. MOLLICA, E. H. ROBBINS, J. L. SULLIVAN, Boston; J. D. TAYLOR, East Boston; W. H. SHER-

MAN, Graniteville; J. E. GRADY, Leominster; F. C. CASSIDY, Medford; C. SHANKS, New Bedford; G. A. WILKINS, Revere; E. A. GENEREAUX, Whitinsville; L. K. CROSS, Winchendon; J. P. CARROLL, Woburn; F. B. PUSKINIGIS, Worcester.

To Hoboken, N. J., Lieut. E. F. REGAN, Framingham.

To Lakewood, N. J., Lieut. T. E. BUCKMAN, Boston.

To Mineola, N. Y., Hazelhurst Field, for instruction, Capt. F. E. DOW, Northampton; Lieut. T. F. CAPELES, Haverhill.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Capt. D. L. WILLIAMS, Boston; Lieuts. J. E. WATERS, Gardner; J. A. RUEL, Haverhill.

To report to the commanding officer, Northeastern Department, Capt. V. A. REED, Lawrence; Lieut. N. M. CROFTS, North Adams.

Michigan

To Camp Custer, Mich., Lieut. M. P. FISHER, Detroit. Base hospital, Capt. J. T. S. HAMILTON, Detroit; Lieut. P. VERMEULEN, Grand Rapids.

To Camp Zachary Taylor, Ky., base hospital, Lieut. C. S. KLOEPPEL, Detroit. Base hospital, for instruction, Lieut. E. I. CARR, Lansing.

To Colonia, N. J., Lieut. W. M. BURLING, Grand Rapids.

To Fort Oglethorpe for instruction, Capts. J. J. DELBRIDGE, Detroit; J. B. BROWN, Lavering; C. W. MERRITT, St. Joseph; Lieuts. W. S. CHAPIN, Ann Arbor; H. P. LAWRENCE, Bay City; A. L. HAIGHT, Crystal Falls; T. H. E. BEST, C. W. COURVILLE, R. S. MacKNIGHT, M. B. ROBINSON, Detroit; C. E. LONG, Grand Haven; V. L. OLER, Kearsarge; D. A. GALBRAITH, Lansing; G. F. LAMB, Pentwater; J. D. BRADFIELD, Portland; I. L. HUNT, Scottville; F. R. BURDENO, Sturgis.

To Fort Porter, N. Y., Lieut. F. C. BANDY, Newberry.

To report to the commanding general, Central Department, Capt. J. H. KIMBLE, Plymouth.

Minnesota

To Camp Custer, Mich., base hospital, for instruction, Lieut. T. L. CHAPMAN, Duluth.

To Camp Dodge, Iowa, base hospital, Capt. A. E. SMITH, Minneapolis.

To Camp Grant, Ill., base hospital, for instruction, Lieuts. F. F. MOREHOUSE, Owatonna; W. O. OTT, Rochester. For instruction, Capts. S. B. HAESSLY, Fairbault; I. SIVERTSEN, Minneapolis.

To Fort Oglethorpe for instruction, Capts. J. W. DOYLE, Minneapolis; W. W. HIGGS, Park Rapids; Lieuts. C. J. GOODHEART, Akeley; H. F. RAWLINGS, Eveleth; A. L. HAMEL, Minneapolis; G. A. MURRAY, Rochester.

To Fort Riley, Capt. T. THORDARSON, Minnesota. For instruction, Capt. W. P. LEE, Northfield; Lieuts. C. D. KOLSET, Benson; E. E. CRESS, Boyd; A. E. PHILLIPS, Delano; M. W. H. BECKMAN, H. LYSNE, C. L. RODGERS, Minneapolis.

Mississippi

To Camp Beauregard, La., Lieut. J. E. FURR, Belen.

To Fort Oglethorpe for instruction, Capts. J. S. JACKSON, Belzoni; J. E. WALLACE, Biloxi; Lieuts. R. E. GRAY, Bude; H. L. MAINS, Danvers; C. W. MITCHELL, Harkville; S. W. COLEY, Reid; W. D. COPELAND, Sandersville.

To report to the commanding officer, Southern Department, Capt. J. B. MOONEY, Scooba.

Missouri

To Camp Beauregard, La., Lieut. M. E. HAGERTY, St. Louis.

To Camp Dix, N. J., base hospital, Lieut. E. J. SCHISLER, St. Louis.

To Camp Dodge, Iowa, base hospital, Lieut. C. A. REVELLE, Kansas City.

To Camp Pike, Ark., Capt. W. R. SUMMERS, Springfield; Lieut. O. HOFMANN, Kansas City.

To Camp Shelby, Miss., base hospital, for instruction, Capt. E. L. DORSETT, St. Louis.

To Fort Oglethorpe for instruction, Capts. G. O. HAMMERSLEY, Campbell; E. P. PORTERFIELD, St. Louis; Lieuts. W. C. INGRAM, Browning; T. R. GAMMAGE, F. P. HERBST, Kansas City; P. L. PATRICK, Marceline; S. F. WEYGANDT, St. Louis.

To Fort Riley, Capt. H. L. REID, Charleston. For instruction, Capts. J. J. FARRELL, C. E. PAXON, Hannibal; J. S. SNIDER, Kansas City; F. L. McCORMICK, Moberly; T. A. ROSELLE, Palmyra; H. R. CLARK, Peirce City; W. C. PROUD, St. Joseph; S. T. BASSETT, C. N. GUHMAN, St. Louis; Lieuts. P. H. STOCKFLETH, Cameron; E. L. PARKER, Excelsior Springs; W. PIERCE, Forrest Park Heights; A. M. UNDERWOOD, Holstein; O. A. GROTE, Moberly; E. W. SULLIVAN, Osceola; C. D. OSBORNE, Otterville; H. H. FRANCIS, St. Joseph; J. DAVIE, P. A. ECK, A. A. WERNER, St. Louis; L. L. HENSON, West Eminence.

To report to the commanding officer, Central Department, Capt. M. B. AUSTIN, Brunswick; Lieut. W. H. ABER, Aullville.

Montana

To Fort Oglethorpe, Lieut. P. E. KANE, Butte. For instruction, Lieut. H. G. HARRIS, Poplar.

To Fort Riley for instruction, Lieut. W. B. SHORE, Red Lodge.

Nebraska

To Camp Dodge, Iowa, base hospital, for instruction, Lieut. O. H. HAHN, Hastings.

To Fort Oglethorpe for instruction, Lieuts. L. L. NELSON, Norfolk; L. A. DERMODY, Omaha; L. B. LAKE, Wausa.

To Fort Riley, Capt. W. R. McGREW, Omaha. For instruction, Capts. E. C. STEVENSON, Gothenburg; J. E. SIMPSON, Omaha; Lieuts. J. B. REDFIELD, North Platte; R. S. JOHNSTON, Omaha; J. R. LEIBEE, Polk; J. W. STOCKMAN, Red Cloud.

New Hampshire

To Colonia, N. J., Capt. G. H. PARKER, Hanover.

New Jersey

To Camp Dix, N. J., base hospital, Capt. W. S. BRANNER, Hoboken.

To Camp Meade, Md., Capt. O. B. DUNCAN, Paterson; Lieut. J. A. CONNELLY, Trenton.

To Fort Oglethorpe for instruction, Capts. H. ARBUCKLE, Boonton; J. V. BERGIN, Paterson; Lieuts. W. R. RIECK, Arlington; J. J. REASON, Garteret; E. W. MIERAU, Irvington; F. C. SHIPMAN, Jersey City; G. L. JOHNSON, Morristown; W. E. McCORMICK, Mount Vernon; J. J. SMITH, H. R. VAN NESS, Newark; W. E. WAKELEY, Orange; A. A. BUTTERFIELD, Passaic.

To Mineola, N. Y., Hazelhurst Field, for instruction, Capt. A. B. RUSSELL, East Orange.

To Plattsburg Barracks, N. Y., Lieut. M. A. CURRY, Greystone Park.

New Mexico

To Camp Cody, N. M., base hospital, Lieut. S. C. CLARKE, Albuquerque.

To Fort Riley for instruction, Lieuts. H. A. STROUP, Artesia; H. J. HOAG, Mora.

To New Haven, Conn., Yale Army Laboratory School, for instruction, from Fort McPherson, Lieut. P. A. MURR, Galion.

To report to the governor of the Panama Canal, Lieut. L. W. GORTON, Cincinnati.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Dix, N. J.*, base hospital, for instruction, from Fort Oglethorpe, Lieut. G. F. BARNETT, Painesville.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. A. F. SNELL, Jr., Cincinnati.

The following order has been revoked: *To Fort Oglethorpe* for instruction, Major C. A. L. REED, Cincinnati.

Oklahoma

To Camp A. A. Humphreys, Va., from Camp Grant, Lieuts. B. W. BAKER, Cloudchief; F. MOSLEY, Millerton.

To Camp Crane, Pa., Evacuation Ambulance Company, from Fort Riley, Capt. K. L. COLLEY, Bigheart.

To Fort Hamilton, N. Y., from Camp Grant, Lieut. A. S. SPANGLER, Pauls Valley.

To Fort Riley for instruction, Lieut. A H. LARSKOW, Claremon.

Honorably discharged, Capt. H. D. SHANKLE, Hastings. On account of physical disability existing prior to entrance into the service, Lieut. R. A. WORKMAN, Woodward.

Oregon

To Camp Crane, Pa., Evacuation Ambulance Company, from Fort Riley, Lieut. H. H. HUGHES, Gresham.

To Camp Jackson, S. C., base hospital, from Fort Oglethorpe, Capt. H. G. PARKER, Portland.

Pennsylvania

To Camp Colt, Pa., from Camp Dix, Lieut. F. D. LOHR, Derry.

To Camp Crane, Pa., from Camp Custer, Capt. W. F. ROSS, Aspinwall; from Fort Oglethorpe, Capt. J. B. ROGERS, Pottsville.

To Camp Gordon, Ga., base hospital, from Fort Oglethorpe, Lieut. R. L. ANDERSON, Pittsburgh.

To Camp Meade, Md., evacuation hospital, from the Surgeon-General's Office, Capt. W. J. EZICKSON, Philadelphia.

To Fort Oglethorpe, base hospital, from Fort McPherson, Lieut. J. O. BOWER, Wyncote.

To Hoboken, N. J., from Camp Meade, Lieut. P. K. HELLER, Dixmont.

To Newport News, Va., from Fort Oglethorpe, Lieut. L. LASDAY, Pittsburgh.

To New York, Neurological Institute, for instruction, Lieut. M. McCUTCHEON, Philadelphia.

To Richmond, Va., from Camp Dix, Capt. J. M. TIMMONS, West Alexander.

To Rockefeller Institute for instruction in the treatement of infected wounds, and on completion to Camp Meade, Md., base hospital, for instruction, from Fort Oglethorpe, Capt. W. T. ELLIS, Jr., Philadelphia.

Honorably discharged on account of physical disability existing prior to entrance into the service, Capt. W. S. RUCH, Carlisle; W. A. LAROSS, McDonald; Lieut. W. R. McCLELLAN, Garrett.

Resignation of Lieut. E. P. DAVIS, Philadelphia, accepted.

South Dakota

To Fort Riley for instruction, Lieut. W. E. DONAHOE, Sioux Falls.

To Hoboken, N. J., base hospital, Lieut. G. E. VAN DEMARK, Sioux Falls.

Tennessee

To Camp Crane, Pa., evacuation hospital, from Fort Oglethorpe, Capt. J. H. KING, Nashville.

To report to the commanding general, Central Department, from Fort Riley, Lieut. E. C. MASON, Bon Air.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. O. M. LATEN, Memphis.

Texas

To Camp Crane, Pa., from Camp MacArthur, Major W. M. WOLF, San Antonio; from Camp McClellan, Capt. I. A. WITHERS, Fort Worth. Evacuation Ambulance Company, from Fort Riley, Lieut. O. HUFF, Castell.

To Camp Hancock, Ga., base hospital, from Fort Oglethorpe, Lieut. S. ISRAEL, Houston.

To Camp McClellan, Ala., base hospital, from Corpus Christi, Lieut. H. F. WILKINS, Fort Worth.

To Fort Oglethorpe for instruction, Lieut. L. H. LANIER, Texarkana.

To Newport News, Va., from Fort Oglethorpe, Capt. G. F. ST. JOHN, Harriman.

To report to the commanding general, Southern Deparment, Lieut. E. A. BENBOW, Luling.

To Walter Reed General Hospital, D. C., from Fort Oglethorpe, Lieut. R. E. HILBURN, Antelope.

Honorably discharged on account of physical disability existing prior to entrance into service, Capts. J. L. WOMACK, Edna; J. A. HARDY, El Paso; Lieut. J. A. MOORE. Jourdanton.

Utah

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. E. A. WEYMULLER, Geneva.

Virginia

To Camp Crane, Pa., base hospital, from Fort Oglethorpe, Capt. P. W. BOYD, Winchester.

To Fort Benjamin Harrison, Ind., from Fort Oglethorpe, Capt. M. C. SYCLE, Richmond.

To Fort Monroe, Va., from Camp Lee, Lieut. M. GROVEHAGEN, Richmond.

To Hoboken, N. J., evacuation hospital, from Camp Pike, Lieut. E. M. HICKS, Jr., Roanoke.

Washington

To Camp Crane, Pa., Evacuation Ambulance Company, from Fort Riley, Capt. F. M. CROSBY, Kennewick.

To Camp Dodge, Iowa, base hospital, from Fort Oglethorpe, Capt. L. B. BALDWIN, Seattle.

To Mineola, N. Y., Hazelhurst Field, for instruction, from Vancouver Barracks, Lieut. J. D. BARNWELL.

West Virginia

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. W. E. WHITESIDE, Harrisville.

Wisconsin

To Camp Crane, Pa., Evacuation Ambulance Company, from Fort Riley, Capt. E. A. KETTERER, Montford.

To Newport News, Va., from Fort Oglethorpe, Lieut. W. J. MURPHY, Milwaukee.

Honorably discharged, Lieut. M. A. FRONEY, Racine. On account of physical disability existing prior to entrance into the service, Capt. A. M. FOSTER, Racine.

Wyoming

To Camp Crane, Pa., Evacuation Ambulance Company, from Fort Riley, Lieut. W. LOWE, Sunrise.

To Fort Oglethorpe for instruction, Major E. M. TURNER, Laramee.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Sen. Surg. G. A. Magruder, proceed to Washington, D. C., for conference regarding venereal disease control.

Surg. W. C. Billings, proceed to various cities in state of California to investigate the public health value of certain contemplated improvements.

Surg. E. A. Sweet, proceed to certain points in the states of North Dakota, South Dakota, Colorado, Nebraska and Kansas for conference regarding measures for influenza control.

Passed Asst. Surg. W. M. Jones, proceed to League Island Navy Yard for inspection of repairs for steamer *Neptune*.

Asst. Surg. R. E. Dyer, proceed to Englewood, New Jersey, and assume charge of Service operations in extra-cantonment sanitation.

Asst. Surg. M. C. Edmunds, relieved from further duty in the District of Columbia and proceed to Madison, Wis., for duty in measures for the control of influenza.

Acting Asst. Surg. Orlando Ducker, proceed to Richmond, Va., for duty in control of influenza.

Acting Asst. Surg. John W. Goltra, proceed to Elkins, W. Va., for duty in connection with the control of influenza.

Acting Asst. Surg. M. D. Hollis, proceed to Tampa Bay Quarantine Station and assume charge of the Service.

Acting Assst. Surg. J. T. McDonald, proceed to Kalawao, Hawaii, for the purpose of supervising leprosy investigation at that place.

Acting Asst. Surg. A. J. McLaughlin, proceed to Lincoln, Neb., to address the druggist convention at that place.

Acting Asst. Surg. Evelyn G. Mitchell, proceed to Harrisburg, Pa., for duty in connection with the control of influenza.

Acting Asst. Surg. B. F. Roberts, proceed to Madison, Wis., for duty in connection with the control of influenza.

Acting Asst. Surg. Julius Schiller, proceed to Harrisburg, Pa., for duty in the control of influenza.

Pharm. F. S. Goodman, proceed to the Marine Hospital, Louisville, Ky., for duty.

San. Engr. H. W. Streeter, proceed to Bethlehem, Pa., for the investigation of public health needs of certain contemplated improvements.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Masks Compulsory.—During the height of the influenza epidemic in San Francisco in the latter part of October, by a proclamation of Mayor Rolph all citizens were required to wear masks in all places where they come in contact with others, whether on the street or on the inside of business or other places. Strict orders were given to the police to enforce the regulation.

ILLINOIS

Correspondence Schools Closed.—The International College of Osteopathy, the Columbia College of Chiropractic and the Illinois College of Somapathy, correspondence schools, heretofore located at Elgin, are reported to have closed and to be about to surrender their charters.

Physician Gives Home for Negroes.—Dr. William E. Quine, Chicago, is reported to have deeded his residence at 3160 Indiana Avenue, to the Chicago Home Missionary and Church Extension Society of the Methodist Episcopal Church, to be used as a social center for negroes.

Illegal Practitioner Fined.—A raid on one of the offices and medical museums said to be backed by Emil Hellisher, Hammond, Ind., was made at Joliet, recently. M. A. Chaiken, assistant registered pharmacist, is said to have been fined $75 and costs for practicing medicine without a license.

Personal.—Dr. H. Gideon Wells, Chicago, is leaving in a few days for the Balkan States, as a member of the Balkan Commission of the American Red Cross.——Dr. Graham M. Lisor, East Moline, formerly a member of the staff of the Elgin State Hospital, has been appointed superintendent of the St. James (Minn.) Hospital and Sanitarium.——Lieut.-Col. Philip Schuyler Doane, M. C., U. S. Army, Chicago, head of the Health and Sanitation Division, Industrial Relations Group, U. S. Shipping Board, Emergency Fleet Corporation, will, it is reported, sail for France, next month, to assume command of an evacuation hospital.——Lieut.-Col. Edmund J. Doering, M. C., U. S. Army, Chicago, is reported to have been appointed district medical officer, Personnel Branch, Operations Division, of the General Staff.

INDIANA

License Revoked.—The license to practice medicine in Illinois, of Dr. Edward D. Porter, Indianapolis, is said to have been revoked, October 15.

Personal.—Dr. Charles C. Morris, Rockville, is reported to be critically ill with influenza.——Dr. Hugh D. Wood, Angola, is said to be seriously ill at his home.

Mental Hygienists to Meet.—The third annual meeting of the Indiana Society of Mental Hygiene will be held in Indianapolis, December 16, under the presidency of Dr. William T. Bryan, Bloomington, president of the State University.

MARYLAND

Influenza Ban Lifted.—The influenza ban has been entirely lifted in Baltimore by the health department and schools and colleges have been reopened. The cases reported on the first had dropped to fifty-eight and the deaths to forty-two, and conditions, it is felt, will be normal within the next day or so.

Hospital Train at Chambersburg.—At the request of Surg.-Gen. Rupert Blue of the United States Public Health Service, the Maryland Council of Defense has sent its hospital train to Chambersburg, Pa., where influenza is reported as being very prevalent. The train has been at Cumberland and other points in western Maryland. Conditions throughout the state have improved to such an extent that the train is no longer needed in the counties.

Personal.—Capt. George L. Stickney, Baltimore, of the U. S. Army Medical Corps, formerly from Baltimore, who was severely injured at the battle of Soissons, has entirely recovered and has been transferred to new duty. He is now serving in a replacement camp with U. S. Military Hospital No. 47.——Rear Admiral Albert M. D. McCormick, veteran medical officer at the Naval Academy, has received orders to proceed to duty with the naval forces overseas. Admiral McCormick has been on duty at Annapolis almost continuously for more than a score of years.

MASSACHUSETTS

Increased Pay for Medical Examiners.—The legislative action authorizing the city of Boston to increase the salaries of medical examiners, George B. Magrath and Timothy Leary and their assistants, was accepted by the council, September 23. By the provision of this act, Drs. Magrath and Leary will receive a salary of $6,000 instead of $4,500 as heretofore.

Personal.—Dr. John J. Carroll, Holyoke, acting assistant surgeon, U. S. P. H. S., has been appointed chief of the subdivision of venereal diseases of the state department of health, to succeed Major Alec Nicol Thomson, who was placed in charge of the work of correlating the efforts against the venereal diseases in behalf of both the Army and Public Health Service.——Dr. Lily Owen B. Burbank, East Bridgewater, has been appointed director of educational work for the women of the subdivision of the venereal disease of the state department of health.——Dr. Esther M. E. Sundelor, Fall River, roentgenologist at the Truesdale Hospital and Clinic, Fall River, has returned to her work after a summer spent at St. Anthony Hospital, Labrador.——Dr. Charles H. Winn, Roxbury, Boston, has been appointed high medical examiner of the Massachusetts Catholic Order of Foresters.

Massachusetts Health Committee.—During the summer there was organized a health committee to conduct a health campaign in the state, under the auspices of Dr. Eugene R. Kelley, state commissioner of health. This committee will work along educational lines and will carry on a vigorous campaign of lectures, exhibits, newspaper publicity and circular work. The committee will act in advisory capacity to less experienced organizations, and will aim to be "a clearing-house for public health ideas." The officers of the committee are Dr. Eugene R. Kelley, chairman; Miss Gertrude W. Peabody of the Child's Welfare Department, Council of National Defense, treasurer; Prof. Charles E. Bellatty of Boston University, director of publicity; Bishop William Lawrence, representing the Society of Social Hygiene; Dr. Edward Reynolds, Boston, director of the American Society for the Control of Cancer; Dr. George M. Kline, Boston, director of the Massachusetts Committee on Mental Disease; Dr. Vincent Y. Bowditch, Boston, president of the Massachusetts Anti-Tuberculosis League, and Dr. Richard M. Smith, Boston, member of the Child Conservation Committee of the state department of health. Funds have been made available to meet all expenses of the work, which began in July. Dr. Edward Reynolds is chairman of the board of directors. The headquarters of the committee are at 525 Boylston Street, Boston.

MICHIGAN

Influenza Prophylaxis.—It was reported from Flint, October 26, that at the Michigan School for the Deaf, with 300 pupils and fifty employees, not a single case of influenza had developed on account of the fact, it is believed, that every person connected with the institution was required to wear a face mask following the order of the board of health, October 17. No other preventive measure was used.

MISSOURI

Personal.—Dr. Henry L. Wolfner, St. Louis, has been elected president of the St. Louis Board of Education.

Advocate Use of Serum.—The St. Louis Medical Society, October 23, appointed Dr. C. H. Smith, assistant health commissioner, Elsworth S. Smith, William Engelbach, George Ives, and Charles W. Schery, a committee to further the use of the new serum to prevent deaths from pneumonia in influenza cases.

Arrest of Physicians Ordered.—Orders are said to have been issued by the St. Joseph Board of Health, October 24, directing the city health officer, Dr. Hasbrouck De Lamater, to swear out a warrant for the arrest of Dr. Clayton F. Imus, charged with failing to report a case of influenza, and Dr. Reinhold Willman, charged with tearing a quarantine sign from a house without permission from the board of health.

State Board Election.—At the annual meeting of the state board of health, held October 16, Dr. William A. Clark, Jefferson City, was elected president; Dr. Andrew W. McAlester, Columbia, vice president, and Dr. George H. Jones, secretary (reelected).——The board decided that the precautionary measures instituted on account of the epidemic of influenza should be continued for an indefinite period.——The board has withdrawn its recognition of the St. Louis College of Physicians and Surgeons.

St. Joseph Physicians Form Unit.—Dr. William J. McGill, St. Joseph, has organized and will direct a Naval Station Unit, the personnel of which is composed of Lieut.-Com. William J. McGill, director; Lieut.-Com. Clarence A. Good, chief of the medical section; Lieut. L. Robert Forgrave, eye, ear, nose and throat specialist; Lieut. Julius S. Weingart, Des Moines, Iowa, specialist in laboratory and pathology. This unit will serve either on hospital ships or in base hospitals in this country or overseas. Additional assistants will be assigned if needed by the Surgeon-General, and nurses will be furnished by the American Red Cross.

NEW YORK

Diphtheria in Troy School.—There has been an outbreak of diphtheria among the 700 students of the Rensselaer Polytechnic Institute, who are enrolled in the Students' Army Training Corps. The Schick test is being applied to every student, and those who are found susceptible will be immunized.

New York City

Personal.—Dr. Charles H. Chetwood, former head of the department of urology of the New York Polyclinic Hospital, has been appointed consulting surgeon to the French Hospital.

Government Takes City Hospital.—The federal government is about to take over North Brother Island from the city and will maintain the Riverside Hospital as a military institution. The Riverside Hospital has accommodations for 1,000 patients.

Society Rejects Council Report.—Members of the Kings County Medical Society at a meeting, held October 15, are reported to have refused to accept a recommendation of the council of the society that the investigation of Dr. James P. Warbasse be dropped, and to have voted to accept a report that the charges against the physician were well founded.

National Committee for the Prevention of Blindness.—This organization will hold its annual meeting, November 26, at 8:30 p. m., at the New York Academy of Medicine, New York City. The chief speaker of the occasion will be Lieut.-Col. James Bordley, M. C., U. S. Army, Baltimore, whose subject will be "The Government and Red Cross Work for Blinded Soldiers."

OHIO

Smallpox.—At Elyria, October 26, there were nineteen houses under quarantine on account of smallpox, and the total number of cases in the city was twenty-six.

Illegal Traffickers in Drugs Punished.—October 23, Drs. George S. Iddings, T. A. Harris, Horace C. Bliss, and Miss Sarah Wilkins, a nurse, all of Cleveland, were charged with unlawful traffic in morphin and other drugs. Dr. Iddings is said to have pleaded guilty and sentenced to pay a fine of $500 and to thirty days imprisonment in jail; in the case of Dr. Harris a fine of $100 and costs and imprisonment for thirty days was held in abeyance pending a hearing of a *motion in mitigation*; a fine of $50 and costs in the case of Miss Wilkins was suspended; and in the case of Dr. Bliss, who pleaded not guilty, the case was continued until November 12.

Personal.—Dr. Adam W. Montague, receiving physician at the Cincinnati General Hospital, has resigned.——Dr. Ira H. Hawes, Arcanum, sustained serious injuries by the overturning of his automobile near Ithaca, October 20.——Dr. Daniel Heimlich, Cleveland, is ill with pneumonia at Mt. Sinai Hospital.——Dr. Foster D. Keiser, Tippecanoe City, is reported to be ill with pneumonia, following influenza, at the home of his brother in Piqua.——Dr. William C. Coultrap, Columbus, is reported to be critically ill with influenza at Mt. Carmel Hospital.——Dr. Roscoe R. Kahle has been appointed by the board of administration consulting surgeon to fill in for major surgery in any of the state institutions.——Dr. Oscar M. Craven, District Physician for the Cincinnati Health Department, has been appointed assistant health officer.——Dr. Carrie A. Richeson, Bellefontaine, has been elected secretary of the Logan County Medical Society to fill the unexpired term of Dr. Guy J. Kent, deceased.

PENNSYLVANIA

Personal.—Dr. Frank C. S. Blessing, Pittsburgh, is reported to be ill with pneumonia.——Dr. Edwin S. Dorworth, Bellefonte, is reported to be critically ill as the result of a cerebral hemorrhage.

Influenza Hospitals Opened.—The Mid-Valley Emergency Hospital, Olyphant, was opened to receive patients, October 17. Dr. Frederick L. Van Sickle, Olyphant, is in charge of the institution.——An emergency hospital for Conshohocken was opened in the Conshohocken Baptist Church, October 14, with Dr. George N. Highley in charge.

Philadelphia

Personal.—Dr. Harry Lowenburg has recovered from his recent illness and has resumed practice.——Dr. Edward Martin has resigned as John Rhea Barton professor of surgery in the University of Pennsylvania, and Dr. John B. Deaver has been elected his successor.——Dr. Allen J. Smith has been elected dean of the Medical School of the University of Pennsylvania.

Good Work in Influenza Epidemic.—The College Hospital of the Woman's Medical College has just closed its emergency hospital, established in cooperation with the Sun Shipbuilding Company during the influenza epidemic. The hospital was located on the river front just behind the transport docks.——The three upper college classes were mobilized for hospital service in the first days of the epidemic, and it was therefore possible to run the main college hospital to its full capacity with special wards equipped in the gymnasium, together with the emergency hospital in the poorest quarters of the city. Senior students were also sent as aids to physicians in the more severely stricken parts of Philadelphia. Hospital aids trained in the wards of the hospital during the previous winter together with other volunteers gave needed relief to regular nurses and evening auto trips provided by the Red Cross of Cynwyd reduced the morbidity and mortality among the nursing staff to a minimum. Two women ambulance drivers maintained the service night and day throughout the epidemic.

Cooperation of Medical Students in the Epidemic of Influenza in Philadelphia.—At the height of the influenza epidemic, October 2, at the request of Major Griffith, military commandant at the University of Pennsylvania, Dr. H. C. Wood, Jr., professor of pharmacology and therapeutics, organized an influenza emergency hospital, at first to take care of the students in the university who became ill and who could not be admitted to other hospitals on account of their crowded condition. The hospital was opened in a fraternity house which was being prepared as a barracks for the Student Army Training Corps. This hospital was made ready within twenty-four hours and was soon filled, on account of the rapid increase in the number of cases at the university and throughout the city. October 6, a call was issued for all third and fourth year medical students to report to the hospital where they were organized for service, not only in the university, but throughout the city. From these classes seventy-two men were supplied to the Red Cross Hospital, thirty-eight at various other city hospitals doing emergency work, and nine at other hospitals in the immediate vicinity of the university. This was in addition to those employed on the campus. In all, nineteen hospitals were supplied, either in whole or in part, with residents and interns from the members of the two classes. Many of the students visited private patients under the auspices of the city board of health, University Settlement, and some other organizations. These men were employed not only as interns, but also as nurses and orderlies and did other necessary work in caring for the influenza patients during the emergency, working long hours and showing the greatest spirit of self sacrifice. A number of them became ill in the performance of their voluntary duties.

WASHINGTON

Medical Society Facing Charges.—The Washington Hospital Association has requested that the King County Medical Society be permanently enjoined from further alleged acts, and also asked that a mandatory injunction be issued compelling the association to restore to full membership Drs. J. C. Moore, Frederick A. Cook, R. P. McClain and W. E. McClain, who were suspended last summer for having, it is alleged, served the association. The association charges the members of the King County Medical Society are being coerced to withdraw and keep their services from the association.

Personal.—Dr. Alice M. Smith, Tacoma, has been elected a fellow of the North British Academy of Arts, and an honorary member of the council.——Dr. Alexander R. Lundgren, Spokane, is reported to be seriously ill at his home with pneumonia.——Dr. Edward P. M. Condon, Spokane, is ill at the Sacred Heart Hospital with pneumonia following influenza.——Dr. William W. Webb is reported to be seriously ill with influenza.——Dr. Miles U. Lieser, Vancouver, who has been critically ill with influenza, is reported to be improved. ——Dr. Ida N. McIntire is said to be seriously ill at her home in Everett.

CANADA

Memorial Tablet.—The Regina (Sask.) Medical Association will erect a tablet in the local General Hospital to the memory of Dr. E. E. Meek, Regina, who was killed in France while operating on a wounded soldier in a Red Cross Hospital bombed by German airmen.

Must Be Military Surgeons Only.—It is reported from Ottawa that the Federal military authorities will require that all military physicians in Canada who are on the pay roll, will in future be required to devote their whole time to their military duties and discontinue their private practices. The order issued reads as follows: "No medical officer who is engaged in civil practice will be permitted to draw full time pay and allowance except when sent for temporary duty away from his home station."

Personal.—Lieut.-Col. Charles S. McVicar, Toronto, who returned from overseas recently where he was on the Orpington Hospital staff, has been appointed senior physician at the Spaldina Military Hospital, Toronto.——Dr. Roy H. Thomas, who has been overseas between two and three years, has been awarded the Military Cross.——Capt. J. H. Box, Lieut. Hendry Connell, Kingston, Ont., and Major Wellington M. Carrick, M.D., Hamilton, Ont., have gone as medical officers with the Canadian Siberian Expedition.

Tablet to Soldier Poet.—A memorial tablet has been placed in the Royal Victoria Hospital, Montreal, in honor of Col. John McCrae. It contains the following inscription: "In memory of Lieut.-Col. John McCrae, assistant pathologist and assistant physician, 1904-1917, chief of the medical division No. 3, McGill Canadian General Hospital, Boulogne, France, consultant of the First Army. Died on active service in France, Jan. 28, 1918." Then follow the stanzas of Colonel McCrae's famous poem, "In Flanders Fields."

GENERAL

Unauthorized Solicitor Appointing Medical Examiners.—We are informed that an individual signing himself "W. W. Beck" is appointing physicians as medical examiners of the Colonial Guards of America, soliciting a fee of $5. When last heard from he was working in Ohio. Mr. F. L. Runyon, secretary of the Colonial Guards of America, states that Mr. Beck is not authorized to solicit for the organization.

Missouri Valley Physicians Elect New Officers.—At the thirty-first annual meeting of the Medical Society of the Missouri Valley, held in Omaha, September 19 and 20, Des Moines was selected as the next place of meeting, and the following officers were elected: president, Dr. Charles Wood Fassett, Kansas City, Mo.; vice presidents, Dr. Elbert J. Watson, Diagonal, Iowa, and Dr. Joseph M. Aikin, Omaha; secretary, Dr. S. Grover Burnett, Kansas City, Mo., and treasurer, Dr. Oliver C. Gebhart, St. Joseph.

Bequests and Donations.—The following bequests and donations have recently been announced:

The City of Duquoin, Ill., $200,000 for a hospital for the city by the will of Mrs. Lillie A. Browning, Chicago.

Federation of Jewish Charities, Philadelphia, 4 per cent. of the income from the real estate of the late Samuel Sternberger, not to exceed $1,000 annually; Jewish Hospital Association 2 per cent. of the income from the same source not to exceed $500 annually. Also a payment of $20,000 to the Federation of Jewish Charities, and $10,000 to the Jewish Hospital Association, only the interest from these funds to be used.

Federation of Jewish Charities, Philadelphia, a bequest of $2,500 by the will of Eva K. Coons.

Influenza.—The influenza epidemic seems to be subsiding generally throughout the country and places heretofore closed have been opened gradually. November 2, the new cases of influenza reported from the Army camps for the previous twenty-four hours was 1,577 against 2,076 for the twenty-four hour period preceding that. The new pneumonia cases were 292, an increase of 12. The deaths for November 2, were 103, equalling the total for the previous day, but making a low record for influenza. October 30, according to the report of the emergency public health committee, approximately 11,000 deaths from influenza had occurred in Massachusetts, but it has now almost subsided. October 11, it was reported from Cape Town that influenza was spreading with alarming rapidity throughout South Africa.

Allied Surgeons Tour America.—A party of eminent surgeons from abroad has been making a tour of the United States acompanied by Lieut.-Col. George E. Brewer, M. C., U. S. Army, New York City; Col. William J. Mayo, M. C., U. S. Army, Rochester, Minn.; Col. Franklin H. Martin, M. C., U. S. Army, Chicago, and Dr. Pilcher, New York City. They have been entertained and have delivered addresses on various phases of military surgery in St. Paul, Rochester, Philadelphia, Chicago, New York, and other cities. The party consists of Col. Sir Thomas Myles, Dublin, Ireland, Major G. Gray Turner, New Castle-on-Tyne, England, Col. George E. Gask, St. Bartholomew's Hospital, London, Prof. Raffaele Bastianelli and Major Pouletti, Rome, Major Pierre Duval and Lieut. Henri Beclere, Paris, and Major Poillet, Ambre, France.

FOREIGN

War Fund for Physicians.—The *Nederlandsch Tijdschrift* quotes a German exchange to the effect that the Leipzig League is appealing urgently for contributions to its war fund to aid physicians, saying that the monthly appropriations from it are already 5,000 marks, and the demand is increasing week by week. Funds are needed also for aid to physicians' families, especially for widows of physicians.

Increased Legal Rates for Medical Services in Prussia.—According to the *Nederlandsch Tijdschrift*, the Prussian minister of the interior has ordered that the minimum payment for medical services by the state, insurance companies, charitable institutions, etc., is to be raised by 50 per cent. after September 1. This increased rate is to prevail for a year after the war. The maximal remuneration for specialist work is also increased. By mutual agreement the maximum rates can be surpassed, but in case of dispute the legal tariff is a guide to the courts.

Death of British Naval Officer.—Surg. John Hadwen, lieutenant-commander, Royal Navy, senior surgeon on *H. M. S. Lancaster*, in service on the Pacific Station, died at the Agnew Sanatorium, California, October 23, from pneumonia following influenza. Dr. Hadwen was 35 years of age; M.B., B.S., M.R.C.S., L.R.C.P. (Lond.), 1907. An international funeral service was held, October 24, participated in by Rear Admiral William Fullam, U. S. Navy, with his staff, and Admiral B. H. Holcomb, Royal Navy, with his staff and companies of sailors from the *U. S. S. Oregon* and *H. M. S. Lancaster*.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Standardization of Antiserums in Uruguay.—The *Revista Medica del Uruguay* states that the Consejo Nacional de Higiene has now made definite arrangements for the control of the production and sale of therapeutic serums made in Uruguay, and of conditions to regulate their sale in other countries.

Student Congress.—The *Revista Medica del Uruguay* relates that arrangements are under way for a general gathering of the students of the universities of the countries which owe their liberty to Bolivar, namely, Ecuador, Bolivia, Peru, Colombia and Venezuela. The University of Guayaquil has taken the lead in the matter.

Radium Loaned by Uruguay to Brazil.—Dr. C. Butler, director of the Radiology Institute of Montevideo, was sent recently to Rio de Janeiro with the amount of radium which the Facultad de Medicina of Montevideo was empowered by the government to loan to the Facultad de Medicina of Rio de Janeiro. The university authorities invited him to deliver an address on the results achieved with radium in Uruguay, and he described with lantern slides the work done at the institute in his charge.

CORRECTION

Marriage Notice Incorrect.—THE JOURNAL for October 19 contains announcement of the marriage of Lieut. Maurice Rashbaum to Miss Justine Todd. The announcement was based on a letter received by THE JOURNAL, signed L. Todd. We are requested both by Miss Todd and by Lieutenant Rashbaum to state that the announcement was incorrect.

BUENOS AIRES LETTER

Buenos Aires, Sept. 13, 1918.

University Interchange

Since last year there has been established an active interchange of professors between the medical departments of the universities of Buenos Aires, Rio de Janeiro and Montevideo. During the current year Dr. Etchepare, professor of psychiatry at Montevideo, and Dr. Austregesilo, professor of clinical neurology at Rio de Janeiro, have delivered lectures in Buenos Aires. The latter is still in the city. One of his lectures was on "Vagotony," one on "Studies of the Reflexes" and one is announced on "Cataphrenias."

On the occasion of the second South American Conference on Hygiene, Microbiology and Pathology, which is to convene at Rio de Janeiro, October 15, at the same time as the eighth Brazilian Medical Congress, several Argentine professors are to go to Rio, among others Drs. Araoz Alfaro, Zarate, etc. The national government has sent various delegates.

The local Facultad de medicina has arranged with the facultad of the University of Montevideo for an annual interchange of some of the professors.

Changes in the Medical Staff of the University

When the time came for election of the dean of the Facultad de medicina of Buenos Aires, the minister of public instruction requested that the election should be postponed until after the approbation of the reform of the statutes of government of the universities which had been submitted for government approval and action. This request for delay was badly received by some of the professors, and they sent in their resignation. As the dean, Dr. Bazterrica, had completed his term and no one had been appointed to succeed him, the oldest member of the staff, Dr. Eliseo Canton, was called to the direction of the school.

Infant Mortality

In view of the increase in infant mortality in the last few years, the Sociedad de Pediatria is to devote some special meetings to the study of this medico-social problem. They have invited other medical associations of the country and of Uruguay to take part in the conferences.

The Sociedad Eugenica Argentina has just been founded.

MADRID LETTER

Madrid, Oct. 1, 1918.

Epidemic Influenza Swoops Down on Spain Anew

After the subsidence of the epidemic of influenza in Spain last spring, the summer was extremely dry, the drought being worse than even the oldest inhabitant could remember, and the epidemic of several months before flared up again, and this time in a severer form. It seems that the Pfeiffer bacillus alone or associated with the pneumococcus and streptococcus is producing in certain localities a form of influenza that is fatal in a few hours. As I am writing there are some towns in which every inhabitant has been stricken, and others in which of the total of 500 inhabitants, only seventy or eighty are still on their feet. All the others are sweating and shivering in their beds, waiting for the visit from the doctor, always the true hero and today as ever the victim of a still imperfect sanitary organization. The disease at its first outbreak seemed to yield to the extreme hot weather, but in this second outbreak it has spread throughout the whole of Spain, this wide diffusion favored by official inefficiency and irresponsibility, which ought to be penalized. Nothing of the kind will be done, however, as politics and the dependent situation of the medical officers, subordinate to the civil authorities, impede the regular and systematic functioning of the public health service, which otherwise might have checked the advance of this second epidemic of grip. Notwithstanding the official decrees that the local authorities are to inform the central national authorities when there is a change in public health conditions in their respective regions, many, very many mayors, in order not to interrupt some local festival or shorten the stay of resorters, have kept silent in regard to the presence of the epidemic, threatening the local health officer that he is not independent and is not free to express his views on the arbitrary conduct of the local authorities, often heedless or ignorant of sanitary problems.

The Spring Epidemic of Influenza

Toward the close of last spring the whole of Spain was invaded by a disease sudden in its appearance, brief in its course, and subsiding without leaving a trace: general malaise, headache, pains in joints and muscles, high fever, slight bronchitis, much sweating and . . . after three days we were out again, a little weak and pale, and telling our friends how we had just had the . . . the . . . What should we call what we had been having? Some name had to be found, and the Madrilenians, as a joke, soon found a name for it. Not long before there had been a musical comedy at one of the theaters, "The Song of Forgetfulness," and one of its numbers, the "Soldier of Naples," sung by a patrol of soldiers, became very popular and was hummed, whistled and played until every one became deathly tired of it. As every one had become deathly tired of the disease we had been having, and as no one seemed able to escape from the tune or the disease, the latter was dubbed "the Naples soldier" too.

THE PANDEMIC OF INFLUENZA

When the epidemic in Spain subsided with the onset of the heated term, every one supposed that the calamity was over, and we were surprised to learn that the disease was making ravages in other countries, and that people there were calling it the "Spanish grip." And wherefore Spanish? Was it not the same grip that Chauffard had observed in Paris and had reported at a meeting of the Société médicale des hôpitaux several weeks before it had made its appearance in Spain? The germ may have increased its virulence and its power of diffusion in Spain, but it is evident that this epidemic was not born in Spain, and this should be recorded as a historic vindication. The extraordinary spread of epidemic influenza and its alarmingly rapid propagation are due to the fact that, as the bacilli are installed in the pharynx and as one of the characteristics of the disease in its incipience is a tickling in the throat, a slight pharyngotracheitis, there is a frequent impulse to cough and hawk, before the general health is impaired so that one has to stay in bed. This coughing relieves the tickling in the throat, but at the same time it spreads droplets of the secretions around and with them the dangerous bacilli, which are inhaled by healthy persons and multiply in them. Expectorated sputum, as also the expelled droplets, dry on the ground and the bacilli on them get breathed in dust. It is obvious that in offices, theaters, street cars, cafés, etc., the epidemic encounters the most favorable conditions for its diffusion.

From all over Europe news came to us that our guest, the famous "soldier," had been converted from "Neapolitan" into "Spanish," and we heard of the same diversities of opinion and judgments as we had in our own home. But now—we thought—we could be tranquil spectators, instead of actors, not knowing of the second representation of the comedy, which was even then preparing for us and which soon turned into a tragedy. This confirmed what Dr. Cortezo, the president of the Academia de Medicina and director of the *Siglo Medico* had said in regard to the menace of aggravation of the epidemic when it seemed on the point of disappearing, which had been a feature of other epidemics of influenza.

MORTALITY OF THE EPIDEMIC

A few days after the first cases we learned that some friend with heart disease had succumbed to the "soldier"; then we heard of others with chronic bronchitis, kidney disease or other taints, and in a week from the first case the death rate of the city had doubled. The physicians were exhausted, the druggists had to get extra help, and the city and state executive offices were closed, as also offices of all kinds, shops, schools and theaters. Even the famous "soldier song" was not heard any more. The laboratories collected material for research on the exact diagnosis and published varied and picturesque reports in the daily papers. According to some it was a tropical disease, others regarded it as the immediate effect of meteorologic conditions, some ascribed it to a certain species of mosquito while at that time none of those mosquitoes were to be found in Madrid; others attributed it to some insect prevalent in the Balkan states, and there were even some chemical authorities who attributed it to asphyxiating gases.

REPORT OF SCIENTIFIC SOCIETIES

The highest authority in medical matters in Spain, the Academia Nacional de Medicina, declared that it was the grip, the features of the epidemic being closely analogous to those of the pandemic of 1889 and 1890 which the majority of the members remembered. The association comprising younger men, the Academia Medico-Quirurgica, accepted the same diagnosis, and Dr. Falco presented specimens showing the Pfeiffer bacillus more distinctly than had been possible hitherto, and the findings were positive in nearly every case examined.

FALCO'S BACTERIOLOGIC TECHNIC

Falco follows Pfeiffer's original technic as modified by his pupil, Scheller. The main point is to rinse the sputum thoroughly and disintegrate it, first in saline and then on the slide. The bacillus is generally ensconced in the very center of the masses of sputum, and the mucin prevents the stain from reaching the bacillus. Hence the enormous difference between the findings of those who take pains in this direction and those who prepare the specimens with defectively disintegrated and washed sputum. Falco does not apply the Pfeiffer procedure with dilute fuchsin at once, but applies the Gram method first, and then the Pfeiffer dilute fuchsin technic.

For inoculation of agar he uses an emulsion of the sputum in sterile bouillon. Thanks to the predominance of the Pfeiffer bacillus over all others, this dilution favors pure cultures. Instead of inoculating the agar as Pfeiffer does and then adding a few drops of blood taken directly from the wing of a pigeon or the human finger, Falco first hemolyzes the blood, as the hemoglobin is the only element in the blood that is necessary for the proliferation of the Pfeiffer bacillus. Falco hemolyzes the blood and mixes it with the agar to begin with. He collects 10 or 12 drops of blood from a vein in the wing of a dove, drawing it directly into a test tube containing 15 or 20 c.c. of distilled water. He agitates the blood, which thereby becomes defibrinated and hemolyzed, and it is then mixed with 100 or 120 c.c. of agar, melted and cooled to 55 C., which is then poured rapidly over the plates.

LONDON LETTER

LONDON, Oct. 8, 1918.

The Prevention of Venereal Disease Among Soldiers

The prevention of venereal disease in the army and navy is a problem that has always exercised the authorities, and of course during this greatest of wars has received increased attention. Under the Defense of the Realm Act (an act giving the government special powers during the war), a regulation known as 40 D has been in force for some months. According to this regulation, "no woman who is suffering from venereal disease in a communicable form shall have sexual intercourse with any member of His Majesty's Forces or solicit or invite any member to have intercourse with her." The excellent intention of this regulation has proved most difficult to carry out. In only four out of the first eight cases in which charges arising out of it were made was a conviction obtained. Subsequently a lawyer acting for the police in a case said that in his experience prosecutions under the regulation had not turned out satisfactory; of five cases conducted by himself, all had failed. The difficulty was due to the time elapsing between the inception of the disease in the man and the examination of the woman. Commenting on this, the *Lancet* states that in a large proportion of cases it has proved impossible to establish the existence of "venereal disease in a communicable form," although some of the women were demonstrably leading a disorderly life. It adds that a searching bacteriologic examination involving the use of the vaginal speculum and the expression of secretion from the urethra and cervix may fail to establish evidence of infection in cases in which clinically it is almost certainly present. This is in harmony with the difficulty—according to some the impossibility—of curing gonorrhea in the female. Apart from the fact that the woman may be merely a carrier of infection without at any time clinically suffering, it may frequently happen that an infective spot is present in the genital tract beyond the reach of the most exhaustive examination. In other words, the coitus test is more delicate than the bacteriologic. Under the regulation, "a woman charged with an offense shall be remanded for the purpose of such medical examination as may be requisite for ascertaining whether she is suffering from such a disease"; but as no examination suffices to ascertain the presence of infection, the *Lancet* considers that this discredits the regulation as a public health measure. Furthermore, difficulty may arise as to positive medical evidence. Even when the woman is shown to be infectious, the length of time between inception of the disease and examination may leave the physician in doubt as to which party infected the other. The *Lancet* further considers that the examination of a woman not for the purpose of treatment and therefore not in her own interest, is a legal measure that does not commend itself to the moral sense of the majority of the profession.

The dangers to which soldiers are exposed by solicitation in the streets has been discussed in the *Times*. An American in this country, Mr. Bok, editor of the *Ladies' Home Journal*, wrote condemning very strongly the temptations to which American soldiers are exposed in the London streets and contrasting the conditions unfavorably with those in the neighborhood of the camps in America. He was answered, however, by another American editor, who said that the great American cities were in no way better than London. I may add that on personal inquiry at one of the American hospitals in London I have ascertained that the percentage of venereal disease among the patients is very small.

Pharmacy and the War

At the opening of the seventy-seventh session of the School of Pharmacy of the Pharmaceutical Society, Dr. Addison, the minister of reconstruction, delivered an address. He said that the greatest danger to much of our trade and industry had been German organization, training and method, especially in the application of physical science. Without being original themselves, the Germans took hold of the ideas of others, often British in their origin, and applied and developed them with painstaking thoroughness, so that in many British industries they had been gradually acquiring greater power than they would ever have gained by force of arms. The British nation needed a far more thorough and comprehensive application of science to industry and production in an organized form than they had hitherto sought to obtain. He spoke of the rude awakening in this country soon after we went to war because of our depending on Germany for many of the most commonly prescribed drugs and chemicals, and of the methods that had been successfully taken to cope with the difficulties arising from this cause. The result is that today there are none of those medicinal preparations of great importance that are not being made in amply sufficient quantities in this country. As examples he mentioned acetylsalicylic acid, salicylic acid and procain. Much progress has also been made in the home production of many wild plants, such as belladonna, so that the supply of many of these is fully adequate to our needs. The story of the combat with the deficient drug supply would provide a most interesting and attractive example of many of our national achievements during the war. The particular lesson standing out is that we must have a much better supply of trained chemists. When at the beginning of the war the British government advertised for trained chemists at a salary of $15 a week, this was a striking example of the kind of estimate the country at that time had formed as to the place of science in industry.

PARIS LETTER

PARIS, Oct. 3, 1918.

Did Grip of 1890 Confer Immunity?

The most extravagant stories have been circulating among the public with regard to the present epidemic of influenza, as though it were an entirely new disease. In reality it has long been known. As early as 1643, Etienne Pasquier described certain epidemics in which it is easy to recognize influenza. The Académie de médecine devoted to discussion of it nearly its entire meeting, October 1. Netter confirmed the absolute identity of the present epidemic with the one that raged in Paris in 1889-1890. In fact, the small number of cases occurring among old persons at this time may be taken to indicate that immunity to the disease was established by an attack dating back to the previous epidemic. This fact, of itself, would confirm the identity of the present disease. The course of the two epidemics is identical: Cases are benign at first, pulmonary complications later darkening the prognosis; there are intestinal complications, often with dysenteric characteristics; there is extreme contagiousness, to which physicians and nurses pay heavy tribute, and, finally, from the bacteriologic point of view, the bacillus of Pfeiffer is found in about half the cases. The progress of the epidemic cannot be followed from country to country, as was the case twenty-five years ago, this time, however, because of the military happenings. But there is no reason whatever for designating the disease "Spanish influenza or grip," when it is well known that it raged in Germany and in France before it occurred in Spain.

Drs. R. Wurtz and Fernand Bezançon have made an investigation of certain cases occurring in the hospitals of Paris, which by their unusual severity and the predominance of certain symptoms gave rise to the belief among the laity that the disease is cholera. This assumption is absolutely a wrong one. It is based entirely on the coexistence of the intestinal and pulmonary form of grip or of dysentery with cyanosis; but in every case, laboratory investigation has shown that there is not a single trace of any pestilence or exotic disease.

In the very severe cases, complicated by pulmonary edema, Dr. Ravaut advocates prompt bleeding, the withdrawal of from 500 to 700 gm. of blood, or even more, sometimes repeating the process. He also prescribes at the same time acetylsalicylic acid, if the kidneys are not affected, and hexamethylenamin when the urine is scanty and albuminous, the drug being administered orally or intravenously. Bleeding, in his opinion, is indicated in all cases of influenza of the congestive type accompanied by a frequent dry cough with beginning cyanosis.

The Food Supply

A very important step has just been taken to unify the means of provisioning the nation. A decree published in the *Journal officiel* provides that the minister of agriculture and food commissioner, who already is in charge of the provisioning of the armies in the field and of the civil population, shall also have charge of the provisioning of the ordinary troops and of the establishments of the Service de Santé. This will do away with the competition in the purchase of foods—which still exists—and finally unites the various services under one direction, unifying the various organizations that have hitherto had parallel functions in the distribution of food, placing on a common basis all goods, storehouses and personnel. The *magasins d'approvisionnement* of the Service de Santé, established in January, 1917, by M. Justin Godart, then undersecretary of state of the Service de Santé militaire, will cease to be the exclusive property of the military hospitals and of the Red Cross, but will be used, with all their resources, for general provisioning. They will be added to and merged with the regional *magasins* (storehouses) already established by the food commissioners in charge of the food supply for the civil population. This reform will make it possible to use the national resources to the best advantage, to fight the high cost of living, and, to a certain extent, it will help to lessen the difficulties of apportioning food between the various classes of consumers.

Exceptional Service Decorations for Medical Officers

M. Jean Ossola, deputy, has made his report in the name of the Commission de l'armée appointed to examine the proposition of M. Emile Constant, deputy from la Gironde, to admit to promotion in the Legion of Honor the officers of the Service de Santé who have rendered exceptional service. The report is favorable to M. Constant's proposition, and concludes thus: The Chamber of Deputies invites the government to include the officers of the Service de Santé among those military men who may be decorated by the Legion of Honor for exceptional services.

Legion of Honor for President of American Red Cross

The French government has bestowed the cross of commander of the Legion of Honor on M. Davidson, president of the American Red Cross, as an evidence of the high esteem in which he is held and in recognition of the great services that the American Red Cross has rendered to the war victims in France.

Death of Dr. Tribondeau

Dr. Tribondeau, *médecin principal de la marine*, died in the naval hospital at Achilleion, Corfu, aged 46. At first professor in the Ecole de Service de Santé de la marine, then head of the laboratory of bacteriology of the fifth arrondissement maritime, he was after several months called to direct the bacteriologic service of the Hôpital de l'Achilleion. Fatigued and already ill, he was on the point of returning to France when an epidemic of influenza made its appearance among the crews of the vessels stationed at Corfu. He insisted on remaining at his post to attend the sick, without thinking of himself. He was attacked by the disease and died in ten days.

Marriages

Lieut. Earl Hick Mitchell, M. C., U. S. Navy, Indianapolis, on duty at Tampa, Fla.; to Miss Mollie Melvine Tucker of Tampa, Fla., August 22.

Luther W. Little, Nemaha, Iowa, to Miss Selma V. Olsen, of Michigamme, Mich., at Des Moines, October 12.

Silas Addison Austin, to Mrs. Naomi N. Brown, both of Los Angeles, October 23.

Deaths

Walter Franklin Chappell ⊕ New York City; University of Toronto, Ont., 1879; M. R. C. S., England, 1881; aged 62; member of the American Laryngological Association, American Laryngological, Rhinological and Otological Society and American Otological Society; professor of clinical laryngology in the College of Physicians and Surgeons in the City of New York since 1910; surgeon to the Manhattan Eye, Ear and Throat Hospital, since 1887; consulting laryngologist to the Loomis Sanatorium; dropped dead in his office, October 19.

Major Frederick Oswin Waage, M. C., U. S. Army ⊕ Philadelphia; on duty at Fort Bliss, Texas; University of Pennsylvania, Philadelphia, 1904; aged 41; a member of the Association of Military Surgeons of the United States; formerly chief of the medical dispensary and chief anesthetist of the Methodist Hospital, Philadelphia; who entered the National Guard of Pennsylvania in 1907, and was on duty at the base hospital, Fort Bliss, Texas; died suddenly at that post, October 31, from heart disease.

Astley Cooper Clark, Pittsburgh; University of Pittsburgh, 1891; aged 48; a member of the Medical Society of the State of Pennsylvania; local surgeon to the Baltimore and Ohio System, and for twenty years surgeon for the Pennsylvania Railroad; a member of the surgical staff of St. Francis' Hospital for twelve years, and for three years president of the Lawrence School Board; died at his home, October 20, from pneumonia following influenza.

Jane Rogers Baker ⊕ West Chester, Pa.; Woman's Medical college of Pennsylvania, Philadelphia, 1892; aged 51; fellow of the American Medico-Psychological Association; who after serving in insane hospitals in Massachusetts, was given charge of the Insane Department of the Chester County Home in Embreeville, where she remained several years; originator of child welfare work in West Chester; died at her home, October 23, from typhoid fever.

John Ranly ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1891; aged 42; fellow of the American Academy of Ophthalmology and Oto-Laryngology; oculist and aurist to St. Francis, Good Samaritan and St. Mary's hospitals; instructor in the eye clinic of his alma mater; and recently made a member of the faculty; died at the home of his mother in Cincinnati, October 13, from pneumonia following influenza.

Robert B. Gray, Port Carbon, Pa.; Medico-Chirurgical College of Philadelphia, 1894; aged 52; a member of the Medical Society of the State of Pennsylvania; for six years, deputy coroner of the Port Carbon, New Philadelphia and Middleport district; for ten years a member of the Board of Health of Port Carbon and Palo Alto, and for one year a member of the Port Carbon council; died at his home, October 19.

George William Booher, Berry, Ky.; University of Louisville, Ky., 1917; aged 26; a member of the Kentucky State Medical Association; one of the first physicians of Harrison County to be commissioned in the Medical Reserve Corps, but discharged by reason of physical disability in September, 1918; died at his home, October 18, from pneumonia, following influenza.

Lieut. Glenn Dewey Ransom, M. C., U. S. Army ⊕ Big Rapids, Mich.; University of Michigan, Ann Arbor, 1913; aged 34; who was sent to England early in the summer of 1917, and later went to France with a hospital unit and was decorated by the French government in June, 1918, for bravery; died in France, last month, from wounds received in action.

Alexander Simpson Kelly ⊕ Oakland, Calif.; Cooper Medical College, San Francisco, 1901; aged 39; professor of operative surgery in Oakland College of Medicine and Surgery; for twelve years a member of the board of education, and for three years its president; died in the Oakland Central Hospital, October 24, from pneumonia, following influenza.

William Elmo Turton, Washington, D. C.; Georgetown University, Washington, D. C., 1908; aged 35; a member of the Medical Society of the District of Columbia; also a graduate in pharmacy; a medical employee of the Health Department of the District of Columbia; died at his home, October 10, from pneumonia following influenza.

Eugene Bryce Osborn, Cleburne, Texas; University of Texas, Galveston, 1896; aged 47; local surgeon of the Missouri, Kansas and Texas Railway, and chief surgeon of the

Dallas, Cleburne and Southwestern Railway; health officer of Cleburne and Johnson County; died at his home, October 19, from pneumonia, following influenza.

Lieut. Robert Kenton McGuffin, M. C., U. S. Army ⊕ Imperial, Calif.; Maryland Medical College, Baltimore, 1911; aged 33; a member of the Medical Society of the State of California; coroner of Imperial County; who was ordered to report for duty at Camp Kearney, October 23; died at his home, October 20, from pneumonia, following influenza.

William Benjamin Hardman ⊕ Commerce, Ga.; College of Physicians and Surgeons in the City of New York, 1889; aged 53; once president of the Medical Association of Georgia; president of the board of trustees of Mercer University, and president of the Bank of Commerce; died at his home, October 28, from pneumonia.

Manly J. D. Dantzler, Elloree, S. C.; Medical College of the State of South Carolina, 1861; aged 78; a member of the South Carolina Medical Association, and president of the Orangeburg County Medical Society; surgeon in the Confederate Service during the Civil War; died at his home, October 12.

Thomas Best Kramer, Washington, D. C.; Howard University, Washington, D. C., 1887; aged 66; a member of the Medical Society of the District of Columbia; also a graduate in pharmacy; and at one time pharmacist in the Navy; died at his home, October 11, from pneumonia following influenza.

William Hupp Sands ⊕ Fairmont, W. Va.; University of Pennsylvania, Philadelphia, 1898; aged 45; a specialist on diseases of the nose and throat; while driving in his automobile over a grade crossing near Fairmont, October 22, was struck by a Baltimore and Ohio train, and instantly killed.

Joseph James Wilson, Jr. ⊕ Coldwater, Miss.; Tulane University, New Orleans, 1907; aged 32; local surgeon of the Illinois Central Railroad; who received orders to report for duty at Camp Beauregard, La., the day of his death; died at his home, October 16, from pneumonia, following influenza.

David Webster Meyer, Brooklyn; Long Island College Hospital, Brooklyn, 1894; aged 47; surgeon to the Brooklyn Eye and Ear Hospital; consulting surgeon to Samaritan Hospital, Brooklyn; ophthalmologist to the Home for Consumptives; died at his home, October 24, from pneumonia.

Asst. Surg. Rushmer Christian Christiansen, Lieut., U. S. Navy ⊕ State University of Iowa, Iowa City, 1913; aged 28; who entered the Navy in July, 1917, and was on duty at Mare Island, Calif.; died in the Naval Hospital at Mare Island, October 19, from pneumonia following influenza.

Emanuel Joseph Leavitt, Brooklyn; College of Physicians and Surgeons in the City of New York, 1904; aged 41; radiologist to the Wyckoff Hospital, Brooklyn; a member of the staff of St. Mark's and the German hospitals; died at his home, October 24, from pneumonia, following influenza.

Selma Marstella Mason ⊕ Clarksburg, W. Va.; George Washington University, Washington, D. C., 1900; aged 41; chief surgeon of the Mason Hospital, Clarksburg; for several years coroner of Harrison County; died in the Mason Hospital, October 21, from pneumonia, following influenza.

Capt. Jean Paul Gay, M. C., U. S. Army ⊕ McAlester Okla.; University of Louisville, Ky., 1908; aged 34; in charge of the venereal disease campaign in Oklahoma, under the United States Public Health Service; died at his home, October 25, from pneumonia, following influenza.

Charles James Laffin ⊕ Gallup, N. M.; New York University, New York City, 1893; aged 51; who conducted a private hospital in New York City for many years and in 1908 entered the United States Indian Service; died at his home, October 18, from pneumonia following influenza.

Thomas Sanford Dunaway Grasty, Washington, D. C.; George Washington University, Washington, D. C., 1901; aged 38; a member of the Medical Society of the District of Columbia, and a specialist in pediatrics; died at his home, October 20, from pneumonia following influenza.

Flora Estella Parker Easton ⊕ Norristown, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1901; aged 46; for eight years a member of the staff of the Norristown State Hospital for the Insane; died in that institution, October 25, from pneumonia following influenza.

James Watt Keen, Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; aged 56; one of the first physicians of Philadelphia to report for emergency duty during the epidemic of influenza; died at the Emergency Hospital, Philadelphia, October 23, from influenza.

Lieut. Wendell James Phillips, M. C., U. S. Army ⊕ Corvallis, Ore.; Jefferson Medical College, 1915; aged 31; for two years physician in charge of the Oregon Agricultural College, Corvallis, Ore.; died at Camp Lee, Va., October 13, from pneumonia following influenza.

Thomas Howard Irwin, Moulton, Ala.; Vanderbilt University, Nashville, Tenn., 1900; aged 41; a member of the Medical Association of the State of Alabama; chairman of the Lawrence County Board of Health; died at his home, October 17, from pneumonia following influenza.

Frederick Allen Stafford, Phoenix, Ariz.; Hahnemann Medical College, Chicago, 1895; aged 28; a member of the Arizona Medical Association, and president of the Arizona Board of Medical Examiners; died at his home, October 18, from pneumonia following influenza.

Albert Johnson Terrell, Black Mountain, N. C.; University of North Carolina, Chapel Hill, 1908; aged 42; a member of the Medical Society of the State of North Carolina; died in the Meriwether Hospital, Asheville, N. C., October 13, from pneumonia following influenza.

George Wesley Gorrill ⊕ Buffalo; University of Buffalo, 1900; aged 41; American Medico-Psychological Association, and Buffalo Academy of Medicine; superintendent of the Buffalo State Hospital; died at his home, October 27, from pneumonia following influenza.

Clarence Sanford Faulkner ⊕ Elizabethtown, N. Y.; College of Physicians and Surgeons in the City of New York, 1913; aged 33; a member of the Board of Health of Elizabethtown and Lewis; died at his home, October 17, from pneumonia following influenza.

Lieut. Gerard Henry Lebret, M. C., U. S. Army ⊕ Montclair, N. J.; University of Maryland, Baltimore, 1913; aged 32; a member of the staff of Overbrook, the Essex County Hospital for the Insane; died at his home, October 17, from pneumonia following influenza.

Andrew Jackson Gray, Young America, Ind.; Medical College of Indiana, Indianapolis, 1897; aged 64; a member of the Indiana State Medical Association; for several terms a member of the board of commissioners of Cass County; died at his home, October 18.

William Tillman Burks, Fresno, Calif.; College of Physicians and Surgeons, San Francisco, 1900; aged 60; for some time president of the board of health of Fresno and health officer of Fresno County; also a druggist; died at his home, October 21, from pneumonia.

Charles L. Hough, Helena, Ark.; Jefferson Medical College, 1883; aged 57; also a druggist; died at his home in West Helena, October 15, from the effects of a gunshot wound of the head, self inflicted, it is believed, with suicidal intent, while despondent.

Jesse Robinson Kauffman ⊕ Blue Island, Ill.; Rush Medical College, 1907; aged 34; assistant professor of surgery in Loyola University, Chicago; local surgeon to the Rock Island System; died at his home, October 28, from pneumonia, following influenza.

William Henry Robinson, Eudora, Kan.; Kansas City, Mo., Medical College, 1872; aged 70; twice mayor of Eudora; and once postmaster of Liberty Mo., and Monticello, Kan.; died in the Swedish Hospital, Kansas City, Mo., October 18, from pneumonia.

Asst. Surg. Norwin Batte Norris, Lieut. (j. g.), U. S. Navy ⊕ Memphis, Tenn.; University of Tennessee, Nashville, 1917; aged 27; is reported in the *Official Bulletin* of October 14, as missing on the *U. S. S. Ticonderoga,* sunk, September 30, by a submarine.

Stanley Owen Sabel, New York City; College of Physicians and Surgeons in the City of New York, 1898; aged 42; visiting physician and a member of the medical board of Washington Heights Hospital; died suddenly at his home, October 20.

Joseph William Stone, Los Angeles; Jefferson Medical College, 1913; aged 32; a member of the Medical Society of the State of California; for several years a practitioner of Seattle; died at the home of his parents in that city, October 16.

Dean W. McKeen, Mena, Ark.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; St. Louis College of physicians and Surgeon, 1888; aged 65; died in the Christian Hospital, Kansas City, Mo., October 23, after a surgical operation.

John Cassel Buckwalter, Palo Alto, Calif.; Miami Medical College, Cincinnati, 1900; aged 45; formerly of St. Louis, associate professor of otology in the Marion-Sims Beaumont College of Medicine, St. Louis; died at his home, October 13.

John Kirk Formis, Lennox, S. D.; Northwestern University Medical School, Chicago, 1909; aged 38; who enlisted in the Medical Reserve Corps, U. S. Army, June 28, 1918; died at his home, September 30, from pneumonia, following influenza.

Edward Mosher Allen ⊕ Los Angeles; Rush Medical College, 1911; aged 33; assistant professor of obstetrics in the College of Physicians and Surgeons, Los Angeles; died at his home, October 21, from pneumonia, following influenza.

John George Mueller, Iowa City, Iowa; State University of Iowa, Iowa City, 1895; aged 47; for several years assistant in gynecology in his alma mater; died in a hospital in Iowa City, October 17, from pneumonia, following influenza.

Charles Elisha Collins, Rensselaer, N. Y.; Albany (N. Y.) Medical College, 1906; at one time a member of the Medical Society of the State of New York; for several terms city physician; died at his home, October 14, from heart disease.

Frank Hewitt Bartlett ⊕ New York City and Yonkers, N. Y.; College of Physicians and Surgeons in the City of New York, 1888; aged 62; a specialist in diseases of the ear, nose and throat; died at his home in Yonkers, September 14.

Francis Augustus Lane ⊕ Lynn, Mass.; Harvard Medical School, 1892; aged 50; formerly a member of the board of health of Lynn; for four years quarantine officer of the port of Boston; died at his home, October 29, from pneumonia.

Joseph Frank Etzbach, Chicago; State University of Iowa, Iowa City, 1905; aged 34; at one time a member of the Illinois State Medical Society; died in the La Salle (Ill.) Hospital, October 20, from pneumonia, following influenza.

Lieut. Guy Chaille Haralson, M. C., U. S. Army ⊕ Vicksburg, Miss.; Loyola University, Chicago, 1917; aged 36; assistant physician at the East Mississippi Insane Asylum; died at Fort McPherson, Ga., October 24, from pneumonia.

Phillips Carey Vaughan, Chicago; Rush Medical College, 1888; Bellevue Hospital Medical College, 1889; aged 51; medical director of the Ideal Sick Benefit and Accident Association; died at his home, October 25, from pneumonia.

Richard H. Schneider, Chicago; National Medical University, Chicago, 1907; aged 57; was found dead in his apartment, November 1; death being due, it is believed, to suicide by gas asphyxiation, while suffering from melancholia.

Died in the Service
IN FRANCE
LIEUT. WILLIAM C. KANTNER, JR., M. C., U. S. ARMY, 1885-1918
(See The Journal, last week, p. 1507)

Theophilus Radcliffe VanKirk, McKeesport, Pa.; Jefferson Medical College, 1864; aged 78; assistant surgeon of the Two Hundred and Ninth Pennsylvania Volunteer Infantry during the Civil War; died at his home, October 26.

Emil Henry Zimmerman, Colome, S. D., formerly of Cicero, Ill.; Loyola University, Chicago, 1913; aged 33; a member of the Illinois State Medical Society; died at his home, October 21, from pneumonia, following influenza.

Arthur Nolte ⊕ New Orleans; University of Virginia, Charlottesville, 1880; College of Physicians and Surgeons in the City of New York, 1881; aged 58; died at his home, October 24, from pneumonia, following influenza.

Lieut. Holman Simpson Siff, M. C., U. S. Army ⊕ Brooklyn; University and Bellevue Hospital Medical College, 1918; aged 24; an intern in Bellevue Hospital; died at his home, October 20, from pneumonia following influenza.

Thomas Eusebius Byrnes, Chicago; Loyola University, Chicago, 1918; aged 27; a member of the house staff of St. Bernard's Hospital, Chicago; died in that institution, October 10, from endocarditis following influenza.

William N. DeArmond, Fort Collins, Colo.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; aged 55; a member of the Colorado State Medical Society; died at his home, October 23, from influenza.

Frederick Waterman Cowles, West Brookfield, Mass.; Dartmouth Medical School, Hanover, 1892; aged 52; a member of the Massachusetts Medical Society; died at his home, about October 15, from bronchopneumonia.

William Williamson ⊕ San Diego, Calif.; McGill University, Montreal, 1891; a specialist on diseases of the eye, ear, nose and throat; oculist to the Sante Fe System; died in Los Angeles, October 19, from pneumonia.

A. Douglas Erwin, Fidelity, Ill.; Missouri Medical College, St. Louis, 1883; while returning from a hunting trip, October 7, was shot and killed by the accidental discharge of a gun carried by one of his companions.

Frank H. Weidemann, Connellsville, Pa.; Medico-Chirurgical College of Philadelphia, 1911; aged 40; local medical examiner for the Baltimore and Ohio System; died at his home, October 24, from influenza.

Wilmer Everett Toney, Red Stone, Mont.; University of Michigan, Ann Arbor, 1911; aged 34; for two years surgeon at the Northern Pacific Railway Hospital, Missoula; died at his home, October 18, from influenza.

Warren DeWitt Ratliff, Lucedale, Miss.; Tulane University, New Orleans, 1893; aged 52; member of the Mississippi State Medical Association; died at his home, about October 24, from pneumonia, following influenza.

Charles S. Wilkirson, Roff, Okla.; Chattanooga (Tenn.) Medical College, 1899; aged 40; a member of the Oklahoma State Medical Association; died in Sherman, Texas, October 16, from pneumonia following influenza.

Lieut. Joseph Daniel Rosenthal, M. C., U. S. Army ⊕ Brooklyn; New York Homeopathic Medical College, 1915; aged 27; died in the base hospital of Markleton, Pa., October 22, from pneumonia following influenza.

Lieut. Timothy Joseph Moran, M. C., U. S. Army ⊕ Pittsburgh; University of Pennsylvania, Philadelphia, 1905; aged 37; a specialist in ophthalmology; died in Camp Greenleaf, Fort Oglethorpe, Ga., October 17.

James H. Reynolds, Louisa, Ky. (license, West Virginia, 1896); aged 48; a specialist in diseases of the eye, ear, nose and throat; and also a druggist; died at his home, October 9, from pneumonia following influenza.

George J. Koch ⊕ Paterson, N. J.; College of Physicians and Surgeons, Baltimore, 1905; aged 38; a member of the staff of St. Joseph's Hospital, Paterson; died at his home in that city, October 19, from influenza.

Joseph White Humphrey Porter † Caribou, Me.; University of Pennsylvania, Philadelphia, 1901; aged 40; a specialist on diseases of the eye, ear, nose and throat; died at his home, about October 31, from pneumonia.

Lee G. Betts, Prairie City, Ill.; Ensworth Medical College, St. Joseph, Mo., 1902; aged 41; a member of the Illinois State Medical Society; died at his home, October 21, from pneumonia, following influenza.

Walter John McGibbon, Chateaugay, N. Y.; Montreal School of Medicine and Surgery, 1911; McGill University, Montreal, 1913; aged 32; died at his home, October 18, from pneumonia, following influenza.

William D. Krebs, Green Bay, Wis.; Marquette University, Milwaukee, 1914; aged 31; a member of the State Medical Society of Wisconsin; died at his home, October 18, from pneumonia, following influenza.

Henry Stark, Baltimore; University of Heidelberg, Germany, 1866; aged 74; for fourteen years city vaccine physician of Baltimore; died at his home in South Baltimore, October 23, from cerebral hemorrhage.

Joseph William Walsh, Portland, Conn.; College of Physicians and Surgeons, Baltimore, 1907; aged 33; a member of the Connecticut State Medical Society; died at his home, October 20, from pneumonia.

Lieut. Homer E. Van Epps, M. C., U. S. Army † [illegible] Ill.; Hahnemann Medical College, Chicago, 1916; aged [illegible] died recently at Camp Mills, Long Island, N. Y., from pneumonia following influenza.

William Nelson Carter, Columbus, Ga.; University of Louisville, Ky., 1906; aged 36; a member of the Medical Association of Georgia; died in the Columbus Hospital, October 17, from influenza.

George Willard Lent, Oxford, Pa.; Jefferson Medical College, 1891; aged 57; superintendent of the Oakwood Sanatorium, Oxford; died at his home, October 18, from pneumonia, following influenza.

Francis Melville Deems, Flushing, N. Y.; Bellevue Hospital Medical College, 1868; aged 72; associate physician to the Flushing Hospital; died at the Presbyterian Hospital, New York City, October 27.

William James McKnight, Brookville, Pa.; Jefferson Medical College, 1884; aged 82; also a druggist; a practitioner since 1857; state senator in 1880; a local historian; died at his home, October 12.

Edward Isadore Schwartz, Fresno, Calif.; College of Physicians and Surgeons, Los Angeles, 1918; aged 26; an intern in the Fresno County Hospital; died in that institution, October 21, from influenza.

Lieut. Robert Archie Sherwood, M. C., U. S. Army ⊕ University of Oregon, Portland, 1916; Army Medical School, Washington, D. C., 1918; aged 28; is reported to have died in action in France, September 17.

Died in the Service
in France
Lieut. Robert A. Sherwood, M. C., U. S. Army, 1890-1918

Lieut. Carl Bibb Hudson, M. C., U. S. Army ⊕ Montgomery, Ala.; Harvard Medical School, 1917; aged 30; died, October 2, a few days after his arrival in France, from pneumonia following influenza.

William P. Harvey, San Francisco; University of California, San Francisco, 1900; aged 43; a member of the Medical Society of the State of California; died at his home, October 27, from influenza.

J. Sanderson Lazarus, Bloomsburg, Pa.; Jefferson Medical College, 1868; aged 76; a member of the Medical Society of the State of Pennsylvania; died at his home, October 19, from heart disease.

Lewis Webster Burdick ⊕ Maryland, N. Y.; Albany (N. Y.) Medical College, 1909; aged 36; died in the Fox Memorial Hospital, Oneonta, N. Y., October 21, from pneumonia, following influenza.

Bradford Augustus Richards ⊕ Rochester N. Y.; McGill University, Montreal, 1901; aged 41; a specialist in diseases of the ear, nose and throat; died at his home, October 22, from pneumonia.

George W. Mullins, Milano, Texas; Kentucky School of Medicine, Louisville; at one time a member of the State Medical Association of Texas; died at his home, October 20, from pneumonia.

John Stanley Scott, Lake Charles, La.; Tulane University, New Orleans, 1912; aged 30; a member of the Louisiana State Medical Association; died at his home, October 17, from pneumonia.

Clinton Lee Hyatt, Kissimmee, Fla.; North Carolina Medical College, Charlotte, 1908; aged 37; a member of the Florida Medical Association; died at his home, October 17, from pneumonia.

Lieut. Chester Cameron Wood, P. A. Surg., U. S. Navy ⊕ on duty on *U. S. S. Alabama;* Jefferson Medical College, 1910; aged 30; who entered the Navy, May 4, 1915; died at sea, October 5.

Thomas B. Slaton, Greenville, Ky.; Barnes Medical College, St. Louis, 1902; aged 39; a member of the Kentucky State Medical Association; died at his home, October 20, from influenza.

Lieut. Edward Kenneth Lubin, M. C., U. S. Army ⊕ New York City; University and Bellevue Hospital Medical College, 1918; aged 24; died in Bellevue Hospital, October 27, from influenza.

Lieut. Ralph Waldo Turner, M. C., U. S. Army ⊕ Albany, N. Y.; Albany Medical College, 1917; aged 24; on duty at Fort Oglethorpe, Ga.; died at that post, October 17, from pneumonia.

True S. Burgess, Washington, D. C., formerly of Russellville, Ark.; George Washington University, Washington, D. C., 1912; aged 31; died at the home of his mother, October 22.

Walter Scott Muirhead, Floodwood, Minn.; University of Illinois, Chicago, 1909; aged 33; was burned to death, about October 13, in the forest fires which prevailed in northern Minnesota.

Foss Edwin Pratt, Ruston, Tacoma, Wash.; Cleveland College of Physicians and Surgeons, 1904; at one time mayor of Ruston; died in a hospital, in Tacoma, October 20, from pneumonia.

Lieut. Frank Benedict Rosinski, M. C., U. S. Army ⊕ Cleveland; aged 27; who had just been ordered to Fort Oglethorpe, Ga., for duty; died at his home, October 21, from influenza.

John Joseph O'Donnell, Boston; Harvard Medical School, 1915; aged 33; who had been in Los Angeles since January, died at that place in October from pneumonia following influenza.

William Meredith Gregory, Berea, Ohio; Cleveland Medical College, 1895; Cleveland College of Physicians and Surgeons, 1899; aged 61; died at his home, October 9, from influenza.

Lafayette Bennett, Elkton, Ky.; University of Tennessee, Nashville, 1900; aged 41; a member of the Kentucky State Medical Association; died at his home, October 20, from influenza.

Henry S. Lindley, Wilkinsburg, Pa.; Jefferson Medical College, 1866; aged 80; surgeon in the federal service during the Civil War; died at his home, October 10, from heart disease.

Charles Francis Montgomery ⊕ Roswell, N. M.; University of Missouri, Columbia, 1905; aged 39; died in St. Mary's Hospital, Roswell, about October 15, from influenza.

Horace David Hermany, Mohoney City, Pa.; Jefferson Medical College, 1892; aged 53; also a druggist; died at his home, October 21, from pneumonia following influenza.

Salamet Isa Aranki, Bridgeport, Conn.; College of Physicians and Surgeons, Baltimore, 1914; aged 32; a native of Jerusalem; died at his home, October 7, from influenza.

Lieut. Benjamin Franklin McArthur, M. C., U. S. Army ⊕ Lizelia, Miss.; Memphis (Tenn.) Hospital Medical College, 1905; aged 35; died at his home, October 20, from influenza.

Charles O. Zahner, Louisville, Ky.; University of Louisville, Ky., 1904; aged 38; professor of physiology in his alma mater; died at his home, October 11, from influenza.

Maude Leontine Morrison, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1917; aged 33; an intern in the Los Angeles County Hospital; died recently.

Wyatt Patrick Exum, Jr., Maxton, N. C.; Medical College of Virginia, Richmond, 1901; aged 43; died at his home, October 16, from pneumonia, following influenza.

Francis Graham Gardiner ⊕ Pittsburgh; University of Michigan, Ann Arbor, 1880; aged 68; died in the Passavant Hospital, Pittsburgh, October 22, from pneumonia.

George Davis Warren ⊕ Ozark, Ark.; University of Arkansas, Little Rock, 1911; aged 34; died at his home, October 19, from pneumonia following influenza.

Lieut. Herman Warner Krantz, M. C., U. S. Army ⊕ Union Bridge, Md.; University of Maryland, Baltimore, 1915; aged 27; died at his home, October 25, from influenza.

Harvey Marshall Vance ⊕ Pleasant Grove, Utah; University of Illinois, Chicago, 1903; aged 40; died at his home, October 16, from pneumonia following influenza.

William Augustus Keeley, Brooklyn; New York University, New York City, 1888; aged 51; died at his home, October 20, from pneumonia following influenza

Samuel Duffie Austin, Handsboro, Miss.; George Washington University, Washington, D. C., 1905; aged 42; died at his home, about October 25, from influenza.

Alfred Hincks Youngs ⊕ Pierre, S. D.; University of Minnesota, Minneapolis, 1907; aged 40; died at his home, October 16, from pneumonia, following influenza.

W. Lugene Seeger, Dallas, Texas; Baylor University, Dallas, 1913; aged 29; died at the Waxahachie (Texas) Sanitarium, about October 23, from pneumonia.

Clarence Wesley Batchelet ⊕ Pine River, Wis.; Milwaukee Medical College, 1912; aged 29; died at his home, October 21, from pneumonia, following influenza.

Alfred Friedman, New York City; College of Physicians and Surgeons in the City of New York, 1876; aged 67; died at his home, October 18, from pneumonia.

Kenneth Field Albee ⊕ Weston, Mass.; Harvard Medical School, 1914; aged 32; died at his home, September 23, from bronchial pneumonia following influenza.

Ralph Jiles Smirl, New Raymer, Colo.; Vanderbilt Medical College, 1915; aged 28; died in the Park Avenue Hospital, Denver, October 18, from influenza.

John C. McClenathan, Connellsville, Pa.; Jefferson Medical College, 1881; aged 66; formerly surgeon to the Cottage State Hospital; died at his home, October 26.

Andrew Donaldson, Kansas City, Mo.; University of Wooster, Cleveland, Ohio, 1874; aged 79; died at his home, October 5, from cerebral hemorrhage.

Stephen Finley Welton, Montezuma, Ga.; Meharry Medical College, Nashville, Tenn., 1909; aged 40; a colored practitioner; died at his home, October 7.

Merlin B. Wyatt ⊕ Manning, Iowa; University of Nebraska, Omaha, 1907; aged 35; roentgenologist; died at his home, October 22, from influenza.

Lorenzo R. Thornton, Filley, Neb. (License, Nebraska, 1891); aged 84; a veteran of the Civil War; died in the Soldiers' Home, Milford, October 17.

Giuseppe Vittorio Sbordone, New York City; University of Naples, Italy, 1889; aged 56; died at his home, October 21, from pneumonia following influenza.

Vincent Jastremski, Montegut, La.; Tulane University, New Orleans, 1897; aged 40; died at his home, October 19, from pneumonia, following influenza.

Curtis E. Bowers, Kersey, Colo.; Hahnemann Medical College, Chicago, 1902; aged 40; died at his home, October 22, from pneumonia following influenza.

Edward Charles Cekul ⊕ La Otto, Ind.; Indiana University, Indianapolis, 1914; aged 33; died at his home, October 24, from pneumonia, following influenza.

Kieran Joseph O'Neill, Coupeville, Wash.; University of Toronto, Ont., 1909; aged 30; died at his home, October 23, from pneumonia, following influenza.

Robert Lenard, Chicago; Illinois Medical College, Chicago, 1900; aged 44; died at South Chicago Hospital, October 27, from pneumonia, following influenza.

Francois DeSales Dube ⊕ Milwaukee; Milwaukee Medical College, 1908; aged 32; died at Amery, Wis., October 23, from pneumonia, following influenza.

Lawrence Dutcher Gillick, Pulaski, Wis.; Milwaukee Medical College, 1909; aged 32; died at his home, October 16, from pneumonia, following influenza.

Paul Henry Hesse, London Mills, Ill.; Chicago College of Medicine and Surgery, 1908; aged 45; died at the Red Cross Hospital, Kankakee, Ill., October 16.

Clyde Switzer Horton, Edgerton, Wis.; University of Illinois, Chicago, 1907; aged 38; died at his home, October 5, from pneumonia following influenza.

William G. Gardiner, Atlantic City, N. J.; Hahnemann Medical College, Philadelphia, 1888; aged 50; died at his home, October 17, from influenza.

Frederick Lovell Bogue ⊕ New York City and Mont Clair, N. J.; University of Pennsylvania, Philadelphia, 1895; aged 48; died at his home, October 26.

Lieut. Eugene Fellner Hull, M. C., U. S. Army ⊕ Berlin, N. Y.; Albany (N. Y.) Medical College, 1913; aged 30; died in Little Rock, Ark., October 18.

Charles J. Reimer, Jr. ⊕ Phoenixville, Pa.; Jefferson Medical College, 1911; aged 32; died at his home, October 13.

Edward John Miller, Urbana, Ill.; University of Illinois, Chicago, 1912; aged 30; died at his home, October 15, from pneumonia, following influenza.

Robert Henry Scott, Laingsburg, Mich.; Detroit College of Medicine and Surgery, 1894; aged 59; died at his home, October 15, from pneumonia.

Silas Baldwin Jacobs, Baltimore; Southern Homeopathic Medical College, Baltimore, 1905; aged 35; died at his home, October 17, from influenza.

Margaret E. Pomeroy, Salem, Ore.; Willamette University, Salem, 1904; died in Portland, Ore., October 23, from pneumonia, following influenza.

Joseph Emil Artiges ⊕ San Francisco; Cooper Medical College, San Francisco, 1887; aged 55; died at his home, October 22, from influenza.

Carl Logan Brown ⊕ Cawker City, Kan.; Kansas Medical College, Topeka, 1913; aged 33; died in Bennington, Kan., October 9, from influenza.

Lieut. Wilburn Edgar Hampton, M. C., U. S. Army ⊕ Ferris, Texas; University of Louisville, Ky., 1910; aged 31; died in Dallas, October 21.

Joseph A. S. Regli, San Jose, Calif.; Georgetown University, Washington, D. C., 1902; aged 42; died at his home, October 24, from influenza.

Alfred F. Skillman, McCracken, Kan.; Northwestern Medical College, St. Joseph, Mo., 1885; aged 61; died at his home, recently, from pneumonia.

John Marye Lewis ⊕ Manassas, Va.; University of Virginia, Charlottesville, 1905; aged 37; died at his home, October 14, from pneumonia.

George Ulrich Panzer, Truman, Minn.; Eclectic Medical Institute, Cincinnati, 1910; aged 37; died at his home, October 23, from influenza.

Ella Florence Preston, Dansville, N. Y.; Eclectic Medical College of the City of New York, 1882; aged 70; died at her home, October 15.

George Greer, Vandalia, Ill.; Missouri Medical College, St. Louis, 1882; aged 67; died at his home, October 17, from cerebral hemorrhage.

Edward Humble Moss, Cincinnati; Medical College of Ohio, Cincinnati, 1900; aged 43; died at his home, October 22, from pneumonia.

John H. Norman, Blanchester, Ohio; Eclectic Medical Institute, Cincinnati, 1875; aged 66; died at his home, October 22, from pneumonia.

Florence Josephine Chubb, San Francisco; University of California, San Francisco, 1918; died at her home, October 28, from influenza.

Paul Willis Brown ⊕ Springfield, Ohio; Barnes Medical College, St. Louis, 1899; aged 47; died at his home, October 14, from influenza.

Benjamin F. Beane, West Manchester, Ohio; Eclectic Medical Institute, Cincinnati, 1881; aged 67; died at his home, October 19.

William Jesse Bedell, New York City; Bellevue Hospital Medical College, 1898; aged 48; died at his home, October 23, from pneumonia.

John Eugene Goldstein, Brooklyn; Fordham University, New York City, 1916; aged 25; died at his home, October 18, from pneumonia.

John Henry Burkartmaier ⊕ Avondale, Pa.; Jefferson Medical College, 1911; aged 35; died at his home, October 18, from influenza.

Karl August Bieber ⊕ Tipton, Kan.; Kansas Medical College, Topeka, 1909; aged 34; died at his home, October 14, from influenza.

John J. Gambill, Martha, Ky.; Louisville (Ky.) Medical College, 1886; aged 75; died at his home, October 10, from heart disease.

Martin A. Montgomery ⊕ Owensville, Ind.; University of Louisville, Ky., 1898; aged 43; died at his home, about October 20.

Darvin S. Gailey ⊕ Ashland, Ill.; University of Illinois, Chicago, 1897; aged 42; died at his home, October 20, from septicemia.

Carl William Lutz, Ottawa, Ill.; University of Illinois, Chicago, 1915; aged 31; died at his home, October 19, from pneumonia.

Eugene Judy Primm ⊕ Chatham, Ill.; Barnes Medical College, St. Louis, 1910; aged 36; died, recently, from pneumonia.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MORE MISBRANDED NOSTRUMS

Baker's Tubercular Remedy.—Edward D. Morgan, who had been treasurer and general manager of the W. H. Baker Co. of Cleveland, Ohio, was charged with misbranding a product called "Dr. W. H. Baker's Tubercular Remedy." The stuff contained 11 per cent. alcohol by volume, sugars, potassium iodid, ammonium chlorid, glycerin, licorice, plant extractives, etc. The claim that the product was a remedy and cure for tuberculosis was declared false and fraudulent, and Morgan was fined $25 and costs.—[*Notice of Judgment No. 4998.*]

Lee's Save the Baby Croup Specific.—Charles Samuel Ulcher and Carrie L. Ulcher, who traded as Wm. W. Lee & Co., Troy, N. Y., were charged with misbranding this preparation. According to the government chemists, the product was a liniment with a fatty oil base, and containing camphor, rosemary and thyme. The claim that it was a specific for croup and for saving the lives of babies affected with that disease was declared false and fraudulent.

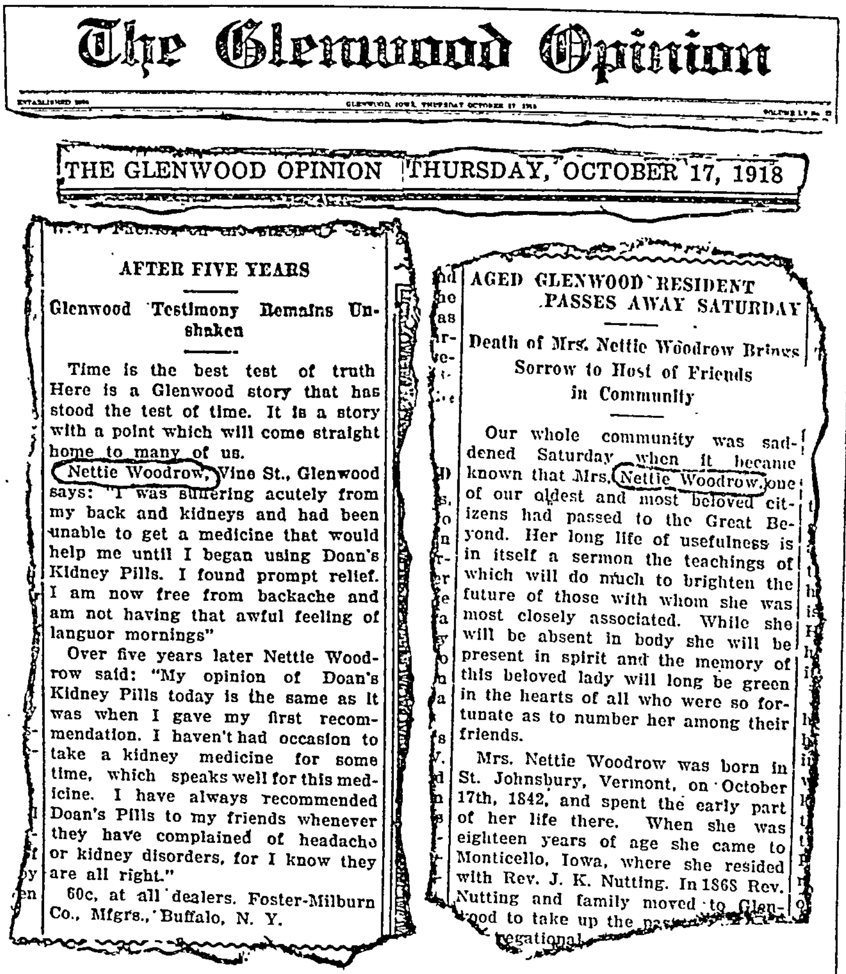
The same individuals were also charged with misbranding "Lee's Croup Mixture." which the government chemists reported contained over 70 per cent. of lard, about 7 per cent. alcohol, and more than 18 per cent. volatile oils, consisting of a mixture of oils of rosemary and thyme and camphor. This also was falsely and fraudulently represented to be a remedy for croup. The two Ulchers were fined $25.—[*Notice of Judgment No. 4999.*]

Twentieth Century.—This preparation was marketed by one Eva J. Powell of Findlay, Ohio, who traded under the name of the Twentieth Century Remedy Co. It consisted of a powder and a solution, the latter, according to the government chemists, being, essentially, a mixture of water, glycerin, lead and zinc sulphates, acetates, nitrates, and a small quantity of perfume. It was falsely and fraudulently represented to be a cure and preventive of gonorrhea and gleet. Eva J. Powell was convicted of misbranding and ordered to pay the costs of the proceedings.—[*Notice of Judgment No. 4982.*]

Moreau's Soothing Wine of Anise.—The Lafayette Co. of Berlin, N. H., shipped this product, which the government declared was being sold under false and fraudulent claims. The "soothing wine for children," according to the federal chemists, was a syrup containing morphin acetate and alcohol, and flavored with anise. It was falsely and fraudulently represented to be a remedy for diarrhea, dysentery, indigestion and vomiting of children. Furthermore, the package bore no statement regarding the quantity or proportion of morphin and alcohol. The company first pleaded not guilty, but later withdrew this plea and entered a plea of guilty; it was fined $25 and costs.—[*Notice of Judgment No. 4989.*]

Matthai's Victory.—Margarete E. Matthai of Baltimore, who did business as "Professor C. E. Matthai," sold a nostrum called, "Professor C. E. Matthai's Victory." The stuff contained 49 per cent. alcohol, 1.2 grains of opium to the fluidounce, and 3.5 per cent. camphor and volatile oil, and small amounts of red pepper. It was sold under claims that it was a remedy for diphtheria, cholera, rheumatism, scarlet fever, yellow fever, epilepsy, inflammation of the kidneys and bladder, diabetes and several other conditions. These claims the government declared were false and fraudulent. It was further misbranded in that the amounts of alcohol and opium declared on the label were less than the quantities actually present. The defendant was fined $100 and costs.—[*Notice of Judgment No. 4983.*]

MORE DOAN'S TESTIMONY FROM THE TOMBS



The Glenwood Opinion

THE GLENWOOD OPINION | THURSDAY, OCTOBER 17, 1918

AFTER FIVE YEARS

Glenwood Testimony Remains Unshaken

Time is the best test of truth Here is a Glenwood story that has stood the test of time. It is a story with a point which will come straight home to many of us.

Nettie Woodrow, Vine St., Glenwood says: "I was suffering acutely from my back and kidneys and had been unable to get a medicine that would help me until I began using Doan's Kidney Pills. I found prompt relief. I am now free from backache and am not having that awful feeling of languor mornings"

Over five years later Nettie Woodrow said: "My opinion of Doan's Kidney Pills today is the same as it was when I gave my first recommendation. I haven't had occasion to take a kidney medicine for some time, which speaks well for this medicine. I have always recommended Doan's Pills to my friends whenever they have complained of headache or kidney disorders, for I know they are all right."

AGED GLENWOOD RESIDENT PASSES AWAY SATURDAY

Death of Mrs. Nettie Woodrow Brings Sorrow to Host of Friends in Community

Our whole community was saddened Saturday when it became known that Mrs. Nettie Woodrow, one of our oldest and most beloved citizens had passed to the Great Beyond. Her long life of usefulness is in itself a sermon the teachings of which will do much to brighten the future of those with whom she was most closely associated. While she will be absent in body she will be present in spirit and the memory of this beloved lady will long be green in the hearts of all who were so fortunate as to number her among their friends.

Mrs. Nettie Woodrow was born in St. Johnsbury, Vermont, on October 17th, 1842, and spent the early part of her life there. When she was eighteen years of age she came to Monticello, Iowa, where she resided with Rev. J. K. Nutting. In 1868 Rev. Nutting and family moved to Glenwood to take up the pas
...gational

"Here is a Glenwood Story" says a Doan's Kidney Pills advertisement, "with a point which will come straight home to many of us." How true! The advertisement appeared in the Glenwood (Ia.) *Opinion* of Oct. 17, 1918, relative to Nettie Woodrow's use of Doan's Kidney Pills. On another page of the same issue was an obituary notice of Nettie Woodrow. As the Doan's advertisement sagely remarks: "Time is the best test of truth." The Journal has, at various times, published unfortunate coincidences similar to the one above. Doubtless it could publish more, did the Doan's concern not instruct newspapers which carry its advertising to return advertising "copy" containing testimonials of local people who have died!

Sensapersa.—This product was marketed by one Stephen Britton of New York City, who did business as the Brown Export Co. "Sensapersa," according to the government chemists, consisted of purple colored tablets containing asafetida, cannabis indica, and a drug containing a mydriatic alkaloid such as hyoscyamus. It was falsely and fraudulently represented to be a cure for "nervous trouble" and a remedy for neurasthenia, nervous prostration, nervous debility, etc. Britton was fined $50.—[*Notice of Judgment No. 4984.*]

When the valve lever is in line with the right hand tube, the sound enters the left ear, and vice versa. In other words, the sound is excluded from the side corresponding to the long axis of the lever. A midway position excludes from both ears. The valves work rather stiffly at first and the screw should be loosened and oiled if necessary. For voice tests the ordinary stethoscope bell may be used, or a small funnel may be substituted if the bell is too small.

For testing with tuning forks, the chest-piece with a hard rubber diaphragm has proved most satisfactory, and transmits the sound very well. Only the lower pitched forks (128 and 256) should be used, since it is difficult to exclude forks of higher pitch. If necessary to use these or the conversational voice, a long tube (6 or 8 feet) may be connected with the apparatus. At this distance the ear-pieces will prevent the entrance of the sound except through the channels desired. The three-way valves are very inexpensive and may be obtained from any supply house.

John Leshure, M.D., New York.

PROMOTION WITH LOSS OF INCOME

To the Editor:—In your information to prospective medical officers regarding pay, commutation of quarters for dependents, etc., there is one contingency, one throw of the dice, that may knock out these calculations.

I entered the service sixteen months ago. I am 45 years old and have a wife and five children. I was at San Francisco and Camp Fremont as a first lieutenant up to last month. Since April 15 I have been allowed commutation for my family in the state of Washington, which brought my check up to $203.28 a month.

I was sent to the Canal Zone and found on arrival I was a captain. I also found that there are quarters "to burn" at all the camps here. It will take between $400 and $500 to move my family down here any way I figure it, as they would have to come to New Orleans, 3,300 miles by railway, to meet a transport and probably have to wait a week or more in that city. The Pacific Mail charges $135 a ticket from San Francisco, and it would require three tickets, and there would be about $75 additional from Washington to San Francisco. I find myself in a big castle of a house all alone and a monthly check of $200 as a captain instead of my $203.28 as first lieutenant. No assurance can be had as to how long I shall be left here, so you can see that after we have all existed fourteen months on a lieutenant's pay I cannot take the chance of paying out so much money to transport my family here and possibly in a short time have to take them back. Besides, we own our home, which would probably stand idle.

So this proposition is a kind of a joke on me. But I am not kicking or complaining—only hoping the war will soon be over and that I can go home.

If you should find any reason for publishing any of this, please omit my name and city.

K. O. P.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DIRT AND CARBON REMOVER

For cleaning the hands after machine work and the skin locally for hypodermic medication, and for removing carbon from the cylinders of automobiles, I use a mixture of:

Denatured alcohol.
Volatile oil of turpentine (ordinary turpentine) of each......2 ounces
Ether .... 3 drams

Mix turpentine and alcohol, shake and add the ether.

From one half to one ounce is put in the cooled cylinders of the automobile and allowed to stand two or more hours. The mixture fires quickly and blows out the carbon with a good speed.

F. U. Ferguson, M.D., Gallitzin, Pa.

Iowa July Reciprocity Report

Dr. G. H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports that 7 candidates were licensed through reciprocity at the meeting held July 15, 1918. The following colleges were represented:

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Bennett Medical College		(1914)	Illinois
Northwestern University	(1905)	(1913)	Illinois
American Medical Missionary College		(1904)	Illinois
National University of Arts and Sciences		(1913)	Illinois
St. Louis College of Physicians and Surgeons		(1911)	Missouri
University of Nebraska		(1904)	Nebraska

Washington July Examination

Dr. C. N. Suttner, secretary of the Washington State Board of Medical Examiners, reports the written examination held at Tacoma, July 2, 1918. The examination covered 11 subjects and included 110 questions. An average of 75 per cent. was required to pass. Of the 38 candidates who took the physician's and surgeon's examination, 30, including 2 osteopaths, passed, and 8, including 2 chiropractors, failed. Ten candidates were granted osteopathic licenses. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Medical Evangelists		(1918)	94.3
College of Phys. and Surg., Los Angeles		(1918)	85, 87.5
College of Phys. and Surgs., San Francisco		(1918)	92.4
George Washington University		(1905)	89.2
Hahnemann Medical Coll. of the Pacific		(1914)	89.1

Book Notices

Radiography and Radio-Therapeutics. By Robert Knox, M.D., M.R.C.S., L.R.C.P., Consulting Radiologist, Great Northern Central Hospital, London. Part II: Radio-Therapeutics. Cloth. Price, $6.50. Pp. 606, with 115 illustrations. New York: The Macmillan Company, 1918.

This volume is devoted to both roentgen and radium therapy. The action of radiations on normal and pathologic tissues is dwelt on at some length. The roentgen armamentarium suitable for therapeutic use is described, as are also the methods of protection for patient and operator, the means used to estimate dosage, and the use of filters. Rather scant mention is made of the Coolidge tube—not at all commensurate with its importance and value in modern roentgen therapy. The chapters devoted to the various conditions suitable for treatment and the technic employed are also rather condensed. The physics of radium is dwelt on in detail by C. E. S. Phillips. The practical application of radium to disease, including the various methods of using it, the dosage and the conditions amenable to its action, is thoroughly covered. A chapter on the combined use of radium and roentgen rays in the treatment of malignant disease gives some relative values of the two agents in different conditions. The equipment of a radiotherapeutic department to meet the needs of military practice is described, as are also the types of cases encountered in such practice. In a chapter on the value of radiations in plastic surgery of the face and jaws, by Percival P. Cole, special attention is called to the value of the depilating effects of radiation when flaps from hairy parts are use to cover defects in nonhairy parts, and to the softening effects in old scars and keloids developing in such scars.

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Thomas Lewis, M.D., F.R.S., D.Sc., Physician of the Staff of the Medical Research Committee. Fourth edition. Cloth. Price, $2.25. Pp. 120, with illustrations. New York: Paul B. Hoeber, 1918.

This is essentially a reprint of the third edition, yet new facts are added here and there in a few words or a short paragraph, or some modification of statement is made so that it may justly be stated that there has been a careful revision. The worth of the volume has been many times declared by teachers and reviewers, and is plainly attested by the demand for the fourth edition. Not the least valuable feature is the preface, which clearly sets forth the debt owed by cardiology to the electrocardiograph and polygraph, but which also points out the fact that without these instruments of precision the general practitioner, by understanding the processes underlying cardiac irregularities, may recognize and intelligently treat these otherwise puzzling conditions.

Farmers' Clean Milk Book. By Charles Edward North, M.D., Director, North Public Health Bureau, New York City. Cloth. Price, $1.00 net. New York: John Wiley & Sons, 1918.

This little book is intended primarily for the use and instruction of the progressive farmer. It is fully illustrated with photographs, and will doubtless be of material service in furthering the production of sanitary milk. Chapter 12, entitled "The Dairy Man More Important than the Dairy," describes a striking instance of the production of milk with a low bacterial count by simply shifting milkers from one farm to another. The book will be appreciated by all interested in the production of clean milk.

Elements of Hygiene and Public Health. For the Use of Medical Students and Practitioners. By Rai Bahadur Jaising P. Modi, L.R.C.P. & S., L.F.P.S., Lecturer on Medical Jurisprudence, Hygiene, Chemistry and Physics, Agra Medical School. With an Introduction by Lieut.-Col. E. J. O'Meara, F.R.C.S., D.P.H., I.M.S., Principal, Agra Medical School. Cloth. Price 4 rupees net. Pp. 337, with 69 illustrations. Calcutta: Butterworth & Co., 1918.

This book is written with special reference to conditions existing in India and the East. It is intensely practical, and the numerous "shoulds" and "should nots" make evident the class of reader for whom it is intended. The directions given for furthering sanitation and preventing disease are, on the whole, clear and sensible. The book contains an important chapter on village sanitation and one on fairs, famine camps and poorhouses, both of which deal in detail with the peculiar conditions in India. Altogether, the book ought to be of great service to those directly concerned with Asiatic conditions of life. The paper used in the book deserves special mention; it is so thin that much valuable material is included in a relatively small bulk, and yet sufficiently opaque as to make it easy to read. The book is printed in India, and evidently this is true "Indian" paper.

Medicolegal

Automobilist Liable on Verbal Promise to Pay for Care of Injured Boy

(Banfield v. Davidson (Texas), 201 S. W. R. 442)

The Court of Civil Appeals of Texas affirms a judgment in favor of Plaintiff Davidson for $291.45, the amount sued for, for the care and treatment at his hospital of a boy, named Johnny Van, who was injured and brought there by defendant Banfield. The court thinks there was sufficient evidence to support a finding by the jury that the defendant negligently ran his automobile against the boy, who was at the time riding a bicycle, and that by such negligent act the boy's leg was broken, and other injuries inflicted on his body; that the boy was immediately taken by the defendant to the plaintiff's hospital, and that on reaching the hospital the defendant told the plaintiff to take the boy into his hospital and give him all necessary attention, and to try to save his life, and that the defendant would pay the plaintiff for such services, etc.; that the plaintiff did take the boy into his hospital on such request of the defendant, and did give him all necessary medical treatment and hospital accommodations and attention, as requested by the defendant, for about six weeks, and that such medical services, etc., were reasonably worth $291.45.

The defendant denied making any such promise, either expressly or by implication, and said further that if he did make such promise the same was verbal only and not in writing, and that as the sum due the plaintiff was the debt of Johnny Van, and not the debt of the defendant, the defendant could not be held liable therefor, and he specially pleaded the statute of frauds, which provides that no person shall be held liable for the debt, default or miscarriage of another, unless such person shall by some agreement or memorandum in writing, signed by the promisor or by some person by him authorized, promise to pay such debt, default or miscarriage of the other. But the court holds that the agreement to pay the plaintiff for his services was an original undertaking of the defendant. There was no contention by either party that it was alleged in the pleadings of either party or shown by the evidence that medical services or hospital accommodations given to Johnny Van were first performed, and thereafter a promise was made by the defendant to pay the reasonable value for such services, etc. There was no evidence calling for a charge on the statute of frauds. The cause of action alleged and proved was not within the statute of frauds.

The trial court gave the jury the following special charges requested by the plaintiff:

> A promise to pay for services rendered to a third person at the promisor's request is an original undertaking, not within the statute of frauds. Therefore, if you find from the evidence in this case that defendant promised to pay plaintiff for the services rendered Johnny Van, if any, by plaintiff, and that such services were rendered said Johnny Van at the request of defendant, then such promise need not be in writing, and defendant would be liable to pay for the reasonable value of such services, and if you so find by a preponderance of the evidence, you will find for the plaintiff in such amount as you may find the reasonable value of such services. . . .
>
> Where one does for another that which the other is legally obligated to do, the law not only implies a previous request that the thing should be done, but a promise to compensate. Therefore, if you find in this case that defendant was driving his car at a reckless and

at times indicates that the basic lesion is susceptible of repair, wherever situated. Porter's conclusions relative to fat embolism, enforced inhalation of carbon dioxid, were apparently largely founded on examination of cases a good many hours after injury. Lowering of the alkali reserve in the blood after anesthesia and operative attacks, and the beneficial effect of intravenous use of alkaline solutions have seemed to indicate a possible relation between shock and acidosis. Henderson and Haggard see a suggestive cause of surgical shock in a connection between the excessive respiration due to pain and the carbon dioxid capacity or alkali reserve of the blood. For prevention of shock there must be avoidance of fall of blood pressure, prevention of pain, and control in severity of traumatism. Ether, the most satisfactory of the usually inhaled anesthetics, is said to reduce blood pressure, and is toxic to nerve tissue and glandular organs. Nitrous oxid with ether following, or in association with nerve blocking, is at times available. Geoffrey Marshall uses nitrous oxid gas with oxygen to lessen shock in amputation. He says that shock evades exact definition. I fear his experience is more that of an anesthetist than of an operating surgeon. Porter finds that a diastolic blood pressure of from 45 to 50 mm. continued for a considerable time in a laboratory animal is followed by death by transfer of blood to the portal veins unless the animal is saved by surgical treatment. Treatment, therefore, requires that the blood pressure of the wounded, in war or civilian practice, be raised above the critical point. Elevation of the feet and intravenous injection of saline solution will raise diastolic blood pressure to 70 or 80 mm.; such procedure is to be used in addition to elevation of legs and trunk. Epinephrin may be employed in addition if the pressure falls again. Too much saline solution may increase hemorrhage in oozing wounds, unless hemostasis or operation and hemostasis have been successfully employed. Transfusion of blood is then acceptable, but hemostasis must also be looked after. External heat is of the highest importance. Pressure is to be made on the wound and not by tourniquet above the wound. Geoffrey Marshall's objection to morphin is probably founded on anesthetic observations rather than on the study of clinical surgery as an operating surgeon. C. L. Gibson of New York strongly advises the use of morphin to prevent shock, stating that its generous use makes the journey of the wounded man to the next station comfortable; also that it has been found to be of great value previous to operations with a marked effect in diminishing shock. The preliminary hypodermic use of morphin and atropin will probably convince operators that Geoffrey Marshall's objection to ether in amputation cases is probably not well founded. Surgeons must remember that saline solution is not well absorbed in shock cases; it may take some time to get the beneficial effect of gravity and intravenous medication. Frequent blood pressure observations combined with temperature observations will determine the indications for cessation or diminution of activity in treatment.

DISCUSSION

Dr. S. J. Meltzer, New York: The theory of acapnia assumes that shock is due to a diminution of carbon dioxid in the blood of patients in shock. This assumption suggests the treatment—letting the patient breathe some carbon dioxid or respire through a long tube or, as it is termed for short, rebreathing. If the statement that the carbon dioxid of the blood is decreased in shock were generally confirmed, the fact of the reduction of carbon dioxid could not prove the correctness of the acapnia theory. The reduction of carbon dioxid may merely be a consequence of shock and not the cause of it. Geoffrey Marshall, an expert anesthetist, is of the opinion that rebreathing is rather a dangerous procedure and ought not to be used in shock patients. Acapnia and rebreathing, as far as the science of physiology is concerned, are dying. Cannon studied shock experimentally as well as clinically. He believes that the most essential factor in the production of shock is acidosis and advocates the treatment of shock by the administration of sodium bicarbonate. Bayliss gave up the idea that acidosis is of primary importance in shock, and lost faith in the value of the alkaline treatment of shock. The theory that shock is produced by pulmonary fat embolism received a great deal of attention. No doubt there are cases in which fracture of the long bones or injuries to fat tissues lead to pulmonary fat embolism and to a dangerous and even to a rapidly fatal fall of blood pressure. But these facts are in no way new. Fat embolism, a grave condition, presents a number of definite clinical symptoms outside of the presence of low blood pressure. There are, in the first place, symptoms that point directly to the lungs as the seat of trouble. The patient is suffering from air hunger, dyspnea; pulmonary edema and even hemoptysis are frequently present. On auscultation, râles may be discovered. Fat is present in the circulation in abnormal quantities. The urine contains fat globules. Even the sputum may reveal fat. Porter recommends the inhalation of carbon dioxid for the treatment of shock, and reports that he has helped many such patients by this treatment. Porter administers carbon dioxid not for the purpose of meeting the possible exigencies of acapnia but for the purpose of producing deep inspirations, which would help drive the blood from the engorged abdominal veins into the half empty heart. Wiggers says that if the circulation from the right ventricle is impeded by capillary emboli in the lungs, the introduction of larger quantities of blood into the right ventricle might lead to the dilatation of that ventricle and to death. According to Wiggers, shock is distinguishable from pulmonary fat embolism by the difference of the pressure in the right ventricle and the pulmonary artery; in pulmonary fat embolism the pressure is rather high, while in shock it is low. Therefore, while in shock it is advisable to drive the blood from the veins of the abdominal cavity into the right ventricle, this procedure has to be avoided in cases of pulmonary fat embolism. Neither Porter's theory of shock nor his therapeutic advice rendered a practical service to medicine.

The Ductless Glands in Military Practice

Dr. Charles E. de M. Sajous, Philadelphia: So far as recruits are concerned, proper recognition of the diseases of the ductless glands and their treatment would enable a large proportion of men now deemed unfit to continue their service. As for the armies in the field, it is a question of life and death in the large proportion of cases of disease of the suprarenals or of the thyroid, including many cases of so-called "soldier's heart," as regards the latter organ. All this should be taken to heart by our military authorities, if their excellent work in other directions is to encompass all fields of suffering.

DISCUSSION

Dr. John A. Lichty, Pittsburgh: In considering the disturbances of internal secretion there are always two points that come out necessarily. One of these is the early recognition of disturbance of function in typical cases; the other is the recognition of the aberrant cases. The treatment depends entirely on the stage at which the case is met. In the thyroid or other glands of internal secretion, if a case is met at a time when only the vegetative nervous system is affected, surgery, of course, is not to be considered. These are the cases in which rest is the factor. If the condition gets to a certain point where neither of these factors, rest, forced feeding or the administration of an internal secretion are helpful, when it has gone beyond our control, we might say, then, of course, some direct effect on the gland itself will have to be brought about; and under these circumstances, surgery will no doubt be called into play.

Dr. E. Bosworth McCready, Pittsburgh: The reports of the Army medical examiners show how prevalent are organic and functional defects of development among the adult male population. Surveys of large groups of children have shown the existence of malnutrition to an almost incredible degree. It is to a large extent these malnourished, asthenic children who later develop glandular anomalies. Food quality and food quantity is a factor in metabolism, but only a factor. Metabolism depends on a proper balance of all physiologic functions, particularly on those of the ductless glandular apparatus. Preventive treatment should begin before the child is born, through proper parental care, including, when indicated, the administration of ductless gland preparations to the mother.

26. **Study of Pneumonia.**—Only completed cases of pneumonia treated at the U. S. Army Base Hospital, Fort Riley, Kan., from Oct. 18, 1917, to May 18, 1918, are included in this report on a series of 668 instances of lobar pneumonia, 181 instances of measles pneumonia, and twenty-two instances of bronchopneumonia. The total incidence for pneumonia was 4.5 per cent., with a mortality of 23 per cent. The mortality of lobar pneumonia without empyema was 12.7 per cent. The incidence of pneumonia in measles was 6.1 per cent., with a mortality of 45.8 per cent. The mortality of measles pneumonia without empyema was 32.5 per cent. Among the twenty-two instances of bronchopneumonia there were no empyemas, but there were two death, a mortality of 9 per cent.

The mortality with the same general plan of treatment varied from month to month in this series of pneumonias. The fatality of empyema likewise varied from month to month under the same general plan of treatment. The highest mortality in which empyema was the prominent associated pathologic condition occurred during the months of March and April. These were largely instances of overwhelming infection of rapid onset and death within a few days. The rapid onset of chill, fever and cough with tubular breathing and signs of consolidation, however small, sufficed, in the vast majority of cases, to establish the diagnosis. The roentgenogram may be of great help in making a diagnosis of questionable consolidation. In the diagnosis of bronchopneumonia some dependence should be placed on the history of previous bronchitis or measles. In the diagnosis of complications the aspirating needle was used early for the detection of empyema. Pus was frequently found without any increase in the temperature. The roentgen ray was of little help in small accumulations of fluid, but was of great help in outlining larger accumulations associated with fibrinoplastic pleural thickening. Pericarditis occurs frequently enough in pneumonia to make it an imperative rule to examine the heart with care at each visit. Serofibrinous pericarditis occurred clinically in approximately 4 per cent. of lobar pneumonias, in 2.2 per cent. of measles pneumonias. There were thirty-one instances. Twenty-four of the patients died. Pericarditis purulenta occurred only in association with empyema of subcostosternal pus pockets. Of this complication there were twenty instances, in all of which death occurred. Diphtheria was simulated in two instances by edema of the glottis incidental to a streptococcic infection. Acute peritonitis was diagnosed in five moribund patients in whom the condition was not found at necropsy.

Subcostosternal pus pockets were found in twenty-nine instances in 153 necropsies, and the diagnosis was not possible prior to death in any case, although the presence of such purulent accumulations were suspected in many instances from the combination of clinical and roentgen-ray evidence. This pocket of pus, which is usually situated on the side of the affected lung, but which may be bilateral, lies immediately beneath the sternum. It occupies the space between the median flap of lung composing the upper lobe as it lies above the fibrous layer of the pericardium. It is not in the mediastinum and should not therefore be called a mediastinal abscess. The pocket may communicate with other septal pockets or other portions of the pleura of the affected side. The vessels of the hilum may be its deepest limit or the opening to the pleura may occur through the normal pulmonary septa. This pocket is almost impossible to drain laterally, anteriorly or posteriorly by the usual thoracotomy or costatectomy. This pocket may be affected primarily and all other portions of the pleura be apparently free from pus while this one alone remains undrained and unhealed. The authors believe that the course of the infection is parietal rather than visceral, that it follows the lymph channels to the pleura from which afferent lymph vessels draining the anterior chest wall including the anterior parietal pleura, lead to sternal lymph nodes of which there are usually six on each side along the course of the internal mammary arteries. The pus pockets occur in close proximity to these nodes due undoubtedly to breaking down of these glandular structures. They have constituted a unique and very serious complication.

So-called toxic arthritis occurred in ten instances of empyema. Only one patient developed a suppurative arthritis in association with empyema in this series.

Blood cultures were taken from 100 patients with pneumonia, or suspected pneumonia, on admission. In one instance a hemolytic streptococcus was obtained from a patient with bronchopneumonia whose sputum also contained the same organism. In five instances a pneumococcus was obtained, in two of which the patients did not develop pneumonia. The cultures were sterile in 94 per cent. Sputum determinations as to type of infection were made in 428 completed cases of pneumonia. The hemolytic streptococcus was found in 28.2 per cent. of the cases; pneumococcus Type II, in 21 per cent. In 155 empyema fluids the hemolytic streptococcus was found in 68.4 per cent., the nonhemolytic streptococcus in 5.8 per cent. The mortality in empyema, due to the streptococcus, was 61.7 per cent., while in empyema, due to the pneumococcus, the mortality was 45 per cent. Cole Type I serum was administered in doses of 100 c.c. intravenously after desensitization in Type I lobar pneumonias. Its effect was, in a large percentage of cases, immediately beneficial. This serum was administered in twenty-seven of the thirty-two cases. Among those who received the serum there were four deaths (two had meningitis and one had bilateral empyema mentioned above). The mortality in the serum treated patients was therefore 14.8 per cent. The autolyzed pneumococcic antigen of Rosenow was used in seventy patients with lobar pneumonia not due to Type I pneumococcus. The mortality was 12.8 per cent. Among 219 completed instances of lobar-pneumonia in which the patients were discharged during the same period and not treated with the antigen, the mortality was 14.6 per cent. The dosage of the antigen, 1 to 2 c.c. daily, subcutaneously, for four or five doses, produces practically no reaction. Keys' antipneumococcic chicken serum was used in thirty cases of lobar pneumonia due to the pneumococcus. One death occurred, a mortality of 3.3 per cent., with an empyema incidence of 13.3 per cent. During the corresponding period the mortality of lobar pneumonia in patients not treated with this serum was 14.2 per cent. The serum seemed to possess value in reducing the toxemia in pneumonia.

Measles patients received, since Feb. 15, 1918, a vaccine prepared from five local strains of streptococci and two strains of Pneumococcus IV. The incidence of measles pneumonia, prior to the use of the prophylactic vaccine was 6 per cent. The incidence of measles pneumonia in 148 cases in which the prophylactic vaccine was used was 2 per cent. Antistreptococcus serum was used intravenously, after desensitization, in measles pneumonia due to the streptococcus with beneficial results in many instances.

The total number of empyema complications following pneumonia in this series was 200. Of this number 119 men were operated on. In the cases (eighty-three) in which early operation was done, not preceded by repeated aspirations, the mortality was 63.8 per cent. In the cases in which late operations were done, preceded by repeated aspirations, the mortality was 22.2 per cent.

27. **Pneumonia and Empyema.**—In lobar pneumonia the mortality for the entire period from the opening of the hospital at Camp Sevier until March 31, 1918, was 14.9 per cent. The highest number of deaths occurred during the early days of the hospital. In a period from Dec. 1, 1917, until March 31, 1918, during which more accurate records were kept, type determination was made, better methods of isolation were employed and the treatment was supervised in all wards by one person, the mortality was decidedly lower, being 10 per cent. In this second period nearly all of the cases fall, 201 out of 234. The death rate with Type I pneumonia is recorded as 14 per cent., and from Type IV as 7 per cent. There were no deaths among the eleven cases of Type II pneumonia. The Type I mortality includes both serum treated cases and those not so treated. In bronchopneumonia the death rate has been 36 per cent. Vaughan and Schnable consider Type I immune serum as being a most valuable addition in the treatment of pneumonia. It should be used in all cases of Type I infection; the earlier in the course of the disease the more satisfactory will be the results. Polyvalent serum was used in a few cases of severely ill bronchopneumonias and without beneficial results.

28. **Treatment of Bronchial Asthma with Proteins.**—The results of the treatment of 100 sensitive patients with the proteins to which they were sensitive are recorded by Walker. Of forty-eight patients who were sensitive to and treated with horse dandruff proteins, 63 per cent. were relieved of asthma, 10 per cent. have had too little treatment to warrant a prognosis, and 20 per cent. were relieved by vaccines or by omitting foods to which they were sensitive; in the remaining 7 per cent. of this group treatment was a failure. Of four patients who were sensitive to and treated with cat hair protein, three were relieved of asthma, and the other patient, who was equally sensitive to the horse dandruff proteins, was relieved by treatment with them. Of thirty patients who were sensitive to the cereal grains, 74 per cent. were relieved by the omission of these from the diet, and 7 per cent. were relieved by vaccines; of the 26 per cent. who were not relieved by the omission of cereals from the diet, in 16 per cent. there was no evidence that cereals played any part in the cause of asthma, but the presence of eczema may account for these positive skin tests. Of thirty-three patients who gave positive skin tests to other foods, 50 per cent. were relieved by the omission of these from the diet, 30 per cent. more were relieved of asthma, but as the latter were also sensitive to other proteins which were also omitted from the diet at the same time, it is difficult to give credit to any special protein. The remaining 20 per cent. were not relieved of asthma, but the presence of eczema and urticaria and an acquired distaste for certain foods probably explains the idiosyncrasy. Therefore, of the total number of 100 sensitive individual patients who were treated as indicated by the positive skin tests, in 75 per cent. there was relief from asthma, in 14 per cent., although there was no relief from asthma, there was a definite idiosyncrasy substantiating the positive skin test; but in 11 per cent. the positive skin test had no apparent bearing on the patient's condition, although in only half of these, or 5 per cent., was there evidence that the skin test gave a false result. Since the 11 per cent. includes 7 per cent. who were relieved by vaccines, a total of 82 per cent. of the sensitive patients were relieved from asthma.

32. **Bronchial Asthma.**—Some of Rackemann's conclusions may be summarized as follows: "Bronchial asthma" is a symptom of some other disease condition. The 150 cases of asthma studied can nearly all be divided, according to the etiology of their attacks, into various subgroups under the general headings of "extrinsic asthma" and "intrinsic asthma." Extrinsic asthma includes 28 per cent.; intrinsic asthma includes 53 per cent. of the entire group—the other 19 per cent. being unclassified. A history of either asthma, hay-fever or food poisoning, in the immediate family, occurs in 58.7 per cent. of the cases of extrinsic asthma, but in only 10.5 per cent. of the cases of intrinsic asthma. Skin tests are of great assistance in confirming the diagnosis. Skin tests alone are of no value unless reasonably compatible with the patient's history or experience. A positive skin test is a necessary preliminary to successful specific treatment. The "nervous" element is very important in asthma, but probably does not explain why certain individuals have asthma. Treatment resolves itself into the treatment of the exciting cause. Various different therapeutic procedures sometimes yield favorable results, but these cannot be explained. The real problem—what is the fundamental disturbance of anatomy or physiology which expresses itself by attacks of asthma—remains unsolved.

36. **Myrtol Poisoning.**—Derivatives of plants belonging to the natural order *Myrtaceae*, and especially oil of eucalyptus

and myrtol, may in large doses cause profound intoxication. In certain persons, there is an idiosyncrasy, the symptoms of intoxication occurring after minute or therapeutic doses. The authors report one case and summarize thirty-five cases recorded in the literature. The intoxication may affect chiefly the nervous system (myrtogenic neuropathy) or chiefly the skin (myrtogenic dermatopathy); in some persons, nervous and cutaneous manifestations are simultaneously observable. Recovery occurs in most instances, though several fatalities following eucalyptus poisoning have been reported. The symptoms of intoxication of the nervous system observed in man can be reproduced in animals by subcutaneous and by intraperitoneal administration of myrtol.

The authors' patient suffered from bronchiectasis; bronchitis chronica putrida; peribronchitis fibrosa; pleuritis chronica dextra. In addition to general measures, 3 minims of myrtol in capsules thrice daily were prescribed on account of the fetid bronchitis. The patient had been taking some oil of eucalyptus and oil of sandalwood before. These he continued along with the myrtol. After having taken two capsules three times a day for eight days the face became discolored and large puffs came under each eye. The forehead looked as if it were going to break out with eczema. The left eye became nearly closed and the right partially closed from the swelling. The myrtol was stopped at once, but the swelling lasted for many days. The cough increased markedly and the heart's action became more rapid, and he was greatly depressed. The patient had been told to increase the dose of myrtol gradually until twelve capsules per day were taken, but the myrtol was stopped when only six capsules per day were ingested.

37. **Dakin's Solution and Dakin's Oil in Normal Peritoneal Cavity.**—Observations are reported by Grey in order to draw attention to the fact that the indiscriminate use of the chlorin antiseptics is not entirely devoid of danger. Both the neutral solution of chlorinated soda (Dakin's solution) and dichloramin-T in chlorinated paraffin (chlorcosane, N. N. R., "Dakin's oil"), when injected into the normal peritoneal cavity of a dog, led to an inflammatory reaction, the degree of which was directly proportional to the amount of chlorin antiseptic used. With a sufficient quantity (less chlorcosane suffices) death ensued. When either of the chlorin antiseptics was injected into the gallbladder of a dog no abnormal symptoms appeared. Following the injection of chlorcosane, however, the gallbladder becomes thickened and shrunken, though the remainder of the biliary tract shows no discernible changes. A small amount of chlorcosane, when injected into the normal pleural cavity of an unanesthetized dog, may lead to a rapid (reflex?) death.

Since chlorcosane, particularly, has been used without recognizable ill effects in certain infections of the abdominal cavity, the results from the experiments made by Grey suggest that the wall of an abscess cavity or sinus must play an important part in protecting the peritoneum in general from the effects of the free chlorin. They also suggest that the maintenance of an adequate drainage tract is an indispensable part of the technic for using antiseptics of this nature within the abdomen. Until more evidence is at hand, then, both of the chlorin antiseptics should be used in intra-abdominal infections with caution and certainly only in carefully selected cases.

38. **Multiple Primary Malignant Tumors.**—Major's patient was a woman, 60 years of age. She applied for treatment of a carcinoma involving the right side of the nose and extending to the inner canthus of the right eye. While in the hospital the patient complained a great deal of headache, had little appetite and at times talked irrationally. Death occurred rather unexpectedly. The necropsy disclosed a round-cell sarcoma of the stomach. Hence this is a case of two primary malignant growths being present in the same person at one time. One hundred and ninety-six references to similar cases are given by Major.

40. **Cerebrospinal Fluid Findings in Herpes Zoster.**—A lumbar puncture was performed in 21 cases of 79 cases of herpes by Schaller. In 14 cases in which a blood Wassermann alone was done 4 cases showed a positive reaction and 10 a negative reaction. The remaining 44 cases were not examined by the blood or fluid tests, nor were they clinically cases of syphilis. Nine occurred in syphilitic persons and in all but 1 of these the fluid showed a characteristic reaction of syphilis of the central nervous system. Eleven cases were negative for syphilis. However, in 5 out of these 11 cases there was a cellular increase above the normal. The globulin test in these 5 cases was negative or slightly increased. Schaller concludes that herpes zoster occurs with comparative frequency as symptomatic herpes in syphilis of the central nervous system. In nonsyphilitic herpes an increased cell count may mislead the clinician if other evidence suspicious for syphilis is brought out in the general survey of the case.

57. **Ocular Lesions Produced by Mustard Gas.**—Warthin and his associates made a very thorough experimental and clinical study of this subject. The results are presented in detail. Summarized they are as follows: The action of mustard gas on the cornea and conjunctiva is essentially the same as that on the skin. The conjunctiva is, however, less susceptible to the action, or better protected, as the degree of necrosis produced in it is always less than that in the cornea or the epidermis. Exposures to dilute concentrations of the vapor produce slight degenerations of the corneal and conjunctival epithelium followed by a simple conjunctivitis. The use of a 2 per cent. alkaline aqueous fluorescein solution in demonstrating the necrosis of the corneal epithelium within ten to fifteen minutes after exposure to gassing has great clinical value. Exposures to stronger concentrations produce a more or less complete necrosis of the corneal vertex, extending throughout the entire depth of the cornea. Purulent exudation in the anterior chamber may occur; but no changes except congestion and edema were observed in the posterior chamber or optic nerve in noninfected cases.

In severe cases iridocyclitis and iritis may occur without secondary infection. The conjunctival epithelium also suffers necrosis, and there results an intense edema of the subconjunctival tissues with marked congestion, multiple hemorrhages, leukocyte infiltration, and frequently secondary liquefaction necrosis. The depth of the necrosis in the conjunctiva is much less than that in the palpebral epidermis. This difference in degree of escharization can be explained, in part, by the penetration of the hair follicles on the skin surface, and in part by the moistness of the conjunctival surfaces and the lacrimation. A diffuse mild inflammation of the peribulbar tissues occurs, often with marked infiltration of the ocular muscles. No metastatic lesions of the eye could be produced experimentally by applications of mustard gas to other regions of the body, or by subcutaneous or intraperitoneal injections.

For the milder forms of mustard gas conjunctivitis the authors recommend immediate irrigation with the 0.5 to 1 per cent. chlorcosane solution of dichloramin-T followed by frequent irrigation with saturated boric acid solution. For the severe forms the same initial treatment followed by frequent irrigations with the dichloramin-T alternating with boric acid. They advise against the use of bandages or compresses bringing pressure on the eye, against the use of colloidal silver preparations, and against the use of cocain. During exposure to mustard gas vapor the dichloramin-T solution may be used as a prophylactic agent. Healing in the more severe forms results in vascularization and cicatrization of the cornea with marked disturbances in vision. Even in the milder forms of conjunctivitis, localized roughness or irregularity in the conjunctival surface may persist for weeks as the result of localized edema, hyperemia, cellular infiltration, etc. Serious refractive errors and reduction of vision result, even in mild cases. For the correction of the disturbances of vision the patient should be referred to a competent specialist.

58. **Treatment of Mustard Gas Injuries.**—The clinical resemblance of mustard gas lesions *of the skin to thermal* burns has led to the use of alkalis externally and to the application of air-excluding protectives, such as oils, pastes, ointments, pomades, paraffin, oiled paper, dusting powders, etc. The extensive use abroad of a 10 per cent. bicarbonate solution is the result, no doubt, of its employment in the treatment of other forms of gassing. From the laboratory standpoint and theoretically it became very evident to Warthin and his co-workers that any form of treatment covering the surface of the injured skin areas and forming an air-*excluding and germ-including* coating was the worst possible *method of treatment.* Animal experiments with zinc stearate and other forms of oily coatings confirmed this view.

Inasmuch as mustard gas causes a necrosis, more or less deep, of the skin, cornea and conjunctiva, and mucous membrane of the respiratory tract, the therapeutic problems are as follows: 1. To sterilize the dead tissue and prevent infection of the eschar. 2. To prevent further necrosis by removing pressure. 3. To promote removal of the eschar and rapid regeneration and healing without secondary infections. The use of neutral solution of chlorinated soda suggested itself as an ideal method particularly, because the use of a chlorinating solution would also serve to destroy any mustard gas remaining in the skin, hair follicles, or sweat glands. The use of the bath method, as carried out in the treatment of severe thermal burns and necrotic and suppurative conditions of the skin, and especially, because of the danger of bedsores and secondary necrosis from pressure, is founded on the pathology of the lesions produced by mustard gas, and is based on scientific principles. In practice it has produced good results.

A. Mild Injuries.—Wash immediately, or better, *immerse* parts one half to two hours in neutral solution of chlorinated soda (strength of about 0.5 per cent. hypochlorous acid). If too irritating, dilute the solution or shorten time of immersion. If injured surfaces are very large, use full bath; for lesions of the genital region use *sitz bath. When immersion* of parts is not expedient, use dressings wet with or irrigate with neutral solution of chlorinated soda. *If the wet treatment* (which the authors consider *by far the best*) cannot be carried out, the application of dichloramin-T in chlorcosane or chloramin-T in sodium stearate *may* be used. These procedures will serve a double purpose of chlorinating and rendering inactive any dichlorethylsulphid remaining in the skin, hair follicles, etc., and also disinfecting the damaged skin surface. This primary disinfection of the skin is of very great importance in the prevention of the secondary infections that are so often of a serious character.

After the neutral solution of chlorinated soda, use wet dressings, irrigation or bath of sterile hypertonic saline (5 to 10 per cent.), alternating with the neutral solution of chlorinated soda, and a sterile physiologic saline, according to judgment, about as follows: Neutral solution of chlorinated soda one to two hours, hypertonic saline two hours, physiologic saline one hour, and then repeat until lesions appear and extent of injury can be determined. As long as the lesion remains an erythema continue this treatment during the daytime. At night, dry the skin under aseptic precautions, and apply a vanishing surgical cream containing hypochlorous acid or liberating chlorin, of the type of the chlorazene (chloramin-T, 1 per cent. in sodium stearate) surgical cream, or instead, use wet hypertonic saline dressings.

Dusting powders are inadvisable because of crusting and possibility of infection. Chloramin-T and dichloramin-T in full strength powder form are too irritating. The authors have had no experience with Vincent's powder but on general principles would not favor its use. They also advise against the use of silver nitrate, iodin, potassium permanganate, or other local applications. Saturated magnesium sulphate solution proved irritating and no benefits were observed from its use.

In the case of vesicle formation, empty vesicles early under aseptic precautions, by means of a hypodermic syringe or sterile needle with slight pressure *on the vesicle,* and allow *intact vesicle wall to collapse and seal down on* its base. After this procedure, continue with alternating neutral solution of chlorinated soda and sterile salines, as above. If vesicles are not drained early, the fluid content may, within four to five hours, coagulate to such an extent that a large coagulum is formed that cannot be removed, and forms a possible medium for bacterial growth. It is very important that skin damaged by mustard gas be protected from trauma. Slight injuries, even ordinary pressures of the body, will cause the development of secondary vesicles or decubitus in the injured areas.

The use of unguents and ointments with oily bases, such as zinc stearate, olive oil, oleum petrolatum, or any form of crude petrolatum or other protecting oil, or such air-excluding and infection-including protectives as oiled paper, paraffin sprays and coatings, such as are employed in the treatment of thermal burns, *is strongly* condemned in the treatment of *dichlorethylsulphid injuries. The principle* of excluding the *air for the purpose of lessening pain* in the treatment of thermal burns *is not applicable here* because of the relative anesthesia *of the* dichlorethylsulphid lesions in their earlier stages. *Exceptions to the above rule are* the *sodium* stearate impregnated with chloramin-T and the chlorcosane solution of dichloramin-T, as in these cases there is an active and persistent germicidal agent present.

In the case of denuded surfaces with much pain and when *bedsores have developed,* the colloidal saline bath is strongly advocated. *This bath is made* as follows: Dissolve 1 pound of commercial *cornstarch* and 1 pound of sodium bicarbonate in *20* to *30* gallons of *sterile physiologic* salt solution, at a temperature of 90 to 95 F. The *patient* can be *left immersed* in this, when necessary, from fifteen *minutes to forty-eight* hours. The patient should be *constantly* watched by the nurse. Should pulse become weak, give *strychnin* or digipuratum or any other active digitalis *preparation,* or remove from bath, and apply blankets and heat.

B. Severe Injuries.—When necrosis of the *skin, more* or less extensive, develops, follow the same *line of* treatment given above: full bath, irrigation, slush or sponge bath, or wet packs of neutral *solution of* chlorinated soda, alternating with physiologic and *hypertonic* salines, or the colloidal bicarbonate bath should be constantly employed. Avoid bedsores. For this purpose the constant colloidal or saline bath, with patient hung in canvass body cradle to take off pressure should be used. It is of the greatest importance to protect the damaged areas from secondary trauma. In cases in which decubitus or sloughs occur the necrotic layer should be removed, either with sterile forceps or by means of frequent hot irrigations under pressure. For this purpose saline, neutral solution of chlorinated soda, 1:10,000 potassium permanganate solution, etc., should be used. If the necrotic areas have become infected through neglect or improper treatment, the use of neutral solution of chlorinated soda or a similar solution should be pushed, alternating with hypertonic saline baths.

A hyperchlorous solution made according to Carrel's method can be applied here with good results: To 1 liter of water add 12.5 gm. of bleaching powder, shake vigorously, then add 12.5 gm. of boric acid powder, and shake again. Allow the mixture to stand for some hours, preferably overnight, then filter off, when the clear solution is ready for use. This solution contains about 0.54 per cent. of hypochlorous acid, 1.28 per cent. calcium biborate and 0.17 per cent. calcium chlorid. This is about the most practical concentration of hypochlorous acid, as stronger solutions rapidly lose strength. When the patients are very weak, temperature rising, and infection progressing it may be advisable to employ tepid sponge baths of the foregoing solutions.

59. **Studies on Cholesterol.**—Cholesterol promotes cell multiplication; high blood cholesterol values must, therefore, says Luden, further malignant growth. High blood cholesterol values are commonly found in carcinoma. Radium treatment and the administration of the thyroid hormone both reduce the cholesterol content (Bloor I) of the blood, and increase the amount of changed cholesterol in the blood (namely, the difference between the Bloor I and II values). The high cholesterol values in myxedema are brought down to normal by the administration of the thyroid hormone at a rate parallel to the rise in basal metabolism induced by the latter.

necrosis, and there results an intense edema of the subconjunctival tissues with marked congestion, multiple hemorrhages, leukocyte infiltration, and frequently secondary liquefaction necrosis. The depth of the necrosis in the conjunctiva is much less than that in the palpebral epidermis. This difference in degree of escharization can be explained, in part, by the penetration of the hair follicles on the skin surface, and in part by the moistness of the conjunctival surfaces and the lacrimation. A diffuse mild inflammation of the peribulbar tissues occurs, often with marked infiltration of the ocular muscles. No metastatic lesions of the eye could be produced experimentally by applications of mustard gas to other regions of the body, or by subcutaneous or intraperitoneal injections.

For the milder forms of mustard gas conjunctivitis the authors recommend immediate irrigation with the 0.5 to 1 per cent. chlorcosane solution of dichloramin-T followed by frequent irrigation with saturated boric acid solution. For the severe forms the same initial treatment followed by frequent irrigations with the dichloramin-T alternating with boric acid. They advise against the use of bandages or compresses bringing pressure on the eye, against the use of colloidal silver preparations, and against the use of cocain. During exposure to mustard gas vapor the dichloramin-T solution may be used as a prophylactic agent. Healing in the more severe forms results in vascularization and cicatrization of the cornea with marked disturbances in vision. Even in the milder forms of conjunctivitis, localized roughness or irregularity in the conjunctival surface may persist for weeks as the result of localized edema, hyperemia, cellular infiltration, etc. Serious refractive errors and reduction of vision result, even in mild cases. For the correction of the disturbances of vision the patient should be referred to a competent specialist.

58. **Treatment of Mustard Gas Injuries.**—The clinical resemblance of mustard gas lesions of the skin to thermal burns has led to the use of alkalis externally and to the application of air-excluding protectives, such as oils, pastes, ointments, pomades, paraffin, oiled paper, dusting powders, etc. The extensive use abroad of a 10 per cent. bicarbonate solution is the result, no doubt, of its employment in the treatment of other forms of gassing. From the laboratory standpoint and theoretically it became very evident to Warthin and his co-workers that any form of treatment covering the surface of the injured skin areas and forming an air-excluding and germ-including coating was the worst possible method of treatment. Animal experiments with zinc stearate and other forms of oily coatings confirmed this view.

Inasmuch as mustard gas causes a necrosis, more or less deep, of the skin, cornea and conjunctiva, and mucous membrane of the respiratory tract, the therapeutic problems are as follows: 1. To sterilize the dead tissue and prevent infection of the eschar. 2. To prevent further necrosis by removing pressure. 3. To promote removal of the eschar and rapid regeneration and healing without secondary infections. The use of neutral solution of chlorinated soda suggested itself as an ideal method particularly, because the use of a chlorinating solution would also serve to destroy any mustard gas remaining in the skin, hair follicles, or sweat glands. The use of the bath method, as carried out in the treatment of severe thermal burns and necrotic and suppurative conditions of the skin, and especially, because of the danger of bedsores and secondary necrosis from pressure, is founded on the pathology of the lesions produced by mustard gas, and is based on scientific principles. In practice it has produced good results.

A. Mild Injuries.—Wash immediately, or better, immerse parts one half to two hours in neutral solution of chlorinated soda (strength of about 0.5 per cent. hypochlorous acid). If too irritating, dilute the solution or shorten time of immersion. If injured surfaces are very large, use full bath; for lesions of the genital region use sitz bath. When immersion of parts is not expedient, use dressings wet with or irrigate with neutral solution of chlorinated soda. If the wet treatment (which the authors consider by far the best) cannot be carried out, the application of dichloramin-T in chlorcosane or chloramin-T in sodium stearate may be used. These procedures will serve a double purpose of chlorinating and rendering inactive any dichlorethylsulphid remaining in the skin, hair follicles, etc., and also disinfecting the damaged skin surface. This primary disinfection of the skin is of very great importance in the prevention of the secondary infections that are so often of a serious character.

After the neutral solution of chlorinated soda, use wet dressings, irrigation or bath of sterile hypertonic saline (5 to 10 per cent.), alternating with the neutral solution of chlorinated soda, and a sterile physiologic saline, according to judgment, about as follows: Neutral solution of chlorinated soda one to two hours, hypertonic saline two hours, physiologic saline one hour, and then repeat until lesions appear and extent of injury can be determined. As long as the lesion remains an erythema continue this treatment during the daytime. At night, dry the skin under aseptic precautions, and apply a vanishing surgical cream containing hypochlorous acid or liberating chlorin, of the type of the chlorazene (chloramin-T, 1 per cent. in sodium stearate) surgical cream, or instead, use wet hypertonic saline dressings.

Dusting powders are inadvisable because of crusting and possibility of infection. Chloramin-T and dichloramin-T in full strength powder form are too irritating. The authors have had no experience with Vincent's powder but on general principles would not favor its use. They also advise against the use of silver nitrate, iodin, potassium permanganate, or other local applications. Saturated magnesium sulphate solution proved irritating and no benefits were observed from its use.

In the case of vesicle formation, empty vesicles early under aseptic precautions, by means of a hypodermic syringe or sterile needle with slight pressure on the vesicle, and allow intact vesicle wall to collapse and seal down on its base. After this procedure, continue with alternating neutral solution of chlorinated soda and sterile salines, as above. If vesicles are not drained early, the fluid content may, within four to five hours, coagulate to such an extent that a large coagulum is formed that cannot be removed, and forms a possible medium for bacterial growth. It is very important that skin damaged by mustard gas be protected from trauma. Slight injuries, even ordinary pressures of the body, will cause the development of secondary vesicles or decubitus in the injured areas.

The use of unguents and ointments with oily bases, such as zinc stearate, olive oil, oleum petrolatum, or any form of crude petrolatum or other protecting oil, or such air-excluding and infection-including protectives as oiled paper, paraffin sprays and coatings, such as are employed in the treatment of thermal burns, is strongly condemned in the treatment of dichlorethylsulphid injuries. The principle of excluding the air for the purpose of lessening pain in the treatment of thermal burns is not applicable here because of the relative anesthesia of the dichlorethylsulphid lesions in their earlier stages. Exceptions to the above rule are the sodium stearate impregnated with chloramin-T and the chlorcosane solution of dichloramin-T, as in these cases there is an active and persistent germicidal agent present.

In the case of denuded surfaces with much pain and when bedsores have developed, the colloidal saline bath is strongly advocated. This bath is made as follows: Dissolve 1 pound of commercial cornstarch and 1 pound of sodium bicarbonate in 20 to 30 gallons of sterile physiologic salt solution, at a temperature of 90 to 95 F. The patient can be left immersed in this, when necessary, from fifteen minutes to forty-eight hours. The patient should be constantly watched by the nurse. Should pulse become weak, give strychnin or digipuratum or any other active digitalis preparation, or remove from bath, and apply blankets and heat.

B. Severe Injuries.—When necrosis of the skin, more or less extensive, develops, follow the same line of treatment given above: full bath, irrigation, slush or sponge bath, or wet packs of neutral solution of chlorinated soda, alternating with physiologic and hypertonic salines, or the colloidal bicarbonate bath should be constantly employed. Avoid bedsores. For this purpose the constant colloidal or saline bath with patient hung in canvass body cradle to take off pres-

6. **Production of Meningococcus Anti-Endotoxin.**—Multivalent antimeningococcus serum that has given the best results in military cases has been found to be differentiated from serum of less therapeutic value by the fact that the former contains a demonstrable quantity of anti-endotoxins to each of the two commonest types of the meningococcus. Gordon found that anti-endotoxin is elaborated by the rabbit to both the commonest types of the meningococcus. In order to obtain anti-endotoxin, especially in the case of Type 1 meningococcus, it is absolutely essential to avoid over dosage. The antigens that appear to give best results in the rabbit are neither the raw coccus nor autolysates, but (1) a suspension of the dried coccus, and (2) the sensitized raw coccus.

8. **Gunshot Wounds of Knee Joint.**—Fifty consecutive cases of gunshot wound of the knee joint are summarized by Hepburn. He points out that this series does not include those cases in which the synovial membrane was not found to be penetrated, and at the same time commends the practice of early and complete excision of these nonpenetrating wounds, thereby preventing secondary infection of the joint in a large number of cases. It is a rare occurrence today at the base to find suppuration in a knee joint when the notes from a casualty clearing station say "Wound excised, not penetrating." Of the fifty cases under consideration, twenty-five were complicated by demonstrable bony lesion and twenty-five were not. The synovial cavity is stated to have been washed out and closed in twenty-seven cases—in fourteen cases with fracture and in thirteen without fracture. Saline solution is stated to have been employed in six cases, eusol in six, and ether in two. The remainder were not specified. Bipp was introduced into the joint in two cases and flavine in one; all three did well. The foreign bodies were not found, or not looked for, at the casualty clearing station in nine cases. Five of these required removal at the base. Of the remainder, one was left embedded in the femur, the other three being very small and the joints all quiescent.

It was found necessary to reopen the joint in nineteen cases out of fifty. Of these, twelve were cases with fracture, and seven without fracture. A partial arthrectomy was performed on one patient with extensive loss of the condyles of the femur. Subsequent amputation was necessary in six of the nineteen cases—four with and two without fracture. Of the latter, one was amputated for secondary hemorrhage from a separate wound. Two patients died from septicemia, one in each class. Both were suffering from other severe wounds in addition to those of the knee joint.

Repeated aspiration, with or without lavage through a cannula, has not, in Hepburn's hands, given results which warrant the delay in more complete drainage. It is now his custom to aspirate only once, and if the pathologist reports an active infection, to proceed with freer drainage should the accumulation of pus recur. He has found that suppuration occurs much more frequently in the anterior than the posterior portion of the synovial sac. Absolute immobilization, and evenly distributed support under the popliteal region, are extremely important points in the treatment. When pus does form in the popliteus bursa, thorough drainage is very difficult to obtain. The tendency is for the pus to track downward into the leg on the posterior interosseous membrane as well as upward along the femur, with a bad prognosis. Of the nineteen cases in this series which Hepburn drained by lateral incisions, seven developed an abscess in the posterior pouches. Six of these were treated by incision in the popliteal space, and one by an incision in front of the tendon of the adductor magnus. Four of these subsequently required amputation, and one of the four men died.

The offending organism in all cases reopened was the streptococcus, with or without *Staphylococcus albus*. Hepburn uses a small trocar or a spinal needle for aspiration. He now uses the Thomas knee splint, with about 10 degrees of flexion, and without any extension. A foot support is essential. The postoperative treatment is—two hourly injection of half an ounce of eusol into each of the four Carrel tubes, with one thorough daily irrigation for three days. The tubes may be changed daily if they become blocked. At the third daily dressing the tubes are all removed and replaced by two tubes, which lie in the incisions but not within the synovial sac. On the fourth day the last through-and-through irrigation is given to remove any loose débris. From this time onward only superficial tubes and dressings are employed, and the incisions in the synovial sac encouraged to close. They are usually sealed up by lymph on the fifth or sixth day. If, as sometimes happens, pus collects in the popliteal region it must be dealt with. Movement of the joint must not be encouraged too early on account of the great danger of stirring up and liberating infection.

13. **Administration of Anesthetics to Soldiers.**—Mills advocates an ethyl chlorid-ether sequence as being the best method for induction, and has devised a method of using this sequence. A stopcock is fitted to the foot of the bag and this, connected by rubber tubing with an ether bottle and bellows, forms the simple apparatus which he uses in giving the ethyl chlorid-ether vapor sequence.

20. **Morbid Anatomy of So-Called "Spanish Influenza."**—Hunt says that a blood count is of great value in helping to discriminate between the various causes of P. U. O. (pyrexia of unknown origin). The trench fevers are usually accompanied by a moderate leukocytosis. Malaria, malignant endocarditis, scarlet fever, and cerebrospinal fever, as a rule, show a marked leukocytosis. The enteric group is more usually characterized by a leukopenia. In "Spanish influenza" the leukocyte count usually varies between 5,000 and 9,000 per c.mm. Very few cases of influenza show a true relapse, and the occurrence of pyrexia relapsing within a few days in a supposed case of influenza suggests the probability of the case being one of trench fever.

49. **Treatment of Chronic Osteomyelitis.**—Jean denounces rough handling of the bone, saying that the gouge and chisel are liable to cause remote fissures or at least to deaden the bone tissue and favor production of infection and thrombosis. It is much better to work with an electric drill. When the drill touches a sequester it does not cut into it, but the ear hears the difference in the sound and the hand perceives the contact. Provisional hemostasis is indispensable, and the whole of the bone must be examined. The roentgen negatives taken from front and side must be constantly under the eyes of the operator; roentgenoscopy is not enough to disclose the finer lesions of the osteitis. A head mirror is also indispensable. Curetting is a blind procedure, liable to inoculate sound tissue while neglecting diseased points. He makes no attempt to fill up the cavity, but lines it with the skin loosened up around and drawn down into the cavity and fastened there, then applying a compressing bandage, before arresting the provisional hemostasis. This dressing is removed the fourth or fifth day. If there is still slight infection, he irrigates with Dakin's solution and completes the cure with heliotherapy. If the skin cannot be drawn down to cover the cavity completely, he fills the gap with Reverdin grafts, toward the end of the second week, recommencing a week later the exposures to the sunlight which stimulate the ity of the grafts while continuing the magic effect on the bone lesion and the general condition. By this technic the skin cicatrix is perfect, it is supple and painless. Healing is certain and rapid although the results of this deep cutaneization of the bone, as he calls it, are not esthetic.

50. **Syphilis of Nervous System.**—Sicard and Roger declare that a negative Bordet-Wassermann test of the cerebrospinal fluid excludes general paralysis in dubious cases. This test persists irreducibly positive in general paralysis. In tabes it may veer to negative, and we may be able to modify favorably the course of tabes by intensive treatment. The lymphocytosis and albumin are far less reliable as a basis for the diagnosis. Their experience has confirmed that general paralysis is a special form of meningocerebral syphilis, while tabes belongs in meningomedullary syphilis. The most daring treatments have been given thorough trials in general paralysis, but all to no avail. They have pushed specific treatment to the extremest limits, but without modifying the disease. In one of the cases they describe they gave an intravenous injection of 1.5 gm. neo-arsphenamin, under chloroform anesthesia, followed by a lumbar intraspinal injection of saline or horse serum. The whole procedure, including the chloroform anesthesia, was repeated weekly for two months. The patient bore it well, but the disease showed no improvement.

51. **Colectomy.**—Pauchet relates that further experience is confirming the superior advantages of his aseptic technic for removal of the right colon for obstipation, tuberculosis or cancer. Seven illustrations show the various phases of the intervention.

52. **Serotherapy of Gangrene in the Wounded.**—Mairesse and Régnier write from the automobile surgical Ambulance No. 1 that they have examined bacteriologically 1,016 wounded in a recent three months. Swabs were taken from the deepest part of the wound, the moment the wounded were brought in. Then in fifteen minutes the surgeon was supplied with the bacteriologic balance-sheet for each man, showing not only the microbian flora but the cytologic reaction. They found bacteria of the perfringens type (gas bacilli) present in 297, including twenty-five with sporulated bacilli. All these perfringens wounded were given a prophylactic injection of antiperfringens serum. Of the total 297 anaerobic cases, twenty-five developed gas gangrene. During the early tentative phase of the serotherapy, three of those affected died, but all the others recovered under continued serotherapy, including three exceptionally severe cases. They warn that under the preventive serotherapy, if gangrene develops it has no gas or odor, and the muscles look pink—all tending to lull the surgeon into a false sense of security, unless the case is kept under bacteriologic control. Prompt bacteriologic examination discloses at once the more dangerously infected cases, and these can be given precedence in operating.

53. **Glycuronuria.**—Porak and Texier comment on the instructive oversight of liver functioning afforded by reduction in the glycuronuria, as one of the earliest signs of hepatic incompetency.

54. **Changes in Blood During General Anesthesia.**—Binet compares the publications on this subject in the last few years. They have demonstrated as the most important modifications under the influence of chloroform or ether, a reduction in the activity of the corpuscles, in the coagulability, and also a reduction in the oxidizing power.

55. **Tetanus.**—Bérard and Lumière are in charge of the central service at Lyons for the wounded with tetanus. From 28, 25 and 41 cases during the first years of the war, they had only 15 in 1917, and 3 in 1918, until last month when 4 cases reached them. The clinical picture in their 116 cases, they say, was never twice the same, but all required minute revision of the wounds to clear out débris, etc., with neutralization of the toxins, and treatment of the symptoms as they arose. The wound, the source of the toxin production, may be some minute contused injury of the foot or hand, possibly overlooked entirely. The focus must be widely opened up, curetted and disinfected with oxidizing agents. Crystals of sodium persulphate scattered in the wound were found more useful than hydrogen peroxid solutions, as the action from the crystals kept up longer. Rubber drains must be freely used, and the dressing changed every day. In 26 cases the focus wound had not been disinfected at all, and 19 of this group died. The total mortality, including these cases, was 50 per cent. The protection conferred by the preventive injection rapidly declines, and cannot be counted on for more than two weeks. In 2 of the total 116 cases the production of toxins was evidently so intense that even two injections of the antitoxin, at a week's interval, failed to saturate it. In all the other cases, the 10 or 20 c.c. dose seemed to be ample. When the first symptoms of tetanus appear, they give 30 c.c. of the antiserum daily for three days. When not absolutely certain that all the tetanus bacilli have been cleared out of the wound, they keep up these injections longer.

In symptomatic treatment, the most active and the least dangerous remedy they have found is sodium persulphate. It keeps well, in dry form, in sealed tubes. When ready to use, 5 gm. are dissolved, cold, in 100 c.c. of sterilized distilled water, and 20 c.c. of this is injected into a vein in the bend of the elbow, morning and night, for three days or longer. In about half the cases there is brief vomiting immediately after the injection, so the patient should not eat just before. The spasms usually cease at once after the injection, but may return a few hours later, but often they subside completely after the second or third injection. They have never had any mishaps with it, even under protracted administration. The patient becomes less sensitive to external stimuli, he lies sometimes absolutely calm, free from pain. The relief even for a few hours is a great boon. It is sometimes useful to supplement the action of the persulphate with chloral or other sedative.

The permanent contracture is not appreciably modified by the persulphate. When the contracture affects the muscles of respiration, nothing has been proposed to date that is effectual against this except Sauerbruch's suggestion of bilateral phrenicotomy plus artificial respiration. He has reported several successful cases. Bérard and Lumière believe that the same results might be realized by mere local anesthesia of the phrenic nerves, blocking it with some anesthetic. They have had occasion only once to apply this method, but the success was prompt and complete, respiration becoming normal, the cyanosis, agitation and suffocation disappearing, and the man dropped into tranquil sleep. They injected 10 c.c. of a 1 or 2 per cent. solution of procain, with a little epinephrin, introducing the needle at the posterior margin of the sternocleidomastoid, 2 cm. above the supraclavicular fossa, the tip pointing toward the median line. The needle is gently pushed in for 3 cm. until it encounters a little stronger resistance, showing that it has reached the anterior scalenus. Then the fluid is injected. Local and regional anesthesia in this way will arrest permanent conto the muscles of the urogenital floor. This reenforces the floor and renders it solid and resistant. Separating the bladder from the vagina and the uterus requires minute care. The back and sides of the bladder are detached and the lips of the vaginal incision. The erector muscles are then sutured together on the median line, thus forming a strong floor for the bladder. The urogenital floor is then sutured together below and then the vaginal incision. This method has been applied in six cases of extreme prolapse, and all were radically cured. The interval since has been only a few months but the resistance opposed by the region to abdominal straining guarantees a definite cure. The deep sutures are made with chromicized catgut. There is no need for tamponing the vagina or checking defecation.

34. **Multiple Disseminated Epitheliomatosis in Workers on Tar.**—Thibierge describes the peculiar dermatosis which develops when the openings of the glands in the skin become obstructed by tar, asphalt or similar substance clogging the pores.

35. **Enlarged Photographs in Forensic Medicine.**—Martin is professor of legal medicine at the University of Lyons, and he here expatiates on the valuable information often to be derived from enlarging a photograph of a firearm wound in criminal cases. The stereoscopic view, enlarged several diameters, brings out details which entirely escape notice under other conditions, or are beyond the pale of the human senses otherwise.

36. **Cerebrospinal Fluid in Typhus.**—Devaux asserts, on the basis of 200 cases, that typhus infection is more decidedly neurotropic than in any other infectious disease. The diffusion and gravity of the lesions in the central nervous system are in marked contrast to the relative integrity of the other organs. The cerebrospinal fluid shows a leukocyte reaction early and constantly, and it is progressive and persists for from two to eight months. During the first week the field shows ten or twelve large lymphocytes, four or five mononuclears, and one polymorphonuclear to every two or three fields. This cytologic picture grows graver for two or three weeks.

45 *Diagnosis of Contagious Lesions of Syphilis. Quioc.—p. 73.
46 Oscillometer Localization of Cardiac Murmurs. A. Lévy.—p. 74.

44. **Local Heliotherapy for War Wounds.**—Léo and Vaucher report experiences which show that bacteriologic and histologic research confirms the clinical benefit from local sun baths of war wounds. The microscope discloses the rapid disappearance from the wound of the anaerobic bacteria and then of the aerobic. The profuse exudation of lymph is not bactericidal, but its high antitryptic power neutralizes the fermentation activity of the bacteria and leukocytes. Nothing else, except hot air, induces such an incessant afflux of fresh serum. Phagocytosis does not seem to be activated, at least on the surface. After a certain number of hours of insolation, the wound becomes practically sterile. They declare in conclusion that this effect is realized more rapidly by insolation than by any other therapeutic measure, not even excepting hypochlorite solutions. They reiterate that in all climates and at all seasons, when the sun is shining, it emits rays with a positive therapeutic value. Not to utilize them is a waste, greatly to the detriment of the wounded o whose beds the sunlight falls. The dressing should be opene to expose the wound and the window should be opened, glass arrests part of the useful chemical rays, but coarse wi screening is necessary to keep flies away from the woun They do not think it necessary to protect the wound again dust. The exposures are for fifteen minutes to a maximum two hours. The sunlight acts like a drain, the edemato tissues around the wound pouring out the septic fluid in then the droplets becoming visible to the naked eye in about te minutes, and always by the fifteenth or twentieth. They te the patient, "Put your wound there, in the sunshine, an watch how soon it will begin to ooze and the pain go down. They expose the whole limb when possible, or the region o the body involved.

45. **Simplified Technic for Determination of Pale Spiro chete.**—Quioc expatiates on the superior and unfailing advan tages of the Fontana-Tribondeau technic in the early or lat differential diagnosis of syphilis. The organic débris and re corpuscles are partially dissolved while the pale spirochete i shown up clearly and distinct from other spirochetes.

(1) Dissolve cold 1 gm. silver nitrate crystals in 20 c.c. of distille water. Reserve part of the solution, and add to the rest ammonia a little at a time, stirring constantly, until a sepia precipitate is throw down and then disappears anew. The reserved solution is then added fractioned, until there is slight turbidity, persisting during agitation This reagent, sheltered from light, keeps well. Dry the specime carefully, and cover it for thirty seconds, two or three times, accordin to its thickness, with Ruge's solution: 1 c.c. of crystallized aceti acid in 100 c.c. of a 2 per cent. solution of formaldehyd. The hemo globin dissolves. Rinse in alcohol; pass through flame to burn of all traces of alcohol. Cover the specimen with a solution of tannin: 5 gm. of tannin and 1 gm. of glacial phenol in 100 gm. water. Heat till it steams. Let it steam for a minute, then rinse till all trace of the tannin solution is gone. Then dry. Cover with the nitrate solution. Rinse and dry. All the spirochetes take an even deposit of the silver, and look uniformly thicker and extremely distinct. The pale spirochete retains all its special characteristics, showing up dark purple against a transparent background or against the light yellow background of the decolored reds.

47. **Meningeal Hemorrhages in War Pathology.**—Guillain declares that meningeal hemorrhages play a surprisingly important part in war pathology, especially with skull wounds, and in aviators making a dangerously sudden landing or a fall. If lumbar puncture is not done, the meningeal hemorrhage may escape detection, or symptoms later may retrospectively reveal it. With shell concussion, besides the meningeal hemorrhage there may be bleeding from lungs, nose or stomach. Signs of meningeal hemorrhage include cerebral excitement, with mental confusion, exaggerated tendon reflexes, with bilateral clonus and Babinski, certain contralateral reflexes, and defense reflexes like those in the frog, pupil disturbances such as mydriasis, uneven pupil reactions, disturbance in reaction to light, and massive albuminuria. In some cases, a jaundice tint suggested meningeal hemorrhage even before the lumbar puncture confirmed the assumption. In a number of cases of meningeal hemorrhages, there was an excessively high temperature for several days. This was not due to infection but to some nervous disturbance in the heat production, probably from toxic action by the products generated in the extravasated blood. General anesthesia dilates the vessels and tends to exaggerate the hemorrhage if much of the spinal fluid is withdrawn. Done properly, lumbar puncture has a decided therapeutic value.

49. **Treatment of Chronic Osteomyelitis.**—Jean denounces rough handling of the bone, saying that the gouge and chisel are liable to cause remote fissures or at least to deaden the bone tissue and favor production of infection and thrombosis. It is much better to work with an electric drill. When the drill touches a sequester it does not cut into it, but the ear hears the difference in the sound and the hand perceives the contact. Provisional hemostasis is indispensable, and the whole of the bone must be examined. The roentgen negatives taken from front and side must be constantly under the eyes of the operator; roentgenoscopy is not enough to disclose the finer lesions of the osteitis. A head mirror is also indispensable. Curetting is a blind procedure, liable to inoculate sound tissue while neglecting diseased points. He makes no attempt to fill up the cavity, but lines it with the skin loosened up around and drawn down into the cavity and fastened there, then applying a compressing bandage, before arresting the provisional hemostasis. This dressing is removed the fourth or fifth day. If there is still slight infection, he irrigates with Dakin's solution and completes the cure with heliotherapy. If the skin cannot be drawn down to cover the cavity completely, he fills the gap with Reverdin grafts, toward the end of the second week, recommencing a week later the exposures to the sunlight which stimulate the vitality of the grafts while continuing the magic effect on the bone lesion and the general condition. By this technic the skin cicatrix is perfect, it is supple and painless. Healing is certain and rapid although the results of this deep cutaneization of the bone, as he calls it, are not esthetic.

50. **Syphilis of Nervous System.**—Sicard and Roger declare that a negative Bordet-Wassermann test of the cerebrospinal fluid excludes general paralysis in dubious cases. This test persists irreducibly positive in general paralysis. In tabes it may veer to negative, and we may be able to modify favorably the course of tabes by intensive treatment. The lymphocytosis and albumin are far less reliable as a basis for the diagnosis. Their experience has confirmed that general paralysis is a special form of meningocerebral syphilis, while tabes belongs in meningomedullary syphilis. The most daring treatments have been given thorough trials in general paralysis, but all to no avail. They have pushed specific treatment to the extremest limits, but without modifying the disease. In one of the cases they describe they gave an intravenous injection of 1.5 gm. neo-arsphenamin, under chloroform anesthesia, followed by a lumbar intraspinal injection of saline or horse serum. The whole procedure, including the chloroform anesthesia, was repeated weekly for two months. The patient bore it well, but the disease showed no improvement.

51. **Colectomy.**—Pauchet relates that further experience is confirming the superior advantages of his aseptic technic for removal of the right colon for obstipation, tuberculosis or cancer. Seven illustrations show the various phases of the intervention.

52. **Serotherapy of Gangrene in the Wounded.**—Mairesse and Régnier write from the automobile surgical Ambulance No. 1 that they have examined bacteriologically 1,016 wounded in a recent three months. Swabs were taken from the deepest part of the wound, the moment the wounded were brought in. Then in fifteen minutes the surgeon was supplied with the bacteriologic balance-sheet for each man, showing not only the microbian flora but the cytologic reaction. They found bacteria of the perfringens type (gas bacilli) present in 297, including twenty-five with sporulated bacilli. All these perfringens wounded were given a prophylactic injection of antiperfringens serum. Of the total 297 anaerobic cases, twenty-five developed gas gangrene. During the early tentative phase of the serotherapy, three of those affected died, but all the others recovered under continued serotherapy, including three exceptionally severe cases. They warn that under the preventive serotherapy, if gangrene develops it has no gas or odor, and the muscles look pink—all tending to lull the surgeon into a false sense of security, unless the case is kept under bacteriologic control. Prompt bacteriologic examination discloses at once the more dangerously infected cases, and these can be given precedence in operating.

53. **Glycuronuria.**—Porak and Texier comment on the instructive oversight of liver functioning afforded by reduction in the glycuronuria, as one of the earliest signs of hepatic incompetency.

54. **Changes in Blood During General Anesthesia.**—Binet compares the publications on this subject in the last few years. They have demonstrated as the most important modifications under the influence of chloroform or ether, a reduction in the activity of the corpuscles, in the coagulability, and also a reduction in the oxidizing power.

55. **Tetanus.**—Bérard and Lumière are in charge of the central service at Lyons for the wounded with tetanus. From 28, 25 and 41 cases during the first years of the war, they had only 15 in 1917, and 3 in 1918, until last month when 4 cases reached them. The clinical picture in their 116 cases, they say, was never twice the same, but all required minute revision of the wounds to clear out débris, etc., with neutralization of the toxins, and treatment of the symptoms as they arose. The wound, the source of the toxin production, may be some minute contused injury of the foot or hand, possibly overlooked entirely. The focus must be widely opened up, curetted and disinfected with oxidizing agents. Crystals of sodium persulphate scattered in the wound were found more useful than hydrogen peroxid solutions, as the action from the crystals kept up longer. Rubber drains must be freely used, and the dressing changed every day. In 26 cases the focus wound had not been disinfected at all, and 19 of this group died. The total mortality, including these cases, was 50 per cent. The protection conferred by the preventive injection rapidly declines, and cannot be counted on for more than two weeks. In 2 of the total 116 cases the production of toxins was evidently so intense that even two injections of the antitoxin, at a week's interval, failed to saturate it. In all the other cases, the 10 or 20 c.c. dose seemed to be ample. When the first symptoms of tetanus appear, they give 30 c.c. of the antiserum daily for three days. When not absolutely certain that all the tetanus bacilli have been cleared out of the wound, they keep up these injections longer.

In symptomatic treatment, the most active and the least dangerous remedy they have found is sodium persulphate. It keeps well, in dry form, in sealed tubes. When ready to use, 5 gm. are dissolved, cold, in 100 c.c. of sterilized distilled water, and 20 c.c. of this is injected into a vein in the bend of the elbow, morning and night, for three days or longer. In about half the cases there is brief vomiting immediately after the injection, so the patient should not eat just before. The spasms usually cease at once after the injection, but may return a few hours later, but often they subside completely after the second or third injection. They have never had any mishaps with it, even under protracted administration. The patient becomes less sensitive to external stimuli, he lies sometimes absolutely calm, free from pain. The relief even for a few hours is a great boon. It is sometimes useful to supplement the action of the persulphate with chloral or other sedative.

The permanent contracture is not appreciably modified by the persulphate. When the contracture affects the muscles of respiration, nothing has been proposed to date that is effectual against this except Sauerbruch's suggestion of bilateral phrenicotomy plus artificial respiration. He has reported several successful cases. Bérard and Lumière believe that the same results might be realized by mere local anesthesia of the phrenic nerves, blocking it with some anesthetic. They have had occasion only once to apply this method, but the success was prompt and complete, respiration becoming normal, the cyanosis, agitation and suffocation disappearing, and the man dropped into tranquil sleep. They injected 10 c.c. of a 1 or 2 per cent. solution of procain, with a little epinephrin, introducing the needle at the posterior margin of the sternocleidomastoid, 2 cm. above the supraclavicular fossa, the tip pointing toward the median line. The needle is gently pushed in for 3 cm. until it encounters a little stronger resistance, showing that it has reached the anterior scalenus. Then the fluid is injected. Local and regional anesthesia in this way will arrest permanent contracture of the limbs in tetanus, and ward off vicious consolidation of fractures in the wounded with tetanus, while shortening the period of functional impotence with partial tetanus. If constipation persists in spite of the above measures, the bowels and sphincters may be relaxed by spinal anesthesia and contracture around the wound relieved by regional anesthesia.

In conclusion they report an instructive case in an American soldier with a scrap of shell in the right scapula region. The projectile was not found at the primary operation, and it seemed to be healing harmlessly in place when, after a month, contracture was noticed in that arm and pain in the muscles of the shoulder and neck. Massage and passive movements were applied but, the symptoms growing worse, the young man was sent to the tetanus service. At once the projectile and sequesters were sought and removed, and the tetanus bacillus was cultivated from them. This patient's condition is still precarious. He was wounded July 15, and was given two antitetanus injections. The first hint of contracture came August 8, but the projectile was not removed till August 20. At the first hint of contracture, the wound should have been cleared out of all foreign bodies. During the twelve day interval the toxins had been elaborated without check.

57. **Colorimetric Scale for Wassermann Reaction.**—Bergeron and Normand extol the advantages of having an additional set of ten tubes for comparison and percentages of the gradation of tints in the Wassermann reaction. The supplementary set of tubes contain varying dilutions in physiologic saline of a 20 per cent. dilution of the original 10 per cent. dilution of 0.2 c.c. of sheep or human red corpuscles. Comparison between the findings of different workers and different laboratories is thus made possible and reliable.

63 *Artificial Arms and Hands. C. Roederer.—p. 279.
64 Congenital Absence of Right Diaphragm. L. Moreau.—p. 281.
65 *Suicidal Forms of Psychoses. H. Damaye.—p. 284.

58. **Paralysis from Concussion of Spinal Cord.**—Roussy and Cornil analyze five cases, representing different types, to illustrate the necessity for reserving the prognosis at the first examination. Cases apparently of the gravest nature may prove to be the result of merely temporary suspension of function, and gradual recuperation follows. Systematic immobilization, refraining from any operation on the spine, care to ward off bedsores and complications on the part of the lungs, will often lead to a favorable outcome in cases of quadriplegia from concussion of the spinal cord. In three of the cases described signs of return of motor function were detected between the twentieth and twenty-fourth day. The concussion was by contre-coup or indirect contusion. In the two cases with direct contusion of the cord and dislocation of a vertebra, the interval was two and four months. These two men, ten and fourteen months after the wound, present merely simple hemiparesis or traces of hemiplegia, with the Claude-Bernard Horner syndrome. In the ten months case the sphincter and genital derangement still persist.

63. **Working Hands.**—Roederer reviews the present tendencies in the manufacture of artificial hands, simplification of all parts, especially the shoulder piece, buckling instead of lacing, abandonment of the "universal prosthesis," specialization to the extremest limits in the terminal portion, and the discrimination between the *prothèse de forme* and the *prothèse de force*. At the Lyons training school for the disabled, 75 per cent. of the 286 farmers among the 637 one-armed men have returned to agricultural work. Of the 175 factory workers, 15 per cent. had resumed their former trade, and 29 per cent. a similar trade; 9 per cent. had taken up agricultural work

65. **Suicidal Mental Derangement.**—Damaye relates that among the 916 men who have passed through the advanced neuropsychiatric center, there were thirty-three who had to commit suicide. In fifteen of the thirty-three, there were evidences of heart disease, with traces of albumin, as also in seven with melancholia but no attempts at suicide. The tendency to mental derangement was most often manifested in the man's deserting. Malaria plus abuse of alcohol was found in the large majority of these cases. Many of these men are peculiarly susceptible to liquor so that even one glass of wine upsets their balance, and fatigue enhances this susceptibility. Brief summaries are given of each of the suicide cases. The treatment applied to all aimed at disintoxication and reconstitution: iodin, cacodylate, morphin, and daily baths at 37 or 40 C. (104 F.) for half an hour or an hour.

68 *Berberin in Treatment of Malaria. A. Ilvento.—p. 358.
69 *Treatment of Lymphosporidiosis. G. Alessandrini.—p. 364.

68. **Berberin in Treatment of Malaria.**—Ilvento urges trial on a large scale of decoctions of barbery which is an old household remedy for malaria in Italy. Used in conjunction with quinin, it has given him better results than was obtained with the latter alone.

69. **Tartar Emetic in Treatment of Sporidiosis in Horses.**—Alessandrini reports the cure of over 89 per cent. of 105 horses with cryptococcus farcy (lymphosporidiosis) given intravenous injections of tartar emetic. It also displayed preventive action when the lesions were washed with it and the "buttons" opened. Flies disseminate the germs and may infect sound animals when they alight close to the eyes and nostrils or on excoriations. The flies that get any of the tartar emetic from the lesions or otherwise die promptly. Even in a very weak, sweetened solution it soon kills them.

77 *Skin Tunnel for Kinetic Plastics. F. Delitala.—p. 411.
78 Prostheses with Kinetic Plastics. Landini and Cevolani.—p. 417.

71. **Cervical Ribs.**—Scalone reviews the present status of our knowledge of cervical ribs, the differential diagnosis of disturbances from them, and the best mode of treatment. In a personal case described, almost the entire supernumerary rib was resected through a short incision close to the base of the neck at the side. The rib was cut and removed in two parts. The patient was a young soldier, and the cervical rib was adherent to the first regular rib. There had been no disturbance from the unsuspected cervical rib until within the last few months.

73. **Operations on Nerves.**—Corti discusses the various procedures that have been devised to protect the nerve after an operation on it, and describes personal research which has apparently demonstrated that an artery from a dog can serve to protect a wounded nerve and it resists absorption for a long time. In three clinical cases it was found in good condition after 225, 194 and 305 days. Veins are less resistant than arteries for the purpose. The sheet of arterial tissue wrapped around the nerve protects it from invasion by surrounding tissue.

77. **Kinetic Plastics.**—Delitala's photographs show the simple technic for cutting a bridge flap, rolling the sides up to form a tunnel, and then looping around the outside of the tube thus formed the tendons of the chief muscles. The distal ends of the tendons are brought up and each is looped around the belly of the respective muscle, and fastened with

a few stitches. The skin is then sutured over the whole. The handle of an instrument, passed through the tunnel thus [illegible] can then be moved by volitional impulse from those muscles.

79 Tuberculosis in Soldiers. A. Brungnatelli.—p. 821.
80 *Xiphoid Crepitation in Typhoid. F. Bergolli.—p. 823.
81 *Prophylaxis of Malaria. D. Albano.—p. 826.

80. **Xiphoid Crepitation in Typhoid.**—Bergolli reports twelve cases of typhoid in which Galvagni's sign—xiphoid crepitation—was pronounced. Some were acute cases and the liver was generally enlarged, and there were usually symptoms of a reaction on the part of the peritoneum. In all the cases the epigastrium bulged above the level of the xiphoid. The seat of the crepitation is undoubtedly the subcutaneous cellular tissue, and disturbances in the circulation of lymph seem to be the cause.

81. **Prophylaxis of Malaria.**—Albano relates that mosquitoes will not bite where the skin is smeared with petrolatum. He smears all the exposed skin with petrolatum once every day or two, and says that this permits tranquil sleep amid myriads of mosquitoes.

89 *Mumps Meningitis. V. Zerbino.—p. 44.
90 *Secondary Pneumococcus Meningitis. L. Solari.—p. 50.
91 *Pneumonia in Twenty-Five Days' Infant. M. A. Ugon.—p. 54.
92 Protection of Children against Tuberculosis. A. Alfaro and V. Blanco.—p. 57.

83. **Serotherapy of Poliomyelitis.**—Acuña and Casaubon report four cases of poliomyelitis in which convalescents' serum was used in treatment. They expatiate on the logical and promising outlook for this form of treatment although their own cases were disappointing, as the disease was in an advanced phase in all, paralysis having been observed for five or seven days before. Four days seems to be the limit and the more recent the convalescence in the donor the more effectual the serum although instances are known of effectual action even after a thirty-two years' interval. In their four cases the intraspinal injection of the serum was borne without apparently the slightest inconvenience. The infants were from 7 to 20 months old, and the amounts injected ranged from 2 to 6 c.c. at a time, to a total of from 7.5 to 38 c.c. The interval since the convalescence had been three, five and eight years and two months.

84. **Kidney Colics in Child.**—The boy of 6 had suffered for three years from colic pains, finally explained by roentgen discovery of two concretions in the pelvis of the left kidney. There never had been any hematuria, pyuria or albuminuria, and the general health was excellent throughout.

88. **Infantile Scorbutus.**—The child was about a year old, and it had been fed almost exclusively for weeks with boiled milk and arrowroot flour.

89. **Mumps Meningitis.**—Zerbino's patient was a boy of 13, and the diagnosis when he entered the hospital had been tuberculous meningitis. After he had been feeling sick for two weeks and lumbar puncture had showed 384 cells per millimeter, including 99 per cent. lymphocytes, he began to improve. A history of mild mumps two weeks before was then elicited. In some cases cited, the meningitis was the first manifesation of the disease.

90. **Pneumococcus Meningitis.**—The boy of 3 had recovered from bronchopneumonia when, a month later, he developed fatal pneumococcus meningitis.

91. **Pneumonia in Infant.**—The nursling was only 18 days old when it developed pneumonia, with defervescence the ninth day and complete recovery, after a brief tardy partial bronchopneumonia in the base of the same lung. Treatment had been with hot baths and 1 c.c. of 5 per cent. camphorated oil.

Cronica Medica, Lima

August, 1918, **35**, No. 662

93 Exophthalmic Goiter in Girl of Sixteen. E. Odriozola.—p. 219.
94 *Treatment of Varicocele. H. H. Torres.—p. 225.
95 Preparation of Sodium Hypobromite. M. A. Velasquez.—p. 235.

94. **Conservative Treatment of Varicocele.**—Torres reports highly favorable results in fourteen cases in which he applied del Valle's conservative method of curing varicocele. He separates the spermatic veins into two bunches and passes a silk ligature around part of the veins in each bunch. The long ends of the silk are then drawn up through an incision in the aponeurosis, 4 cm. long, made 2 cm. inside of the internal pillar. The veins thus drawn up through the aponeurosis are held there while the incision in the aponeurosis is sutured beneath them, except at the corners. These veins thus run over a bridge, materially shortening their extent below, and sustaining the testicle at the proper height, while the circulation is modified to prevent further tendency to varicocele, without a cutting operation. Several illustrations show the details of the technic.

99 Sneezing: Spontaneous and Induced. V. de Castro.—p. 276.

97. **Disturbance from Foreign Body in Intestine.**—Intense pain in the appendix region, with tenderness at McBurney's point, were the only symptoms. They kept up for three days and then subsided for six years, when the pain returned with agonizing intensity, until the tooth of a comb was passed in the stools. This cleared up the puzzling diagnosis and all the disturbances at one stroke.

Revista de la Asociacion Medica Argentina, Buenos Aires

July, 1918, **29**, No. 164

100 *Gastro-Enterostomy for Simple Ulcer. C. B. Udaonda.—p. 5.
101 History of Hygiene in Argentina. E. R. Coni.—p. 15. Cont'n.
102 *Partial Colectomy. D. Decoud and G. B. Arana.—p. 55.
103 *Angular Pregnancy. C. Mönckeberg.—p. 69.
104 Pelvic Gummatous Cellulitis. M. R. Castex.—p. 84.
105 *Treatment of Inaccessible Fistulas. A. Turenne.—p. 95.
106 Tuberculosis. J. J. Viton.—p. 108. To be continued.

100. **Remote Results of Gastro-Enterostomy for Simple Ulcer.**—Udaonda reports the remote results in twenty-two out of seventy-one operative cases of simple, noncomplicated gastric ulcer followed for from one to four years. Only 27.24 per cent. are free from stomach disturbances. All the others have had the old subjective symptoms return, as severe as before and as rebellious to treatment. The symptoms returned after intervals ranging from three months to two years; the average, between the sixth and tenth months. There has been hematemesis in 16 per cent. and occult blood has been found in over 86 per cent. The gastro-enterostomy opening seems to be working perfectly in all. Only in one case is there suspicion of syphilis, and there is nothing to suggest jejunal ulceration in any case. In his nonoperative cases, fully as good results were obtained with medical treatment alone.

102. **Colectomy.**—Decoud and Arana report two superposable cases in which a tumor compelled resection of part of the ileum and colon. Stereoscopic radiography aided materially in the diagnosis.

103. **Angular Pregnancy.**—Mönckeberg describes the anatomic conditions involved as the fetus develops in the tubal angle just inside the uterus. In diagnosing this site, the hardening of the tumor as the uterus contracts is instructive, also that the tumor is on one side and toward the front, while the round ligament lies outside of the tumor when examined under an anesthetic. The angular pregnancy tumor also

feels soft in comparison to the hard or fluctuating tubal pregnancy tumor. On suspicion of an angular pregnancy, expectancy should be the rule. By the fourth or fifth month the uterus regains its symmetrical outline and the pregnancy runs the usual course. It is better in a dubious case to annoy the patient by examination several times in succession instead of overhasty decision to operate on assumption of a tubal pregnancy.

105. **Inaccessible Vesicovaginal Fistulas.**—Turenne reports gratifying success in two cases of this kind in which he applied the technic described in 1910 by Gray-Ward.

Revista Española de Medicina y Cirugia, Barcelona

107 Nephrolithiasis and Roentgen Examination. R. Lozano and E. Pastor.—p. 109.
108 *Slow Malignant Endocarditis. G. Roqueta.—p. 116.
109 *Improved Histologic Staining Technic. P. del Rio-Hortega.—p. 124.

108. **Slow Malignant Endocarditis.**—Roqueta's patient was a young woman whose father had succumbed to angina pectoris, and whose sister and brother present mitral lesions. She had two attacks of appendicitis in 1917, and the endocarditis followed close on the removal of the appendix, with death in seven months. A colored plate shows the numerous colonies of the *Streptococcus viridans* in pure culture from the blood.

109. **Improved Staining Technic.**—Rio-Hortega gives the details of a method for staining histologic specimens with an ammoniacal solution of silver carbonate, prepared with lithin carbon. [illegible] silver nitrate. The details of structure are shown up, he says, much clearer than with the classic technics. It is particularly useful in amylosis and in study of nerve fibers and tumors.

114 *Chorea. V. Ortiz.—p. 323.
115 Ankylostomiasis. C. Muniagurria.—p. 325.

113. **Roentgen Amenorrhea.**—A girl of 14, robust and of a good family, swallowed a needle, and was examined for half an hour with the roentgen rays, which entailed a severe dermatitis. She had been menstruating regularly for nearly two years, but since the roentgen exposure there has been no menstruation. The third month she began to have severe headaches and at times abdominal pain, especially in the left flank. Ovarian treatment, mustard foot baths and purgatives, applied at the approximate menstrual dates have given no result to date.

114. **Chorea.**—Ortiz emphasizes the prompt cure under sodium salicylate in the two cases reported.

Revista Medica del Uruguay, Montevideo

July, 1918, **21**, No. 7

116 *Diagnosis of Incipient Tabes. P. Scremini.—p. 345.
117 *Disinsertion of the Mesentery. L. Merola.—p. 366.
118 Blindness from Thyroid Deficiency. J. C. M. Fournier.—p. 382.
119 Primary Hemiplegia. P. E. Nuñez.—p. 395.
120 Favorable Experiences with Thymic Acid in Treatment of Cholelithiasis. J. S. Larraya.—p. 402.

116. **Diagnosis of Incipient and Incomplete Tabes.**—Scremini ascribes decisive importance to the *lumbar puncture* fluid for the diagnosis of tabes, even when the Wassermann reaction is negative. Changes in the cell content, chemical and biologic changes, isolated or alone, reveal the chronic syphilitic meningitis, and suggest impending or established tabes. The diagnosis may thus be possible in the preclinical phase. He insists that search for syphilis should be the routine preliminary in every case of nervous disturbance, whatever its nature. The Argyll Robertson is an almost certain sign of syphilis.

117. **Disinsertion of the Mesentery.**—Merola describes a method of access to the retroperitoneal region which retraces, as it were, the steps of embryonal devel[illegible] illustration shows how this *pan-operatoria retroperitoneal* al *the entire adult mesentery* with the ascending mesocolon half of the transverse mesocolon to be detached, with branches of the superior mesenteric artery—and all this out hemorrhage.

Semana Medica, Buenos Aires

June 13, 1918, **25**, No. 24

121 *Infant Death Rate. U. Fernandez.—p. 657.
122 *Liver Incompetency and Surgery. A. Gutierrez.—p. 661.
123 Guinea-Pigs in Testing for Tubercle Bacilli in Milk. E. I —p. 669.
124 Order of Examination of Respiratory Apparatus. A. Vit p. 670.
125 *Medical School Inspection. E. R. Coni.—p. 672.

121. **Infant Mortality.**—Fernandez states in this address puericulture that the death rate of infants under 2 avera 35 per cent. of the total mortality in all countries. Arg tina with its 36 per thousand natality and 15 per thous general mortality ranks high among nations, but the inf death rate is high, 21 per cent.

122. **Insufficiency of the Liver from Surgical Standpoint** Gutierrez gives at noon a pill of 2 mg. of methylene blue test the functional capacity of the liver. The urine is exa ined at 9 p. m., 7 a. m. and noon. The findings in six ca are listed to show the great value of the information tl derived, in regard to the functioning of the liver, and a guide to the surgeon.

125. **Medical School Inspection in Argentina.**—Coni remai that the Argentine Republic was the first country in La America to introduce hygienic and medical school inspecti This was in 1881, and in 1886 the national board of educati officially appointed two physicians for the purpose, and number has been constantly increasing since. Chile intı duced medical school inspection in 1900, appointing a wom physician as the official school inspector. Dr. S. B. Rodrigı introduced it several years ago in Uruguay. In Brazil t cities of Rio and S. Paulo have had official medical schc inspection since 1912. Coni outlines the next steps to taken for the welfare of the young.

Siglo Medico, Madrid

Aug. 3, 1918, **65**, No. 3373

126 *Enteritis and Colon Bacilli. D. F. Murillo.—p. 609.
127 Experimental Stimulation of Pneumogastric Nerve. M. B. Gar —p. 611. Cont'n.
128 Fatal Hemorrhage a Week after Stab Wound of Spleen. J. Pal car and S. Pascual.—p. 615.
129 Public Health in Spain. C. M. Cortezo.—p. 624.

126. **Acute Enteritis at Madrid.**—Murillo reports a famil epidemic of acute enteritis in which he isolated from t stools bacilli which seemed to be intermediate between t colon bacillus and those of the typhoid group. The tox generated by it was exceptionally virulent, but there we no deaths and the cases were scattered over nine days.

Vida Nueva, Havana

June, 1918, **10**, No. 6

130 Hygiene for Munitions Workers. R. de Castro.—p. 173.

August, 1918, **10**, No. 8

131 *Quinin as Palliative in Cancer. V. Delfino.—p. 226.
132 Artificial Plasmogenesis. I. Castellanos.—p. 230.

131. **Quinin for Cancer.**—Delfino does not report a specific case histories, but expatiates in general terms on t great improvement in malignant disease under systemat deep intramuscular injections of small doses of quinin, we diluted, according to Castaigne's technic. The maligna disease proceeds on its inevitable course, but the cancer los its distressing features, he says, and the patient is imme surably relieved, possibly buoyed up for months with an ill sion of recovery.
